Abstract: The lack of transparency in financial reports has several reasons, but the most important is earnings management practice which is implemented by managers. Indeed, managers by using Earnings Management tools manipulate accounting information to achieve some goals. Corporate governance, whose primary goal is to deal with identifying potential mechanisms in which the shareholders of a corporation have more power and exercise to control over the managers to protect their interests, has recently brought the acute attention of academics and policymakers around the world. Most researches have been concentrating on the relationship between corporate governance and firm performance, but a few studies have regarded the moderator functionalities of corporate governance on firm performance from different aspects. This study investigates whether corporate governance affects the relationship between earnings management and corporate performance (ROE) by using listed companies' data in Bursa Malaysia. Data from FTSE Russell has been used by applying the intersection function to the constituents of FTSE Top 100 Bursa Malaysia during the years 2011 to 2015, which includes 59 companies in the form of 295 company-year. The results show that discretionary accruals (DAs) have a significantly negative effect on (ROE) return on equity in the case of lack of consideration corporate governance moderating effect. on the other hand, by considering the moderating influence of corporate governance variables, this equation has been changed, and the negative impact of earning management effects turns to neutral on ROE It implies that managers in weakly governed firms are more likely to abuse accounting discretion than those in strongly governed firms, leading to decreased firm performance. Managers prefer using DAs to window-dress financial earnings, but this causes a more significant reversal of corporate value in the subsequent period.
Key words: Corporate governance; Earnings management; Corporate performance; ROE; Discretionary current accruals

1 Introduction

The increasing pace of globalization, the deregulation and integration of capital markets in 1997, the world witnessed what came to be known as the South East Asian financial crisis (Mitton, 2002). When all the ASEAN (Association of Southeast Asian Nations) countries ranging from Thailand to South Korea faced an economic crisis, which led to a deceleration of economic growth in the area(Lemmon & Lins, 2003). The series of recent financial scandals around the world, and the spectacular corporate collapses which took place in Europe and the USA (e.g., WorldCom, Enron, Parmalat, and Xerox), have driven the previously robust debate on how to reduce the conflict between shareholders and managers and draw an efficient corporate governance system that will encourage sustainable economic growth. (Grant & Visconti, 2006)

The growing importance of a robust corporate governance regulatory structure gathered momentum after the events aforementioned. Furthermore, corporate governance, whose primary goal is to deal with identifying potential mechanisms in which the shareholders of a corporation have more power and exercise control over the managers to protect their interests, has recently brought the acute attention of academics and policymakers around the world. As a response to such scandals, and as a primary approach of protection for shareholders and stakeholders, an explicit strategy has developed concerning public listed companies adopting proper corporate governance standards. In fact, listed companies in most major markets throughout the world are now required to take high corporate governance standards. Particular attention is given to the corporate governance as it is widely regarded as one of the critical mechanism which affects firm performance. (Brav, Jiang, Partnoy, & Thomas, 2008)

Next, a brief overview of the evolution of the Malaysian Code on Corporate Governance is given. Here, this study aims to illustrate how corporate governance could be affected by the relationship between earnings management and firm performance and which part shall have more effects on this

equation. However, by referring to previous research findings and also recent incidences of corporate performance and earning management, this study challenges the notion of effective corporate governance monitoring in Malaysian listed companies. In this dissertation, it will address two critical related questions on governance and firm performance, which have not been adequately answered in the existing academic literature. Individually, it will be examined (1) whether governance changes lead to an effect on the correlation between earning management and substantial performance changes, and (2) what causes firms to change their governance. This study will cover the academic literature related to this topic and, in particular, review the corporate governance mechanisms literature, focusing mainly on the agency theory impact. The significance of this study academically and practically will be demonstrated and established through further discussion. This introductory chapter will present the study background, its objectives, importance, and significance.

2 Model One

First of all, the relationship of DAC and ROE has analyzed by panel data diagnostic tests the results present the strong effects of DAC on ROE, in continue this study will test the relationship of DAC and ROE by considering the effects of corporate governance variable as moderator.

$$ROE_{it} = \alpha_0 + B_1 DAC_{it} + B_2 LEV_{it} + B_3 LMV_{it} + B_4 MB_{it} + e_{it}$$

Where

– αi (i=1…n) is the unknown intercept for each entity (n entity-specific intercepts).
– ROE it represents Return on equity as dependent variable (DV) where i = entity and t = time.
– DAC it represents Earning Management as moderator variable (IV),
– LEV it represents Leverage as control variable (CV),
– LMV it represents Log Market Value as control variable (CV),
– MB it represents Market-to-Book Value as control variable (CV),
– $\beta 1$ is the coefficient for that IV,
– eit is the error term

3 Data and Methodology
3.1 Methods of diagnostics tests
This chapter is going to describe the main finding of the data analysis. First, this study represents the descriptive statistics related to all variables which consist of the independent, dependent, control and mediator variables. Second, the results of diagnostics tests regarding the test of each hypothesis will be explained. The following diagnostic tests have been applied to test the hypothesis; VIF test has been used to examine multicollinearity, F-Limer test has been applied to choose pooled or panel model, Hausman test determines which model should be used if the result in last test (F-Limer) is panel data.

There are two options (Fixed effects & Random effects). In this step base on the fixed or random effects, the further tests will be changed. If the random effects are selected as results of the Hausman test so, if the random effects have been chosen, the Breusch and Pagan Lagrangian multiplier test should be applied to find out the pooled or random effects which will be selected. In this step, if random effects have been selected same as fixed effect model, it must check heteroskedasticity& autocorrelation of the variables for each model. In the end, the final model of each hypothesis will be tested to find out the coefficient of each variable on the model. The below diagrams explain the analysis steps.

3.2 Discussing model two
Hypothesis: Corporate governance activities have a practical effect on the relationship among earning management and ROE inside the listed companies in Bursa Malaysia.

$$ROE_{it} = \alpha_0 + B_1 DAC_{it} + B_2 CEOD_{it} + B_3 DS_{it} + B_4 SBS_{it} + B_5 BM_{it} + B_6 SBM_{it} + B_7 ID_{it} + B_8 NID_{it} + B_9 FO_{it} + B_{10} SX_{it} + B_{11} WB_{it} + B_{12} AMG_{it} + B_{13} NRCM_{it} + B_{14} LEV_{it} + B_{15} LMV_{it} + B_{16} MB_{it} + u_{it}$$

Where
– α_i (i=1…n) is the unknown intercept for each entity (n entity-specific intercepts).
– ROE_{it} represents Return on equity as dependent variable (DV) where i = entity and t = time.
– DAC_{it} represents Earning Management as moderator variable (IV),
– $CEOD_{it}$ represents CEO Duality as moderator variable (MV),
– DS_{it} represents Board size as moderator variable (MV),
– SBS_{it} represents Supervisory Board Size as moderator variable (MV),
– BM_{it} represents Board Meetings as moderator variable (MV),
– SBM_{it} represents Supervisory Board Meetings as moderator variable (MV),
– ID_{it} represents %Independent Directors as moderator variable (MV),
– NID_{it} represents % Non-independent Directors as moderator variable (MV),
– SX_{it} represents % Shares Executives as moderator variable (MV),
– FO_{it} represents % Foreign Ownership as moderator variable (MV),
– WB_{it} represents women on board as moderator variable (MV),
– AMG_{it} represents Annual general meeting as moderator variable (MV),
– $NRCM_{it}$ represents Nomination and remuneration committee meeting as moderator variable (MV),
– LEV_{it} represents Leverage as control variable (CV),
– LMV_{it} represents Log Market Value as control variable (CV),
– MB_{it} represents Market-to-Book Value as control variable (CV),
– $\beta 1$ is the coefficient for that IV,

– uit is the error term

4 Results
4.1 VIF test

Variance inflation factors range from 1 upwards. The numerical value for VIF tells (in decimal form) what percentage the variance (i.e., the standard error squared) is inflating for each coefficient(O'brien, 2007). For example, a VIF of 1.9 tells that the variation of a coefficient is 90% bigger than what would expect if there was no multicollinearity — if there was no correlation with other predictors.

A rule of thumb for interpreting the variance inflation factor:

1 = not correlated.

Between 1 and 5 = moderately correlated.

More significant than 5 = highly correlated.

Exactly how large a VIF has to be before it causes issues is a subject of debate. What is known is that the more VIF increases, the less reliable regression results are going to be. In general, a VIF above 10 indicates high correlation and is cause for concern. Some authors suggest a more conservative level of 2.5 or above.

Sometimes a high VIF is no cause for concern at all(O'brien, 2007). For example, it can get a high VIF by including products or powers from other variables in the regression, like x and x2. If it has high VIFs for dummy variables representing nominal variables with three or more categories, those are usually not a problem. The result of the VIF test and tolerance for each model(hypothesis) has been calculated in Stata 12.1.

4.2 F-limer test

First of all to test the model must be tested to determine we have to continue as pool or panel data(Ebrahimi& Aghaei Chadegani, 2011). The flimer test has been done, and the prob 0.0000 shows that the H0 which represent pool method will be rejected because the prob is less than 0.05 further test to determine that we must continue base on the fixed effect or random effect, it will be done by Hausmantest in continue for this hypothesis.

4.3 Hausman test

In continue to find out which model is proper for this hypothesis after the result of F-Limer test which shows that the panel model is suitable to test this hypothesis now it turns to select between the random or fixed effect, to reach this purpose the Hausman test has been done(Hausman& Taylor, 1981). The result shows the prob-value which represents 0.8257, and this value is more than 0.05, so the H0(random effects) will not be rejected, and random effect has been chosen. In the case of p-value, less than 0.05 the null hypothesis will be rejected, and H1(fixed effects) is the proper way of analyzing the final model. For further tests, the result of this step will determine which method of analysis will be selected to test heteroskedasticity, but the test auto-correlation Wooldridge test has been applied for both assumption (fixed and random), which the result could be quite same.

= 0.38
Prob>chi2 =   0.8257

4.4 Breusch and pagan lagrangian multiplier test

In statistics, the Breusch–Pagan test, developed in 1979 by Trevor Breusch and Adrian Pagan, [1] is used to test for heteroskedasticity in a linear regression model(Breusch& Pagan, 1980). It was independently suggested with some extension by R. Dennis Cook and Sanford Weisberg in 1983. [2] It tests whether the variance of the errors from a regression is dependent on the values of the independent variables. In that case, heteroskedasticity is present. (White, 1980)

This is the basis of the Breusch–Pagan test. It is a chi-squared test: the test statistic is distributed $n\chi^2$ with k degrees of freedom. If the test statistic has a p-value below an appropriate threshold (e.g., $p<0.05$) then the null hypothesis of homoskedasticity is rejected, and heteroskedasticity assumed.

If the Breusch–Pagan test shows that there is conditional heteroskedasticity, one could either use weighted least squares (if the source of heteroskedasticity is known) or use heteroscedasticity-consistent standard errors.(Breusch & Pagan, 1980)

The result of this test will determine between pool method or random effect which one is proper because the p-value less than 0.05 will reject the null hypothesis which is pool method but the value of more than 0.05 will proof that the null hypothesis is proved

Table 5   Breusch and Pagan Lagrangian Multiplier Test for Model Two

ROE[cross,t] = Xb + u[cross] + e[cross,t]

Estimated results:

| | Varsd = sqrt(Var) |

---------+----------------------------

| ROE | .0877692   .2962586 |

| e | .0088847   .0942588 |

| u | .0016563   .0406971 |

Test: Var(u) = 0

chibar2(01) =   5.91

Prob> chibar2 =   0.0075

4.5 Heteroscedasticity test result

In statistics, maximum likelihood estimation (MLE) is a method of estimating the parameters of a statistical model, given observations. MLE attempts to find the parameter values that maximize the likelihood function, given the observations(White, 1982). The resulting estimate is called a maximum likelihood estimate, which is also abbreviated as MLE.

The method of maximum likelihood is used with a wide range of statistical analyses. As an example, suppose that we are interested in the heights of adult female penguins, but are unable to measure the height of every penguin in a population (due to cost or time constraints). Assuming that the heights are normally distributed with some unknown mean and variance, the mean and variance can be estimated with MLE while only knowing the heights of some sample of the overall population. MLE would accomplish that by taking the mean and variance as parameters and finding particular parametric values that make the observed results the most probable given the normal model(White, 1982).

From Bayesian inference, MLE is a particular case of maximum posterior estimation (MAP) that assumes a uniform prior distribution of the parameters. In frequentist inference, MLE is one of several methods to get estimates of parameters without using prior distributions. Priors are avoided by not making probability statements about the parameters, but only about their estimation, whose properties are entirely defined by the observations and the statistical model. The results of this tests for this hypothesis present Lagrange Multiplier LM Test p-value of 0.000, Likelihood Ratio LR Test p-value of 0.000 and Wald test p-value of 0. 000.(Vuong, 1989)in all these tests H0 has been rejected which represents Panel Homoscedasticity, so the model has Panel GroupWise Heteroscedasticity.

Table 6   Panel Group Wise Heteroscedasticity Test for Model Two

* Panel GroupWise Heteroscedasticity Tests		
Ho: Panel Homoscedasticity - Ha: Panel GroupWise Heteroscedasticity		
- Lagrange Multiplier LM Test	= 2.88e+05	P-Value > Chi2(58) 0.0000
- Likelihood Ratio LR Test	= 423.7543	P-Value > Chi2(58) 0.0000
- Wald Test	= 8.89e+07	P-Value > Chi2(59) 0.0000

4.6 Wooldridge test

Because serial correlation in linear panel-data models biases the standard errors and causes the results to be less efficient, researchers need to identify serial correlation in the idiosyncratic error term in a panel-data model. While some tests for serial correlation in panel-data models have been proposed, a new test discussed by Wooldridge (2002) is desirable because it requires relatively few assumptions and is easy to implement(Drukker, 2003). This article presents the results of a size and power simulation study of this new Wooldridge test. Because the test is flexible, simulations must be performed for some different cases. This paper presents results from simulations for both fixed and random-effects designs, with and without conditional homoscedasticity in the idiosyncratic error term, with balanced data, and with unbalanced data with and without gaps in the individual series. The power simulations include both autoregressive and moving-average alternatives. The test is found to have good size and power properties with samples of moderate size. The result of this test presents p-value 0.0000 which causes to reject H0(no first-order autocorrelation), so this hypothesis has an autocorrelation.

Table 7   Wooldridge Test for Model Two

Wooldridge test for autocorrelation in panel data		
H0: no first-order autocorrelation		
F(1,	58) =	0.556
Prob> F =	0.4589	

4.7 GLS test result

To find out the final model for each hypothesis the Cross-sectional time-series FGLS regression It has been applied in this study(Hoechle, 2007). In previous steps of diagnostic test, the Heteroskedacityand serial correlation in this step based on the result of the above tests, the final model has considered to fixed these issues. The following analysis presents the coefficient of independent, control and moderator variables on the target variable based on the current hypothesis.

Table 8   Cross-Sectional Time-Series FGLS Regression for Model Two

Cross-sectional time-series FGLS regression

5 Conclusion

By refer to the result of tests it has been found that the earning managements activities has negative effects on firm performance, but in second model whenever the corporate governance variables have played the role of moderating variables the effects of earning management activities have been covered and it has been changed to neutral. In conclusion this study has found that by applying the corporate governance strategies, it is possible to prevent managements to abusing the firm performance.

Abstract: Financial literacy is considered as one of the key indicators of entrepreneurial conduct. Understanding the role of financial literacy will empower the researchers to investigate the progression of entrepreneurial venture creation process. In the complicated and competitive business setting, financial literacy helped entrepreneurs through improving the skills to manage financial resources productively over the business life cycle while effectively connecting with financial products and services. However, determinants of performances of small and medium enterprises (SMEs) and the influence of financial resource availability on SMEs performances are limited in the literature. In this knowledge gap, the objective of this research paper is to propose a conceptual model to explain the impact of financial literacy and financial resource availability on the SMEs performances. Findings of this study revealed the positive relationship among financial literacy, financial resource availability and SMEs performances. Further, results show that the relationship between financial literacy and SMEs performances positively moderate by the financial resource availability. This article makes novel contribution to the existing literatured by bringing financial resource availability in the context of SMEs performances. Further, the model can be empirically tested in future research.
Key words: Entrepreneurship; Financial literacy; Financial resources; SMEs performances

1 Introduction

The emerging significance of financial literacy is well documented in recent literature. Financial literacy is vital for entrepreneurs to make financial decisions. It helps to empower and educate entrepreneurs on finance and to use that knowledge for evaluating and making decisions on financial issues in their businesses. Further, it is expected that financial literacy would help to deal with challenges in cutting edge credit markets.   Moreover, financial literacy enables entrepreneurs to manage risks through the strategies such as maintaining financial reserves, diversifying investment portfolio and buying insurance policies.

Xiao, Tang and Shim (2009) defined financial literacy as the knowledge on behaviors that are pertinent and applicable in financial management which deliberate the knowledge of income, money management, saving and investing, and spending and credit. Further, financial literary has been defined as the knowledge and cognitive capabilities entail to manage and to make effective decisions on finance such as budgeting, bookkeeping, bills and utilities payments, loan acquisition and payments and other financial decisions (Adomako, Danso, & Ofori Damoah, 2016). Accordingly, in this complicated and competitive business setting, financial literacy helps entrepreneurs through improving the skills to manage financial resources productively over the business life cycle while effectively connecting with financial products and services.

Small and Medium Enterprises (SMEs) plays a vital role in economic development through wealth distribution, creating employment, enhancing technological advancements, reducing poverty and increasing innovations (Arribas & Vila, 2007). Formation of SMEs is crucial for the establishment of a solid industrial base (Smallbone, Welter, Voytovich, & Egorov, 2010). Though SMEs are instrumentals in the economic development of developing countries that has enormous potential for the growth of this industry, it has not yet been able to fully realize its potentials. Inadequate financial literacy among entrepreneurs has been one of the main barriers for SMEs to realize its full potentials. Empirical studies reveal the existence of low level of financial literacy among entrepreneurs. Atkinson and Messy (2012) identified financial literacy as a common problem among SME owners and it affects to start and develop their businesses. Kim (2000) observed the lack of financial literacy among entrepreneurs as the major reason to increase the failure rate of SMEs.

Eniola, Entebang and Sakariyau (Eniola, Entebang and Sakariyau, 2015) defined resources as anything that create strengths and weaknesses for organizations in the form of tangible and intangible assets. As per the resource-based view (RBV), the assets that create sustainable competitive advantages for the organization can be identified as strategic resources. Further, RBV (Barney, 1991) proposed that

valuable, rare and inimitable resources as the sources of competitive advantage. According to RBV theorists, organizations should attempt to use existing resources effectively to get maximum advantages from external opportunities. Because of rapid changes in financial landscape, availability of financial resources remains as a fascinating issue in both developed and developing economies. Financial resources are essential to start, operate and growth of a business (Bygrave & Zacharakis, 2008). SMEs tend to experience difficulties in accessing finance to facilitate business operations. Thus, finance is an important but scarce resource for SMEs and it is important to manage available financial resources efficiently and effectively.

This study was designed by considering the importance of financial literacy in SMEs context, and aiming at the prevailing research gaps on financial literacy and SMEs performances. Further, this research adopts the RBV theories to describe the importance of financial resource availability in SMEs context. The main research question in this study is: How does financial literacy and financial resource availability impact on SME performances? Further, this study aims to contribute the entrepreneurship literature by investigating the moderating effect of financial resource availability to the relationship between financial literacy and SMEs performance.

2 Literature Review and Hypotheses

Various theoretical perspectives such as exchange theory, transaction cost theory, prospect theory and resource-based theories tried to establish the relationship between financial literacy and performances of the organizations. According to exchange theory higher interaction among interpersonal, interactional, procedural and informational factors cause to improve the literacy level of the individuals. Transaction cost theory explains the influence of transaction cost to the performances. Accordingly, financial literacy enables entrepreneurs to identify profitable transactions which improve the organizational performances. According to prospect theory, financial literacy improves the decision-making capacity of entrepreneurs and hence enhances the organizational performances. Resource based theories explained organizational resources and capabilities as the prominent determinants of organizational performances and the necessity of higher level of financial literacy to use those assets in order to improve the organizational performances.

The impact of financial literacy on firm performances rigorously studied in the literature and revealed the positive relationship among them (Huston, 2010). Further, the importance of effective financial management for SMEs performance and success is also highlighted in the literature (Fatoki, 2014). Wise (Wise, 2013) revealed the importance of financial literacy for the survival of SMEs in both developed and developing countries. Low level of financial literacy caused to poor financial management practices and to commit frequent financial mistakes (Lusardi, 2012). Moreover, Huston (Huston, 2010) pointed out the importance of financial literacy to cope with rapid economic changes. Thus, financial literacy is conceived to positively effect to the SMEs performance. Accordingly, first hypothesis of this study is developed as follows.

H1: Financial literacy positively effects to the SMEs performance.

Financial resources can be defined as funds receive from the family in business, network relations, and financial institutions like banks or as equity (Coleman, 2007). Further, these sources can be categorized as internal and external financial sources. However, it is difficult for SMEs to acquire all required funds from internal sources. Thus, they often seek for external financial sources which are difficult to access for most SMEs. Researchers have identified lack of financial resources as the major obstacle for the SMEs development (Ihua, 2009). Higher interest rate charged by bankers and unavailability or incomplete financial statements, insufficient collaterals and SMEs managerial skills constrained the financial resource availability for SMEs (Bosri, 2016).

Financial literacy level of SME owners' affects to business performances as it helps them to manage financial issues effectively (Siekei, Wagoki, & Kalio, 2013). However, mere financial literacy of entrepreneurs is not sufficient to SMEs performances as financial resources are essential to operate businesses (Danso & Adomako, 2014). Chowdhury, Alam and Arif (2013) observed insufficient financial resources affects to acquisition of fixed assets and to business operations while hindering SMEs performances. Further, inadequate financial resources limit the innovations and competitiveness in the market. In contrast, organizations rich with financial resources can easily obtain loan facilities from financial institutions by fulfilling collateral requirements. Financial resource availability is, therefore, vital for the SMEs performances. Thus, financial resource availability strengthens the relationship between financial literacy and SMEs performance. Accordingly, relationship between

financial literacy and SMEs performances is expected to be positively moderate through financial resource availability. Consequently, the second and third hypotheses of this study can be stated as follows.

H2: Financial resource availability positively effects to the SMEs performance.

H3: Financial resource availability positively moderates the relationship between financial literacy and SMEs performances.
Figure 1   Conceptual Model

3 Methodology

The population of this study was comprised with Small and Medium Scale Enterprises (SMEs) in Sri Lanka. However, 150 SMEs owner managers were selected from the western province using the convenient sampling technique to conduct this study. Western province was selected as it comprises with the highest number of SMEs compared to other provinces. Structured questionnaires were used to collect data and it was comprised with four main sections; Section 1- Demographic factors, Section 2- Financial literacy, Section3- Financial resource availability and Section 4- SMEs Performances. Further, firm size and age used as controllable variables as both variables have an impact on firms' performances. The descriptive statistics and tabulation techniques were used to describe the results. Further, three hierarchical multiple regressions were used to achieve research objectives. Table 1 illustrates the constructs of the questionnaire.

Table 1   Constructs of the Questionnaire

Content	No. of Items	Source
Financial literacy	4	Dahmen and Rodr ǵuez (2014)
Financial resource availability	5	Shepherd and Wiklund (2005)
SMEs performances	6	Kropp, Lindsay and Shoham (2006)

4 Analysis and Discussion

A total of 150 completed questionnaires by SMEs owner managers were subjected to analysis. Majority of the sample (72%) is comprised with male entrepreneurs. Age distribution of the sample includes five age categories and the highest number of entrepreneurs is represented by 40 – 49 years age group and as a percentage it was 39 percent. Furthermore, most of the entrepreneurs had completed education up to GCE Advanced Level (42 %). The outcome of the research further showed that 30 percent of entrepreneurs have diplomas and 17 percent of entrepreneurs belong to the category of graduates. Also, 54 percent of the sample had no previous experience before starting their business, and 68 percent of the respondents had a family with an entrepreneurial background.

Table 2   Correlation Matrix

	Mean	SD	FL	LA	LS	FRA	FP
Financial literacy (FL)	2.431	0.231	1				
Log age (LA)	0.532	0.412	0.396**	1			
Log size (LS)	0.491	0.296	0.381**	0.219*	1		
Financial resource availability (FRA)	1.711	1.235	0.614*	0.214**	0.316**	1	
SME performances (FP)	2.683	0.961	0.612**	0.312	0.296**	0.813*	1

Note: The symbols (**) and (*) indicates the statistical significance at 99% and 95% level respectively.

Table 2 portrays the descriptive statistics and correlation matrix of financial literacy, firm's age,

size, financial resource availability and SME performance. Accordingly, the mean value of FL is 2.431 and it shows the low level of financial literacy among SMEs. It denotes that the most of these SMEs are not maintaining financial records thus creating barriers to access into financial resources as most of banks and financial institutes heavily rely on the quality of financial records when lending for SMEs. The mean value of 1.711 depict that the average SMEs have low financial resource availability. This causes to create survival and growth-related issues for SMEs while hindering the economic contribution of this sector. Moreover, financial resource availability positively correlated with FL, LA and LS while SMEs performances positively correlated with FL, LS and FRA. These findings congruent with the literature (Ngek, 2016) and it further supports to the positive correlation between SME performances and financial literacy.

Table 3   Results of the Moderating Effect of Financial Resource Availability

Factors	Model 1		Model 2		Model 3	
	Beta	T value	Beta	T value	Beta	T value
Constant		13.23**		15.38**		11.31**
Log age	-0.04	-0.34	-0.04	-0.41	-0.7	-0.95
Log size	0.23	1.53	0.03	0.73	0.01	0.36
Financial literacy (FL)	0.41	6.71**	0.23	2.51**	0.41	4.32**
Financial resource availability (FRA)			0.59	10.37**	0.97	9.83**
FL x FRA					0.53	4.76**
R^2	0.27		0.57		0.64	
Adjusted R^2	0.29		0.54		0.61	
F value	26.57**		56.72**		54.74*	
R^2 change			0.30		0.07	
F change			85.42**		25.89*	

Note: The symbols (**) and (*) indicates the statistical significance at 99% and 95% level respectively.

To test the hypothesis that the higher financial literacy and financial resource availability increase the SMEs performances, and more specifically whether financial resource availability moderate the relationship between financial literacy and SMEs performances, a hierarchical multiple regression analysis was conducted. The result of the moderating effect of financial resource availability is depicted in table 3. In model 1, firm age, size and financial literacy were included. These variables accounted for a significant amount of variance in SMEs Performances, R^2= .27, F= 26.57, p < .001. Further, it was observed the positive relationship between financial literacy and firm performances. Results are accordance with the previous studies (Huston, 2010; Lusardi, Mitchell, & Curto, 2010). Thus, the first hypothesis of the study was accepted.

In the model 2, moderating variable (financial resource availability) was included and results were accounted for a significant amount of variance in SMEs performances, R^2= .57, F= 56.72, p < .001. Addition of financial resource availability variable significantly affected to the model while increasing the predicting power of the model (R^2 change= .30, F change= 85.42, p< .001). Further, results revealed the positive relationship between financial resource availability and SMEs performances. Hence, second hypothesis also accepted. Moreover, results imply the significance of SMEs accessibility to financial resources in order to increase the firm performances.

In the model 3, interaction variable (FL x FRA) was included into the model. The probability of F value showed that the overall model is significant (R^2= .64, F= 54.74, p < .05), and hence suitable for predict SMEs performances. Further, addition of interaction variable to the model significantly increases the predictability of the model (F change= 25.89). However, variation explained by the model is increased only by 7 percent. These results showed that the financial resource availability positively moderate the relationship between financial literacy and SMEs performances. Accordingly, third hypothesis was accepted.

5 Conclusion

The aim of this study was to explain the appropriateness of financial literacy and financial resource availability in understanding SMEs performances. Firstly, it showed the direct relationship between financial literacy, financial resource availability and SMEs performances. Secondly, it showed financial resource availability as the moderator in the relationship between financial literacy and SMEs performances. This research has implications for both future research and practice. The identified positive influence of financial literacy on SMEs performances is further highlighted the importance of the

financial literacy. However, financial literacy has not been widely recognized in developing economies as one of the key competencies that could significantly enhance SMEs performances. From theoretical perspective, there is a need for researchers in developing economies to examine the relationship between financial literacy and SMEs performances. Also, the concept of financial literacy is still in the early stage of investigations. As a result, there is no valid measurement scale in order to measure the concept of financial literacy. Thus, future research needs to develop a valid and reliable measurement scale to measure financial literacy. From a managerial perspective, the findings in this study suggest the need for policy makers in Sri Lanka and other developing economies to more emphasis on improving financial literacy skills of entrepreneurs. Further, policies should be introduced to solve financial accessibility barriers of the entrepreneurs. Moreover, while the direct effect of financial literacy on SMEs performances is very important, this study indicates that financial literacy should not be treated in isolation when examining aspects of SMEs Performances.

Abstract: Strategic orientations like Market orientation (MO) and Learning orientation (LO) play critical role in improving the performance of both large and small scale businesses. This paper investigate the relationship between LO and organizational performance with MO as moderator. The current study reports the findings of two hundred and seven owners or managers of Small and Medium Sized Enterprises (SMEs) in Pakistan. The findings of the study indicate a positive relationship between LO and organizational performance. Mo was found to have moderated the direct relationship between LO and organizational performance. This study is among the few attempts made to systematically examine the interplay among MO, LO and organizational performance in SMEs operating in Pakistan.
Key words: Strategic orientation; Pakistan; Organizational performance; learning orientation; Market orientation

1 Introduction

Enhancing the productivity and competitiveness of the organizations has been an issue for both small and large organizations around the globe. In this context, organizations needs to deliver products with superior value in order to meet the changing needs and expectations of the customers (Beneke, Blampied, Dewar, Soriano, & Deacon, 2016). Prior studies in the strategy literature have suggested that business organizations must adopt those strategies that help them to effectively respond to the changing market demands (Hilman & Kaliappen, 2014), and compete successfully in the dynamic business environment (Altinay, Madanoglu, De Vita, Arasli, & Ekinci, 2016; Jogaratnam, 2017). Research scholars have highlighted that both small and large organizations need to deploy strategic orientations (e.g. MO and LO) in order to survive and grow in the competitive business environment (Jabeen & Mahmood, 2015).

Prior studies focusing on strategic orientation have suggested that the adoption and implementation of two strategic orientations namely Market orientation (MO) and learning orientation (LO) help both small and large organizations to enhance their core competitiveness, satisfy the current and latent needs of the customers and achieve improved organizational performance (Choi, 2014; Lin, Peng, & Kao, 2008; Mokoena & Dhurup, 2016). MO reflects the organizational behavior to understand the changing buying pattern of present and potential customer as well as keeping vigilant eye on the competitors' move in the marketplace to deliver superior value to customers (Narver & Slater, 1990). LO on the other hand reflects an organization ability to generate and share the market related information across the organization and facilitates the superior value creation (Sinkula, Baker, & Noordewier, 1997). Review of the extant literature in the subject area has highlighted that the complimentary effects of both MO and LO enable the organizations to respond effectively to changing market demands, gain competitive advantage and enhance the organizational performance (Slater & Narver, 1995).

Notably, the strategy literature has highlighted that most of the prior researches have attempted to associate organizational performance with a single orientation, like LO and MO (Frank, Kessler, Mitterer, & Weismeier-Sammer, 2012; Hilman & Kaliappen, 2014). However, recently researches argue that the adoption and implementation of a single orientation may prove less effective to achieve improved organizational performance (Baker & Sinkula, 2009; Hakala, 2011), and suggested that organizations need to build their strategies based on multiple orientations together in order to survive and grow in today's challenging business environment (Laukkanen, Nagy, Hirvonen, Reijonen, & Pasanen, 2013). Prior researches argued that organizations that deploy multiple strategic orientations are in better position to respond effectively to the changes posed by business environment and exploit the business opportunities (Choi, 2014; Deutscher, Zapkau, Schwens, Baum, & Kabst, 2016; Farrell & Oczkowski, 2002). In the light of the aforementioned arguments, the present study takes an integrated approach and investigates that how MO and LO together influence that organizational performance of

SMEs.

Nevertheless, majority of the studies on strategic orientations have been conducted in developed economies and in large organizational settings. However, prior studies argue the researchers should not assume the interplay between strategic orientation and performance as homogenous in all contexts due to low sampling variance and suggested the inclusion of moderator in the relationship according to the context of the study (Rauch, Wiklund, Lumpkin, & Frese, 2009). The researchers more recently called for further attention to investigate the interplay between LO and MO in developing countries like Pakistan (Hussain, Rahman, & Shah, 2016), the research area which has been paid less attention by the research scholars.

The present study fills the gap in the literature by taking a configuration approach to examine that whether MO moderates the LO-organizational Performance link in the context of SMEs operating in Pakistan. We suggest that firms can achieve improved organizational performance by deploying effectively their strategic orientations like LO and MO simultaneously.

2 Literature Review

2.1 Learning orientation

LO of an organization demonstrate its ability to develop a mechanism where market related knowledge is created and shared among the members across the organization for attaining the competitive advantage and superior performance (Calisir, Gumussoy, & Guzelsoy, 2013). This mechanism include observing changes in the market, intelligence generation and sharing regarding preferences and taste of the customers, keeping a vigilant eye on competitors actions and developing/ and adopting new technologies to exploit the business opportunities in those markets where the competitors have not yet reached (Sikora, Nybakk, & Panwar, 2016). A learning oriented organization is capable to generate and utilize market related information by exhibiting strong commitment to learn with in and out the organization, open mindedness in questionaing and challenging its current ways of doing things and developing new ways to learn about its customers and competitors to deliver superior customer value (Kaya & Patton, 2011; Sinkula, et al., 1997). Shared vision demonstrates the value   an organization gives to the learning process (Calantone, Cavusgil, & Zhao, 2002), to transform the organizational learning acquired into action by its members (Calisir, et al., 2013; Sinkula, et al., 1997). Concentrating on these dimensions of LO enable organizations to be sensitive to market changes, generate market related information and respond to the changing market demands effectively that ultimately results in gaining competitive advantage and greater performance.

2.2 Market orientation

MO reflects the ability of a firm to create superior customer value by displaying its strong commitment towards delivering superior customer value, satisfying its customer, maintaining long term customer relationships, sharing and responding to competitors related information and exploiting the business opportunities based on market related information (Attia, 2013; Slater & Narver, 2000). Narver and Slater (Narver and Slater, 1990) conceptualised MO as a three dimensions   construct explaining the machanism under which a firm understand its target customers (customer orientation), observe movement of its competitors and discussing their strategies (competitor orientation) and sharing these information across the organization (interfunctional coordination) getting input from them, devising strategies and delivering superior value to its customers. Market oriented organizations are in better position to identify needs and wants of the customers and get closer to them to fulfill them   which ultimately results in creating and deleievering better customer value enabling organizations to be on more competitive position (Baker & Sinkula, 2009; Hilman & Kaliappen, 2014).

2.3 Learning orientation and organizational performance

Review of the previous literature on strategic orientation has highlighted that LO facilitates   and enables both large and small businesses to acquire and develop knowledge by understanding the changing needs of the market and thereby fulfilling the needs of the customers (Hakala, 2013; Maes & Sels, 2014). Prior studies have reported the significant influence of LO on organizational performance. For example, a study conducted by Calantone et al. (Calantone et al., 2002) reported a significant and positive impact on organizational performance. These researchers further reported that LO has indirect influence on organizational performance through competitive advantage. A recent study conducted by Rhee, Park & Lee (Rhee, Park & Lee, 2010) in small technology innovative firms in South Korea opined that an organization that simultaneously deploys both strategic orientations (MO & LO) would be in a better position to improve its overall performance. They further added that focusing LO strategy

more compare to MO can enable an organization to bring innovation and will results in greater competitive advantage. A more recent study conducted by Maes and Sels (Maes and Sels, 2014) support the notion that the implementation of LO strategy with other strategies can facilitate the organization in attainment of its predetermined goals. More recently, Kharabsheh, Ensour, &Bogolybov(Kharabsheh, Ensour, & Bogolybov, 2017) conducted their study on 190 senior managers working in manufacturing organizations in Jordan and concluded that LO helps organizations in improving their organizational performance. Hence, on the basis of the extant literature, the following is predicted.

H1: Learning orientation is positively associated with the organizational performance of SMEs in Pakistan.

2.4 Moderation by market orientation

Prior studies in strategic management have reported that MO facilitates nurturing of LO in organizations because of its responsiveness to the external environment in terms of learning from outside the organization (Slater and Narver, 1995; Fang et al., 2014). The same view is supported by Matsuno, Mentzer, &Ozsomer(2002) that high market orientation of an organization leads to its high LO. Moreover, Dickson (1996) argues that LO provides a fertile environment to all other strategic orientations in an organization for the reason that of its ability to constantly enhance the market information generation process. Other studies suggested that an organization must deploy MO and LO together for improved organizational performance (Baker & Sinkula, 2002; Dada & Fogg, 2016). In the same line, a more recent study by Deutscher et al. (Deutscher et al., 2016) argue that implementation of both high level of LO and MO together results in greater organizational performance.

Notably, the few existing studies that consider both MO and LO simultaneously investigated 1) the direct effects of these orientations on performance (Baker & Sinkula, 1999; Santos-Vijande, Sanzo-Perez, Alvarez-Gonzalez, & Vazquez-Casielles, 2005), 2) investigated the mediating role of LO (Keskin, 2006; Yeni, Hastini, & Hasti, 2017), or moderating effect of LO (Beneke, et al., 2016; Fang, Chang, Ou, & Chou, 2014) on the relationship of MO and performance. Moreover, majority of these studies have been conducted in large organization settings in developed countries. Nevertheless, scholars argue that the results obtained from large organization may not be applicable to small organization because SMEs use small portion of marketing research and encounter greater financial pressure(Lonial & Carter, 2015). Moreover, SMEs in developing countries operate in poor state of infrastructure, having limited access to finance and underdeveloped institutional environment as compared to large organizations (Roxas, Ashill, & Chadee, 2016; Zayed & Alawad, 2017). Therefore, this study attempts to address the gaps in the strategy literature and investigate the possible moderating effects of MO on LO and organizational performance relationship in the context of SMEs operating in a developing country like Pakistan. Hence, we hypothesized the following.

H2: Market orientation moderates the association between learning orientation and organizational performance of SMEs in Pakistan.

3 Research Methods

3.1 Study context and sample

The context of the current study is Pakistan. SMEs play a critical role in promoting the economic growth, raising standard of living and improving the industrial development of both the developed and developing countries (Dar, Ahmed, & Raziq, 2017). In developing economies SMEs contribute positively to the creation of employment opportunities, reduction in poverty, development of entrepreneurship (Hosseininia & Ramezani, 2016).SME sector in Pakistan contributes 30% to Gross Domestic Products (GDP), though this sector constitutes 93% of the overall businesses in Pakistan (Mirani & Shah, 2012). The challenges these SMEs face include; lack of education and training, difficulty in access to finance and modern technology and, entrepreneurial skills which may have somehow negative impacts on health of these SMEs (Hussain, Abbas, & Khan, 2017; Jaffari et al., 2011). Though, the respective share of this sector into national economy is low compared to the large organizations, however, the importance of this sector cannot be ignored in the economic and social development process of the country. It is argued that the development of this sector is one of the prerequisites for ensuring economic and social development in any country (Dobrovic, Lambovska, Gallo, & Timkova, 2018) . Keeping in view the increasing importance of this sector, the current study highlights the important role these strategic orientations can play in development of this sector and making it more competitive, since this sector has the potential to promote social and economic development.

The data were collected from owners or managers of SMEs registered with either SMEDA or chamber of commerce, with less than 250 employees as per the criteria of Small and Medium Enterprises Authority (SMEDA) Pakistan for definition of SMEs. This study concentrated on two big cities of Pakistan namely Islamabad and Peshawar for data collection. For this purpose, 400 questionnaires were randomly distributed among the respondents, of which 225 were received back, of which some were discarded due to missing information. The usable responses were calculated to be 207, resulted in a response rate of 52%.

3.2 Measurement

This study used quantitative research methodology to collect the primary data. MO was measured through 15-items scale, adapted from Narver& Slater (Narver& Slater, 1990). LO was measured through 15-items scale adapted from Sinkula et al. (Sinkula et al.,1997) and validated by Nasution et al. (Nasution et al., 2011). MO and LO were measured on five-point Likert scales, ranging from 1 = "strongly disagree" to 5 = "strongly agree". The organisational performance as dependent variable was subjectively measured through 3- items namely market share, sales growth and overall performance on a five-point Likert scale ranging from 1 = "poor" to 5 = "excellent", where the by asking the respondent. The respondents were asked to assess the results of their companies against the competitors over the past three years.

3.3 Data analysis

To ascertain the reliability, pilot testing of the developed instrument was performed. The Cronbach alpha reliability statistics were used to measure the reliability of the variables of the study. The alpha reliability for MO and LO and organizational performance was checked and found to be 0.68 and 0.68 respectively. The alpha reliability results for the dimensions of MO and LO are as follows; competitor orientation (0.67), customer orientation (0.70), inter-functional coordination (0.66), commitment to learning (0.80), shared vision (0.79) and open mindedness (0.77). The alpha values of the main variable and their sub-dimensions were found to be above 0.60 (Hair, Babin, Money, & Samouel, 2003), and thus indicated that the instrument is reliable. Descriptive statistics i.e. skewness and kurtosis were used as indicators of the deviation which have been suggested by Meyer, Becker, & Van Dick (2006) to confirm that whether the data is normal. The values derived for both skewness and kurtosis were within acceptable range indicating the data was normal. Inferential statistics were used to test the hypotheses of the study. Pearson correlation was used to confirm the correlation among the variables of the study. Linear regression analysis was conducted to check the significant influences of LO on organizational performance. The moderating effect of MO on LO-organizational performance link was also checked using Baron and Kenny (Baron and Kenny, 1986) approach. Other assumptions like homoscedasticity, multicollinearity were satisfied before the regression analysis was performed.

4 Findings

The results of linear regression analysis derived from testing H1 are given in Table 1. The results indicated that LO has a significant (F=155.006, p=0.000) and positive impact on organizational performance (standardized β = .656). Therefore, H1 of the study is supported.

Table 1   Coefficients for H1

Hypothesis	Mean	Standardized beta	F	Sig
H1	Learning Orientation	0.656	155.066	0.000

Note: Dependent variable: organizational performance

The results of moderating effects of MO on LO and OP relationship using three steps Baron and Kenny (1986) method of moderation are reported in Table 2. The results of linear regression have already been reported in Table 1, where LO has significant and positive impact on organizational performance (Step 1). In step 2 of the Table 2, MO was added as moderator with LO. The results indicated that the addition of MO showed the increase of 02 per cent R-square i.e. 0.433-0.431=0.355 (change of F-value= 81.198, p <0.05). In step 3 of Table 2, after adding the interaction term of MO and LO (LO*MO) with step 2, the explanation power of the model increased to 77.1 per cent (R^2 = 0.771; p <0.001). The results reported that interaction term resulted in significant increase of 33.8 in explaining the variance in OP (change in F-value = 227.713, p <0.001). The results demonstrate that adoption and implementation of high level of MO practices in organizations strengthen the LO-OP relationship. Thus, hypothesis H2 is supported.

Table 2   Model Coefficients and Summary for H2

Step		Standardized beta	R	R^2	F Change	Sig. F Change
1	LO	0.656	0.656	0.431	155.066	0.000
2	LO	0.617	0.666	0.433	81.198	0.000
	MO	0.119				
3	LO	-.594	0.878	0.771	227.713	0.000
	MO	-.118				
	IT	1.424				

* LO (Learning orientation), MO (Market orientation), IT (Interaction Term).
Note: Dependent variable: Organizational Performance

5 Discussion

The objective of the present study was to investigate the role of LO and MO for improving organizational performance of SMEs in Pakistan. The current study also examined the moderating effect of MO on organizational performance. To examine how LO strategy is critical for improving the organizational performance; we tested our first hypothesis (H1) to check the effects of LO on organizational performance. The results demonstrated that there is positive and significant influence of LO on organizational performance and support the previous studies indicating that LO positively influence firm performance (Keskin, 2006; Wang, 2008). To examine the moderating effect of MO on the LO-organizational performance relationship, we tested our second hypothesis (H2), the results of which revealed that MO moderates the link between LO and organizational performance. The results support the work of Baker and Sinkula (Baker and Sinkula, 1999) that both MO and LO enable organizations to deliver superior customer value and leverage the market opportunities by serving with innovative products. Voola, Casimir, Carlson, &Anushree(Voola, Casimir, Carlson, & Anushree, 2012) also support the notion that organizations deploying multiple orientation simultaneously are better able to serve the customers and compete in the dynamic market successfully.

6 Conclusion

This research has several limitations. Subjective performance measures were used in light of the previous studies of Narver and Slater (Narver and Slater 1990) and Roxas et al. (Roxas et al., 2016). However, objective performance measures such as financial data would be valuable to be employed and the results should be compared with the current study for more insights on the subject matter. Moreover, this study relied on subjective performance measures, so on the survey design of the current study. This study provided an integrated approach and investigated the relationship between MO, LO and organizational performance, it is proposed that future research may take the sub dimensions of these orientations and their relationships with organizational performance may be examined. This study was conducted in SMEs operating in two cities of Pakistan; future studies concentrating on other industrial hubs of the country are proposed to be conducted for gaining more insights on the behaviour of these orientations.

Entrepreneurial Leadership and Innovation: The Mediating Role of Employee Voice Behavior

Farhan Aslam, Qamaruddin Maitlo
School of Management, Wuhan University of Technology, Wuhan, P.R. China, 430070
(Email: aslam.farhan@outlook.com, farhan@whut.edu.cn, qamarmaitlo@yahoo.com)

Abstract: This study uses a systematic quantitative research approach to identify the relationship between entrepreneurial leadership (EL) and innovation through the moderating effect of employee voice behavior (EVB). This study focuses on employees of Pakistani medium and large enterprises and implies that there is a positive and significant relation between EL and innovation and similarly between EL and EVB. Current study concludes that EVB also partially mediate the relationship between EL and innovation, which means that there are other factors mediating their relationship about which further research needs to be done. It can be concluded from this paper that the firms having entrepreneurial leadership ability in their employees and having EVB in organizational culture are usually good at innovation.
Key words: Entrepreneurial leadership; Employee voice behavior; Innovation; Organizational culture

1 Introduction

Over the past couple of decades, the business environment has changed dramatically due to rapid globalization and technological advancements. The only way of survival for businesses is innovation, which is now regarded as the key success factor and pinnacle for growth and survival in the modern business era (Rajapathirana & Hui, 2017). Recent developments in the theory of economic growth have highlighted the importance of innovation for sustainability in output and growth in productivity for firms specifically in developing countries (Wadho & Chaudhry, 2018). A number of studies have reported a positive relationship between innovation and labour productivity, profitability, firm growth, openness, and other firm-level outcomes (Wadho & Chaudhry, 2018). Innovation has been defined in a number of ways, one important definition is that Innovation is an outcome, process and mindset at the same time, which facilitates an organization to search and get maximum out of opportunities (Kahn, 2018). An important feature of innovation is that it should be implemented (EUROSTAT/OECD, 2005).

Firm's innovational ability is affected by many factors, and one main factor that influences innovation is leadership. The 21st century is especially focusing on a new type of leadership i.e. entrepreneurial leadership (Mishra & Misra, 2017). To innovate regularly, the firm must internalize entrepreneurial behaviors and attitudes that increase innovativeness ability of the firm (Avanti Fontana, 2017).

This study focuses on studying the relationship between EL and innovation through mediating effect of EVB which is believed to have a strong relationship with entrepreneurial leadership and innovation (Chen & Hou, 2016). This study is done focusing Pakistan medium and large enterprises who are struggling to compete with the multinational firms despite having financial and other resources (Aslam, Zulqarnain, Shoaib, & Akram, 2014).

The systematic quantitative approach is used in this study. Questionnaires from previous studies were selected and modified for the present study. Data was collected from the top and middle-level managerial employees of Medium and large-scale Pakistani enterprises both from manufacturing and service sector.

This study is significant in several ways; first, it has deliberated innovation from a different perspective i.e. from a perspective of entrepreneurial leadership. Secondly, EVB has been introduced as a moderator in the relationship between EL and innovation. EVB is a behavior if managed carefully can contribute significantly in encouraging both EL and innovation. Thirdly, this study has opened new directions for future research in the area of leadership, innovation, and employee behavior. Lastly, this study was done focusing Pakistani medium and large-scale enterprises, who are facing severe problems to complete in the era of globalization and technological advancement, and for them, innovation in the only option for survival. This study has provided some useful learning for managers of Pakistani firms on how they can improve their innovative capability and competitiveness by focusing on EL and encouraging EVB.

2 Literature Review

Term innovation has always attracted lots of attention from researchers in the management field; however, still, there is a lot of debate about the true definition of the term. This confusion about the definition of term innovation is created by the difference of opinion available in the literature. It should be noted that innovation is combination of three different things i.e. (1) innovation is an outcome, which encompasses what is sought by the innovation like product innovation, process innovation, business model innovation and market innovation, (2) innovation is continuous process and lastly (3) innovation is a mindset which tries to internalize the innovation in the individuals of the organization (Kahn, 2018). A more commonly used definition of innovation by business sector is provided by paragraphs 146 and 150 of Oslo Manual (Guidelines for Collecting and Interpreting Innovation Data) also cited by (Gault, 2018), which states that "An innovation is the implementation of a new or significantly improved product (good or service), or process, a new marketing method, or a new organizational method in business practices, workplace organization or external relations". According to Oslo Manual, another important feature of innovation is implementation i.e. "A common feature of an innovation is that it must have been implemented (EUROSTAT/OECD, 2005).

As the business environment is becoming increasingly competitive, leadership is gaining importance, especially where risks are increasing, forecasting becoming difficult, industries are converging (Bettis, 1995). To cope with the challenges of modern-day business environment the 21st century has shifted its focus on EL to cope with the challenges posed by rapid globalization and innovation (Mishra & Misra, 2017). EL is a combination of entrepreneurial orientation, entrepreneurship, leadership abilities and entrepreneurial management and could be defined as a process which brings together unique innovation and complete package of resources to reap the organizational opportunities (Avanti Fontana, 2017).

More recently, it has been identified that entrepreneurial leadership influence employees innovative work behavior that ultimately influences organizational innovation. (Newman, Tse, Schwarz, & Nielsen, 2018). Entrepreneurial leadership has a dual character, one as an entrepreneurial accelerator and other is entrepreneurial doers (Newman et al., 2018).

EVB is a constructive behavior which is defined as a challenge-oriented behavior directed towards the improvement of the situation.(LePine & Van Dyne, 1998). It is considered that voice behavior has a strong influence on the creativity and innovativeness of the employees (Chen & Hou, 2016).

3 Research Framework

Based on the literature review and gaps identified, following research framework is developed for the current study (Figure 1).
Figure 1   Research Framework

3.1 Hypothesis development

Following hypothesis are formed based on the research framework, **H1:** Entrepreneurial Leadership positively influences innovation. **H2:** Entrepreneurial Leadership (EL) positively influence employee voice behavior. **H3:** Employee Voice behavior positively influences innovation. **H4:** Employee voice behavior mediates the relationship between EL and innovation.

4 Methodology

4.1 Participants and procedure

Data were collected from middle and senior level employees of medium and large-scale Pakistani enterprises from both manufacturing and service sector on a cross-sectional timeframe through convenience sampling technique using both faces to face and online survey methods. Convenience sampling technique was used keeping in view the availability of respondents, as all of them are busy professionals. 350 Questionnaire were sent, out of which 310 were got back, out of them, 22 were

discarded due to missing data and other problems and 288 questionnaires were included in final analysis which yields 82% response rate. Total 36 medium and large-scale organizations from six major cities of Pakistan Lahore, Karachi, Islamabad, Rawalpindi, Faisalabad, and Gujranwala participated ipn the study. 53% of organizations participated in this study are from the service sector and 47% are from the manufacturing sector. Demographic analysis of the respondents reveals that majority (74.3%) of the respondents are males, which shows males dominancy in professional sector of Pakistan. As far as Age distribution of respondents are concerned, 13.2% belongs to age bracket of 25~30, 13.9% ranges between 31~35 and 17.4% of the respondents fall within the age of 36~40, 17% to 41~45, 20% to 45~50 and 18.4 % to 50 and more respectively, which depicts that data set is relatively evenly distributed as far as age is concerned. 51 % of the respondents hold master's degree (16 years of education), 16% are undergraduate, and 28.8% holds graduation (12 years of education). Only 12 (4.2%) hold MPhil (18 years of education) and only one respondent (0.3%) holds PhD Degree. Respondents are also relatively evenly distributed as far as the number of years of experience is concerned, 16% of the respondents have 1~5 years of professional experience, 21% falls within the 6~10-year category, 18% within 11~15, 20% within 16~20 and 24% within 21 and more year's category respectively.

4.2 Measure used

To ensure the reliability and content validity, this study has adopted measures from previous studies.

4.2.1 Entrepreneurial Leadership

The measure for Entrepreneurial Leadership is adopted from (Avanti Fontana, 2017) which consist of 4 dimensions namely (1) Strategic Dimension having 10 items (2) Communicative dimension having 5 items (3) Motivational Dimension having 5 items (4) Personal / Organizational Dimension having 4 items. All items are measured on 5 points Likert scale (1 = strongly disagree and 5 = strongly agree). Reliability was assessed according to the guidelines of (Hair, Black, Babin, & Anderson, 2010). Cronbach's Alpha for Entrepreneurial Leadership is (α = .918).

4.2.2 Employee Voice Behavior

An instrument for employee voice behavior is adopted from (LePine & Van Dyne, 1998) which consist of 6 items. All items are measured on 5 points Likert scale 1 = strongly disagree and 5 = strongly agree) (Cronbach's α = .826)

4.2.3 Innovation

An instrument for outcome variable i.e. Innovation is adopted from INNOSCALE developed by (Vicente, Abrantes, & Teixeria, 2015) which consist of 13 items. It consists of four dimensions (1) product development capability having 4 items (2) innovativeness having 3 items (3) strategic capability having 3 items and (4) technological capability having 3 items e.g. All items are measured on 5 points Likert scale (1 = strongly disagree and 5 = strongly agree) (Cronbach's α = .724).

5 Hypothesis Testing

H1: Entrepreneurial Leadership positively influence innovation: A simple linear regression analysis was performed using SPSS version 23, taking Entrepreneurial leadership as independent variable and Innovation as an outcome or dependent variable.

Table 1   Regression Analysis Between EL (IV) and Innovation (DV)

F	Standardized Beta Coefficient	Sig (p)	Result
Model is Significant at (1,285)=20.253,p<0.01	.258	0.001	H1 is supported

H2: Entrepreneurial Leadership positively influences employee voice behavior. To test H2, again simple linear regression was performed taking entrepreneurial leadership as the independent variable and employee voice behavior as the dependent variable.

Table 2   Regression Analysis Between EL and EVB

F	Standardized Beta coefficient	Sig (p)	Result
Model is Significant at (1,285)=71.049,p<0.01	.447	0.001	H2 is supported

This result is in accordance with the finding of (Chen & Hou, 2016), who states that leaders are now concerned about their employees showing willingness and raising voice against organizational issues.

H3: Employee Voice behavior positively influences innovation. Simple linear regression analysis was performed to test the H3, taking employee voice behavior as independent variable and innovation as the dependent variable.

Table 3   Regression Analysis Between EVB and Innovation

F	Standardized Beta coefficient	Sig (p)	Result
Model is Significant at (1,286) =14.388, *p<0.01*	.219	0.001	H3 is supported

Results are in line with the finding of (Chen & Hou, 2016), who states that employee voice behavior has a strong and positive effect on creativity and innovativeness of the firm.

H4: Employee voice behavior mediates the relationship between EL and innovation.

Table 4   Mediation Analysis

	Model	Standardized Beta Coefficient	Sig (p)	Results
Direct (Without Mediator)	EL	.258	.001	
In-Direct (With Mediator)	EL Employee Voice	.201 .126	.002 .049	H4 is Partially supported

*Dependent Variable: Innovation

Analysis showed that both direct effect i.e. entrepreneurial leadership to innovation and indirect effect i.e. entrepreneurial leadership to innovation through employee voice behavior are significant, which implies that even though employee voice is mediating the relationship, however, there are some other factors that are also affecting the relationship between entrepreneurial leadership and innovation. Therefore, our findings support H4 partially. Further research needs to be done about the other factors that are affecting the relationship between entrepreneurial leadership and innovation.

6 Conclusion

In the current business environment, innovation is the key success factor for any business enterprise. With the rapid globalization and technological advancement, the enterprises who will not innovate on regular basis and will not keep pace with the changing trends of the market and business environment will soon perish. Following conclusions are drawn from the current study,

1.Entrepreneurial leadership has a strong and positive relationship with innovation, which means that firms having leaders (or managers) with entrepreneurial abilities in their cadre are more likely of better performing at innovation and vice versa.

2.Entrepreneurial leadership has a strong and positive relationship with employee voice behavior, which implies that employees will show voice that is behavior that is more constructive when they find entrepreneurial leadership guiding and supporting them and employees will raise more voice against problems within the organizational system that will ultimately increase their creativity and hence organizational innovation.

3.Employee voice behavior has a direct and positive relationship with innovation. It can be implied from this that if an employee raises their voices against problems in the organizational system and against status quo, then organizational innovation will improve.

4.Employee voice behavior also partially mediates the relationship between entrepreneurial leadership and firm's innovation, which implies that both direct effect (i.e. from entrepreneurial leadership to innovation) and indirect effect (from entrepreneurial leadership to innovation through employee voice behavior) are significant, which means that there are others factors who are influencing the relationship between entrepreneurial leadership and innovation which are not covered in this research and this require further research in this area.

Abstract: The SMEs are the main force of technological innovation, and strengthening the intellectual property management of the whole life cycle is the key measure to improve their innovation abilities. Based on the Life Cycle Theory and the main content in the different stages of IPR management on SMEs, this paperconstructs an evaluation index system covering five dimensions: Basic Resources, IPR Creation, IPR Application, IPR Protection, IPR Management. And then uses fuzzy composite evaluation to carry out an empirical analysis of taking the SF Company as an example. The evaluation results show that the current IPR process management of SF Company is in the "general" level (70.037), which is mainly affected by two factors: basic resources (66.612) and intellectual property management (67.833). Meanwhile, intellectual property creation (75.768), intellectual property application (70.961) and intellectual property protection (70.106) are all in the "general" level. So, four suggestions for improvement are put forward: independently set up the IPR management department, establish IPR management information system, strengthen the comprehensive monitoring of the key nodes of the enterprise R&D projects and expand the diversification of the IPR.
Key words: IPR process management; SMEs; Fuzzy comprehensive evaluation; Life Cycle Theory

1 Introduction

SMEs are the important force for technological innovation, creating 65% of China's invention patents and 80% of new products. In the new era of full implementation of innovation-driven development strategy, the state attaches great importance to the innovation capability of SMEs, especially the construction of IPR management ability, and has promulgated the regulations on enterprise intellectual property management (GB/T29490) for standardization and guidance. In recent years, the theoretical circle also pays close attention to the research of enterprise IPR management, such as, Porter (Porter, 1997),Stewart (Stewart, 1998),Wagman(Wagman, 1999),Foley (Foley, 2012) proposed that the establishment of IPR management system plays a significant role in enhancing the sustainable development capacity of enterprises. Wu Handong (Wu Handong, 2009), Du Yun (Du Yun, 2010), Philip (Philip, 2011) believed that the core of enterprise competitiveness lies in the IPR. Wang Yuxi (Wang Yuxi, 2008), Tang Heng (Tang Heng, 2010), GuoSiyong (GuoSiyong, 2013) proposed to integrate existing management activities to improve the efficiency of enterprise IPR management. However, different from the large and medium-sized enterprises, the practice of SMEs is still lack of theoretical support and practical demonstration, especially lack of how SMEs strengthening the management of intellectual property process in different life cycles. This paper will take SF Company as an example to carry out exploratory research on the process management of IPR in SMEs from the perspective of enterprise life cycle.

2 Evaluation System Construction

2.1 The establishment of evaluation index system

Based on Life Cycle Theory, the main content of IPR management in SMEs in different life cycle stages can be divided into five dimensionalities including the Basic Resources, IPR Creation, IPR Application, IPR Protection, IPR Management. Based on this, this paper designs the evaluation index system of IPR process management level as shown in table 1.

2.2 The establishment of fuzzy comprehensive evaluation model

1) Using the evaluation index system in Table 1, the factor sets are determined as $U= \{U_1, U_2, U_3, U_4, U_5\}$, the set of factors is: $U_1 = \{u_{11}, u_{12}, u_{13}, u_{14}\}$, $U_2 = \{u_{21}, u_{22}, u_{23}, u_{24}\}$, $U_3 = \{u_{31}, u_{32}, u_{33}, u_{34}\}$, $U_4 = \{u_{41}, u_{42}, u_{43}, U_{44}\}$, $U_5 = \{u_{51}, u_{52}, u_{53}, u_{54}\}$.

2) Setting up the evaluation set $V = \{v_1, v_2, v_3, v_4, v_5\}$. The five grades are: very good, good, general, poor, very poor, and the corresponding percentage points are 90-100, 80-90, 70-80, 60-70, and below 60.

3) A single factor evaluation is carried out. According to the raw data of SF Company for nearly three years, the proportion of each evaluation grade is calculated by the initial processing of data, and the fuzzy relation matrix R is established, as shown in Table 1.

4)The weight of indicators at all levels was obtained by using AHP, as shown in Table 1.

Table 1　The SMEs IPR Management Evaluation Index System

Grade I Indexes	Grade II Indexes	Fuzzy Evaluation Matrix R				
		V_1	V_2	V_3	V_4	V_5
Basic Resource U_1（0.23）	Institutional Settings for IPR Management u_{11}(0.324)	0	0	0.6	0.3	0.1
	Special Funds for IPR u_{12}(0.157)	0	0.1	0.7	0.2	0
	IPR Management Information Platform u_{13}(0.264)	0	0	0.2	0.7	0.1
	IPR Management System and the Work Plan u_{14}(0.255)	0.1	0.3	0.4	0.2	0
IPR Creation U_2（0.21）	Research Objectives and Strategies u_{21}(0.236)	0.1	0.1	0.6	0.1	0.1
	The Investment Intensity of R&D u_{22}(0.317)	0.3	0.2	0.5	0	0
	Number of R&D Personnel u_{23}(0.275)	0.2	0.4	0.4	0	0
	The Number of Patent Applications Growth Rate u_{24}(0.172)	0.2	0.3	0.4	0.1	0
IPR Application U_3（0.16）	The Application Rate of Patent u_{31}(0.313)	0.1	0.2	0.5	0.1	0.1
	Contribution Rate of IPR for New Profit u_{32}(0.209)	0.2	0.2	0.3	0.3	0
	The Use of Standardized Procedure u_{33}(0.187)	0	0.1	0.6	0.2	0.1
	The Effectiveness of the Competition Strategy u_{34}(0.291)	0.1	0.3	0.3	0.3	0
IPR Protection U_4（0.14）	Awareness and Ability of Rights Protection u_{41}(0.184)	0	0.3	0.4	0.2	0.1
	the Rate of Criminal Cases Registered of Annual IPR Disputes u_{42}(0.295)	0	0.3	0.5	0.2	0
	Contract Management u_{43}(0.263)	0	0.1	0.7	0.2	0
	The Early Warning Mechanism of Long-term u_{44}(0.258)	0.1	0.2	0.4	0.3	0
IPR Management U_5（0.26）	Annual Income and Expenditure Plan of IPR u_{51}(0.189)	0.2	0.2	0.4	0.2	0
	IPR Licensing Rate and Transfer Rate u_{52}(0.322)	0	0	0.4	0.4	0.2
	Investment in the Introduction of IPRu_{53}(0.280)	0	0.3	0.5	0.2	0
	Profit Contribution Rate of Industrialization of IPR u_{54}(0.209)	0	0.2	0.3	0.5	0

3 Empirical Analysis

3.1 The grade interval distribution of evaluation results

$$B = A \times R = (0.23,0.21,0.16,0.14,0.26) \begin{bmatrix} 0.006 & 0.021 & 0.106 & 0.084 & 0.014 \\ 0.044 & 0.052 & 0.101 & 0.009 & 0.005 \\ 0.016 & 0.034 & 0.67 & 0.035 & 0.008 \\ 0.004 & 0.031 & 0.071 & 0.032 & 0.003 \\ 0.010 & 0.043 & 0.106 & 0.085 & 0.017 \end{bmatrix}$$

$$= (0.079,0.181,0.450,0.244,0.046)$$

Therefore, we figure out the proportion of SF Company IPR process management at the level of "very good", "good" and "general", "poor" and "very poor" is respectively 7.9%, 18.1%, 45%, 24.4% and 4.6%, among which the sum of the middle three grades is 87.5%.

3.2 Evaluation results of the comprehensive rating

$$E_1 = V * B_1^T = (90,80,70,60,50) * (0.026,0.092,0.459,0.364,0.059) = 66.612$$

$$E_2 = V * B_2^T = (90,80,70,60,50) * (0.208,0.249,0.479,0.041,0.024) = 75.768$$

$$E_3 = V * B_3^T = (90,80,70,60,50) * (0.102,0.210,0.419,0.219,0.050) = 70.961$$

$$E_4 = V * B_4^T = (90,80,70,60,50) * (0.026,0.222,0.508,0.226,0.018) = 70.106$$

$$E_5 = V * B_5^T = (90,80,70,60,50) * (0.038,0.164,0.407,0.327,0.064) = 67.833$$

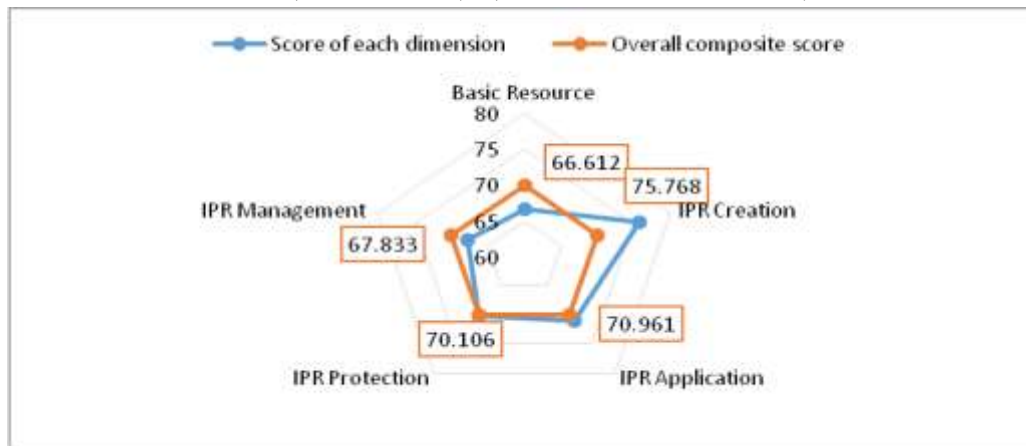
$$E = V * B^T = (90,80,70,60,50) * (0.079,0.181,0.450,0.244,0.046) = 70.037$$


Figure 1   The Radar Map of Intellectual Property Process Management Score of SF Company

The evaluation results show that the comprehensive score of the IPR process management of SF Company is 70.037, which is at the "general" level. In particular, it is subject to two factors: Basic Resources (66.612 points) and IPR Management (67.833 points); At the same time, the three dimensions of IPR Creation (75.768), IPR Application (70.961) and IPR Protection (70.106) are also in the "general" level, as shown in the Figure 1.

4 Conclusion and Suggestion

4.1 The main conclusion

Based on the Life Cycle Theory and the main content of the different stages of IPR management in SMEs, this paper constructs an evaluation index system covering five dimensions: Basic Resources, IPR Creation, IPR Application, IPR Protection, IPR Management. And taking SF as an example, it uses fuzzy composite evaluation to carry out an empirical analysis. The evaluation result shows that the current intellectual property process management of SF is in the "general" level (70.037), which is mainly controlled by two factors such as basic resources (66.612 points) and IPR management (67.833 points). At the same time, the three dimensions of IPR creation (75.768), IPR application (70.961) and IPR protection (70.106) are all in the "general" level, with a large improvement space.

4.2 Improvement Suggestions

1) Independently set up the IPR management department. Change the IPR management group formerly attached to the R&D department to the independent IPR management department, which is fully responsible for the internal and external management of intellectual property, reports directly to the general manager, and all functional departments should cooperate fully.

2) Establish the IPR management information system. According to the basic preparation-application-authorization-maintenance-operation-management of the whole process management content of IPR, establish the corresponding intellectual property query-application-analysis-maintenance-operation-evaluation six information system, to improve enterprise internal coordination and enforcement for the management of IPR.

3) Strengthen the comprehensive monitoring of key nodes of enterprise R&D projects. We can divide enterprise research and development projects into four stages: implementation, implementation and transformation, and implement comprehensive management by designing monitoring measures of key points in each stage.

4) Expand the diversification of IPR. Using the Boston matrix to analyze and optimize the conversion of intellectual property to market value, expand the intangible asset leverage effect of intellectual property through diversified management.

Impact of Eco-based Innovations on the Efficiency of Corporate Environmental Responsibility

Goli Yao Sidoine ¦ Ye Jianmu ¦ Ye Yongling [2]

Abstract: The ultimate purpose of Corporate Environmental Responsibility (CER) is to prevent harmful influence of business activities on the environment. Each company should be obligated to adhere to it since environmental pollution is a serious threat for the future of mankind. Based on this urgent need, ecological innovation appeared. It purports to make a transition from a harmful business to a more accountable one. Hence, the contribution aims at studying how different, most developing countries, have been approaching and practicing CER to propose a more practical and general framework strategy with a qualitative methodology encompassing common accepted steps to drive improvements in the efficiency of CER and Eco-Innovation. Such a framework focuses on innovation as a key to business success aligned with CER and it is based on previous eco-based innovations in such a context. Necessary data will be collected by a survey questionnaire about several case studies.
Key words: Corporate environmental responsibility; Innovations; Environment

1 Introduction

Innovation is regarded as a core driver of the development and success of any business. It has multiple definitions, and several of the most succinct and relevant ones posit it as the implementation of a novice or significantly enhanced product, service, process, or method, whereas others underline that innovation can have continuous connotation, and mean a course of improvement (Reinlie, 2017). In Rexhepi, Kurtishi and Bexheti (Kurtishi and Bexheti, 2013) they stated, "innovation in implicit way tends to be one of the main drivers of competitiveness" (p. 540).

Innovative technologies must be safe, justified and constructive in order to become a valuable strategic tool for the company. Along with this, the value for society and accountability for the corporate performance has become a key issue in the modern business world. Diverse novice types of innovation have emerged nowadays, reflecting the aforementioned stance of harm to the environment. Eco-innovation and social innovation are among them. According to the report by the Organization for Economic Co-operation and Development (OECD), eco-innovation is defined as "innovation that reflects the concept's explicit emphasis on a reduction of environmental impact, no matter whether or not that effect is intended" (OECD,2009b). Furthermore, eco-innovation, or green innovation in other words, is targeted at decrease of resources and energy consumption "while promoting sustainable economic activity" (OECD,2012). Nevertheless, many companies focus on receiving a higher profit and neglect the harm their performance imposes on the environment. The concept of corporate environmental responsibility (hereinafter, CER) implies the accountability of each company for the society concerning its actions. To be more precise, organizations claim the duty to abstain from such types of business activity that can damage the natural environment either in direct or indirect way. As a result, the notion of eco-innovation appears implying performance that contributes to a sustainable development that creates new products and services targeted to both provide significant business value and at the same time decrease environmental damage. So, what is the actual impact of eco-based innovation on the enhancement of efficiency of CER? The present paper proposes to study relevant, credible and up-to-date literature focused on eco-based innovations outlook in the context of CER and its current approaches and practices in developing countries and provide a general methodology based on major issues identified during the secondary research and the model of efficiency criteria from the framework. A qualitative research is chosen in order to collect essential data on the issue in question. The study relies on the literature review, a number of case studies and a survey questionnaire.

2 Examples

There are several cases that illustrate how ecological innovation can presently be employed as a constructive tool of CER. For example, research on the issue of CER actualization and its potential efficiency in one of the low income countries, Bangladesh, was conducted by Belal, Cooper, and Khan

in 2015. This country is in the process of transition to middle income countries, but huge amount of costs spent on dealing with urgent environmental issues is a serious obstacle for this process (Belal, Cooper, Khan, 2015). Therefore, the initiative of CER actualization is regarded as a potential solution in the situation of Bangladesh (Belal, Cooper, Khan, 2015). It is recommended to involve NGOs to this process as an approach to the introduction of 'surrogate accountability' performed via third parties in order to contribute to the vulnerable stakeholders. As the scholars underline, such an alternative approach to the issue of corporate responsibility is expected to have more significant "potential in developing countries where NGOs might act as surrogates for victims of corporate activities and sanction the power wielders on behalf of the vulnerable with a view to redress the balance of power and hold the corporations to account" (Belal, Cooper, Khan, 2015).

Another example that is relevant to the given discussion concerns process of eco-innovation in industrial water-service systems (Levidow et al., 2016). Levidow, Lindgaard-Jorgensen, Nilsson, Skenhall, and Assimacopoulos conclude that there are many challenges in the implementation of eco-innovations in the given sphere, but the overall potential of their use is significant, and further studies of the issue in question are recommended (Levidow et al., 2016). Finally, Asfaw, Botes and Mengesha present a case of Ethiopia as a relevant sample of developing countries implementing CER (Asfaw, Botes and Mengesha, 2017). The experts also conclude that influence of NGOs in the given context will be an optimal solution (Asfaw, Botes and Mengesha, 2017). Their clearly set and constructively developed strategies are expected to contribute to formation and effective functioning of green economy in the country (Asfaw, Botes and Mengesha, 2017). The policies should be actualized via cooperation with government, media, educational institutions, and primary stakeholders (Asfaw, Botes and Mengesha, 2017).

There are five major gaps in the presented research, namely, 1) strategies of NGOs in developing countries aimed to prevent improper use of power and impact. NGOs should cooperate with governmental organizations and at the same time focus on the ultimate purpose of CER. The urgency of the given gap is confirmed by Asfaw, Botes and Mengesha (Asfaw, Botes and Mengesha, 2017); 2) there is a gap in the vision of strategy that can be adhered to and developed by NGOs in addressing the issue of CER. Actually, each developing country has similar issues in general, but peculiarities of their implementation as well as proximity to higher level of development differ. Hence, more alternatives and examples of CER implementation with all the challenges and potential outcomes should be investigated more as supported by Asfaw, Botes and Mengesha (Asfaw, Botes and Mengesha, 2017); 3) there is also a gap in addressing CER issues under circumstances of industrial efficiency. As a rule, the changes implied by CER require time, costs and efforts. Hence, it is crucial to explore more on the most optimal solutions for such transitions. It is especially relevant in developing countries where the potential is rather limited and the current environmental problems are serious. This issue was approached by Levidow, Lindgaard-Jorgensen, Nilsson, Skenhall, and Assimacopoulos superficially (Levidow et al., 2016); 4) the study of Bangladesh conducted by Belal, Cooper, and Khan reveals that there is a gap in effective and affordable strategies on financial issue for the developing countries. To be more precise, the options for acquisition of the costs for changes that are usually a deficit in developing countries should be studied as underlined by Belal, Cooper and Khan (Belal, Cooper Khan, 2015); 5) finally, the major premises of effective development of green economy in developing countries is considered to be another gap in the area of concern. Belal, Cooper, and Khan dwell on the issue of 'surrogate accountability' (Belal, Cooper, Khan, 2015).

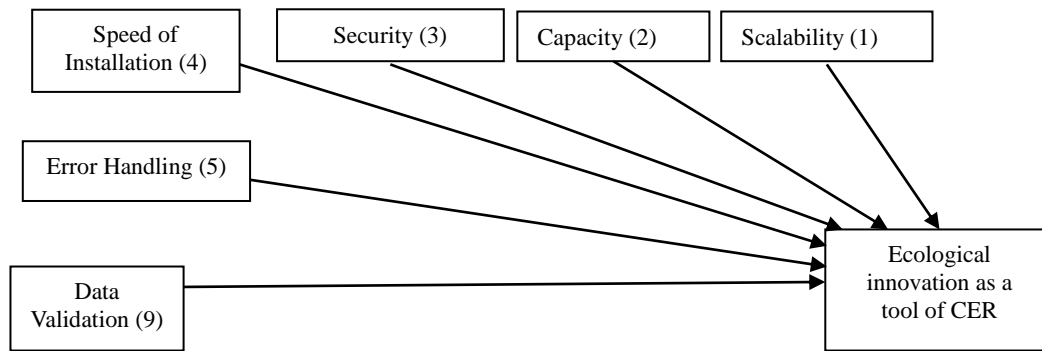
Figure 1 presents a framework that illustrates the major aspects for ensuring efficiency of eco-based innovation in terms of CER provision. These aspects include *scalability, capacity, security, speed of installation, error handling and validation of the data*. These constituent elements of the efficiency paradigm are expected to gauge the actual positive influence of ecological innovation of CER-related organizations in developing countries. Scalability is needed to provide maximal utility of the discussed strategies. Capacity of each country is a crucial factor as far as it predetermines perspectives of use of ecological innovations and transition to CER in business sector. Security is a crucial element that prevents business from failure in financial terms and environment from actual damage. Speed of installation is also a serious issue in the given context since many businesses refuse to shift to CER since it requires not only money, but also time. Error handling is a crucial issue of the future. The stakeholders should be ready to face the errors and deal with them constructively. The potential solutions should be developed beforehand so as to respond timely. Finally, validation of the data is a step to the next level of eco-based innovation and effective CER since it presents background for further improvements and better outcomes.


Figure 1　Framework Ensuring Efficiency of Eco-innovation in Terms of CER Provision

3 Data and Methodology

The given methodology will include, as secondary research, a literature review of credible, reliable and up-to-date sources that feature the core concepts of the research and relevant case studies in the area of interest. Primary research encompasses conducting survey and consequent analysis of the acquired responses. The results lead to the ability to identify several ideas of innovation eligible for further practical use or future, more specific exploration.

3.1 Method One

The present study adheres to the qualitative approach. The reason is that this approach aligns with the major aims of the given research, namely, to provide in-depth insight into the issue in question, analyze it from different angles and acquire as much details on the topic as possible. According to Hancock, Ockleford and Windridge, qualitative research "focuses on reports of experience or on data which cannot be adequately expressed numerically" as well as "focuses on description and interpretation and might lead to development of new concepts or theory, or to an evaluation of an organizational process" (Hancock, Ockleford, Windridge, 2009). Along with such, this type of research uses flexible, emergent and at the same time systematic research process (Hancock, Ockleford, Windridge, 2009). Hence, the given methodology for the research requirements fits impeccably.

The research question of the present study is: What is the actual impact of eco-based innovation on the enhancement of CER efficiency?

3.1.1 Discussing about Method One

The focus of the study will be narrowed by means of several case studies representing the essential data needed for conclusions and further application of research results. The study will also identify directions for further research and potential implications for practice with CER in developing countries.

3.2 Method Two

The overall quantity of the respondents necessary for the study was 100. A back-up group of 20 more people was formed in case some of the respondents declined to partake, failed to complete the survey or provided incomplete responses. Each individual received a welcome e-mail letter with basic terms, guarantees and form of informed consent. Along with this, each person was assigned to a group. The date the survey was to be distributed and time for its completion (1 week) were also mentioned in the letter. As soon as 100 of the respondents from the main group provided their consent and confirmed participation, the survey questions were approved, and the surveys were returned by the due date. Only two respondents failed to provide their feedback, so it took 10 additional days to contact the representative of the back-up group and receive their responses.

3.2.1 Discussing about Method two

Once 100 responses were collected, each aspect was analyzed and arranged into a set of inferences. Consequently, the outcomes of the primary and secondary research were compared and aligned or contrasted accordingly. Finally, a concise and comprehensive report was developed, revealing core findings, discrepancies and challenges of the issue in question. The most valuable empirical contribution of the study was a set of innovative ideas designed based on the given research course.

4 Results

The results acquired via online survey were structured in accordance with the core efficiency

criteria presented in the model. All the participants of the study confirmed that proper implementation of eco-innovative technologies impacted efficiency of CER positively. 78% of the respondents agreed that eco-innovation always requires making crucial changes, but at the same time leads to better performance outcomes and higher quality of the final product or service level. Some respondents noted in their additional comments to the survey, that CER was impossible without eco-innovation and that awareness of urgent necessity to implement CER in all countries by all companies is a key to the future with resources available and natural conditions favorable for all living things on Earth. Seven respondents claimed that CER is being implemented too slowly and such a pace does not suffice for timely changes needed to save the natural capital.   One of the participants posited that the course of implementation of eco-innovative technologies endangered the survival of many companies as far as it required much time, efforts, alterations and expenses, and, as a result, the company could face potential bankrupt since revenues could decrease or investors could pull out. This is an important aspect that should be studied further in the future studies.

4.1 Scalability

The results on the criteria of scalability were as follows: 76% of the respondents stated that eco-innovation contributed to scalability, but only in the long run. Some respondents highlighted that their business needed around two to three years to cross the line of proper scalability after the introduction of eco-innovation technologies (34%), whereas others stated that qualitative implementation of eco-innovation led to positive results in terms of scalability of the business within a year (28%). The rest of the respondents stated they had no experience with eco-innovation aligned with scalability issues.

4.2 Capacity

Capacity criterion acquired the following research outcomes: the prevailing majority of respondents (58%) stated that the primary threat to capacity of the business was eco-innovations; some respondents claimed it was of utmost importance to start eco-innovative practices only when the program aimed at CER provided transparent vision of adjusted performance that did not affect capacity, whereas others claimed it was crucial to start eco-innovative practices as soon as possible since it was hard to construct an impeccable scheme for every type of business without affecting any of the currently studied criteria of efficiency. One of the respondents expressed in the section for additional comments that capacity should be a main concern in the long run, i.e., the capacity decreased in the course of CER actualization is a logical consequence of serious transformations, and should be endured for the sake of the ultimate purpose – better capacity in the future.

4.3 Security

Security issue received most of the attention of respondents in the section of additional comments. The following aspects were addressed: according to 98% of the respondents, security was considered to be the major concern in eco-innovative practices; 44% of the participants believed that security was a key measure in constructive eco-innovation; 28% of the respondents claimed they improved security in their businesses via introduction of eco-innovation, and 3% of them stated innovative technologies were hazardous to their businesses on the initial stage of implementation. 14% of the participants also highlighted that initial plan of implementation of eco-innovative technologies should include the predictions for potential threats to security and solutions or preventive measures. Furthermore, 7% of the respondents believed that eco-innovation could become a hazard to overall security measures only in cases in which it was implemented or conducted improperly. Finally, 78% of the participants also mentioned that security was a consequence of constructive and qualitative eco-innovation and adequately functioning business.

4.4 Speed of installation

Speed of installation was the next aspect studied in the given research. 77% of the respondents stated that implementation of eco-innovation was proceeding too slowly. Some respondents commented that they had the following problems because of the low speed of installation: loss of investors because of incremental rates of decreased revenues (11%); loss of partners because of failed deadlines and terms of their partnership (18%); reduced sales (12%); and lower rates in performance in the annual report (6%). On the other hand, three respondents mentioned that the slow speed of installation could be improved through higher expenses. One of the participants also added that speed of installation in his experience directly depended on the competence of the team. Finally, 28 respondents mentioned the need for constructive, maximally detailed plan of installation as a core basis of timely implementation.

4.5 Error handling

Error handling was the most controversially perceived aspect in the context of the given research.

To be more precise, 52% of the respondents believed that it would be impossible to predict and prevent all the crucial errors in the process of implementation of eco-innovative technologies. Furthermore, the main factors contributing to effective error handling were identified as: timely detection of error, highly competent personnel, plan for prompt solution of the errors and their consequent prevention, strong security system, and maximal alignment of business capacity with requirements of eco-innovative technologies. Finally, proper error handling was considered as a significant stage of development of the company in the process of eco-innovation implementation.

4.6 Data validation

Data validation is a final criterion of efficiency used for evaluating positive contribution of eco-innovation to CER in the modern business world. According to the survey completed by those 100 participants, 79% claimed that data validation was not a problem provided all the previous stages of eco-innovation implementation were conducted properly and timely. Still, the respondents were asked to list the main challenges and drawbacks they faced in the context of data validation, and the most common responses were the following: omission or confusion of data that led to data corruption and security vulnerability; insufficient amount of data necessary for valid outcomes; and improper choice of validation method. A plurality (46%) highlighted omission or confusion of data as a major reason of unjustified validation results. 23% of the respondents claimed that such unjustified and corrupted results led to serious problems in overall business performance consequently.

5 Conclusion

Thus ecological innovation can contribute to the efficiency of CER in developing countries assumed the financial support, time and effort are provided. Furthermore, clear strategies are also needed to provide maximal efficiency. Based on the research, it is recommended to actualize eco-based innovation in business domain of developing countries with active engagement of NGOs as third parties. Moreover, a framework that encompasses main efficiency criteria was constructed. The framework includes scalability, capacity, security, speed of installation, error handling and validation of the data.

The Effect of Innovation Through Research and Development on Economic Inclusive Growth in 35 OECD Countries

Maman Ali M. Moustapha, Yu Qian
School of Economics, Wuhan University of Technology, Wuhan, P.R China, 430070
(E-mail: moustafali8@yahoo.fr, yuqian@whut.edu.cn)

Abstract: The main objective of this article is to analyze the effect of research and development (R&D) expenditures on economic inclusive growth in the Organization of Economic CO-cooperation and Development (OECD) countries from 2000-2016. For this reason, we constructed a multiple regression model which indicated an increase in research and development expenditure as percentage of GDP by 1% would cause an increase of real GDP growth rate to 2.83 %. This result can be useful for the policy makers, government and institutions regarding the innovation area and economic inclusive growth perspective.
Key words: Research and development; Economic growth; Innovation; OECD Countries

1 Introduction

The effect of research and development (R&D) activities on economic performance has been intensively examined both by researchers and policy makers. In the theoretical literature, economic growth models emphasize the importance of technical change and assert that technological development is the main driver of economic growth in the long run. At present, developed countries largely base their economic growth on the creation and use of knowledge that objectified in technological changes. It has become a fundamental creator of competitive advantage of companies and countries on the world market (Lucas, 1988, 1993). The study of knowledge as a key determinant of economic growth is especially present in so-called new growth theory. The two most important directions of new growth theory are endogenous growth models and evolutionary approach to presenting the complex of technological change as a source of economic growth. The common thread is their attempt to arrive at a proper answer to the question of what are the key drivers of complex technological changes.

Endogenous growth models follow Schumpeter's idea of the importance of organized knowledge creation in generating economic growth based on research and development (Schumpeter, 1942). Romer (Romer, 1986, 1987) marked a new theoretical approach to the analysis of economic growth factors, the so-called endogenous growth by formalized the idea that knowledge leads to continuous economic growth. In Romer's model, growth rests on the results of research and development, substantiated in technological changes, which companies use to maximize profit. This feature of technological progress has been particularly studied by Grossman and Helpman (Grossman & Helpman, 1991) and Aghion and Howitt (Aghion & Howitt, 1992, 1998).

The view that the complex of technological changes represents the most important source of economic growth first entered economic science when precisely promoted by the representatives of neoclassical economic thought. The neoclassical growth theory predominantly rests on Robert Solow's model, developed in the mid-1950s. (Solow, 1957) came to the conclusion that approximately 50% of historical growth in industrialized countries cannot be attributed to the growing use of physical capital and labor, but to the third factor, the so-called residual. Residual includes all growth factors of an intangible nature, such as the development of existing, and the creation of principally new, means of production, changes in education and expertise of employees, research and development, changes in organization and methods of production.

The question of relationship between the activities that drive the complex of technological changes and economic growth of individual countries in previous years can be empirically confirmed. In this regard, the activities of the country are represented by a large number of indicators that trigger technological changes. One of the indisputable indicators of such efforts is the GERD (Gross domestic expenditure on R&D) indicator. The GERD as a percentage of GDP presents research and experimental development (R&D), comprising creative work undertaken on a systematic basis in order to increase the stock of knowledge, including knowledge of man, culture and society and the use of this stock of knowledge to devise new applications. The research in this paper covered 35 OECD countries, observed in the time frame 2000–2016. Using the multiple regression method, except for the GERD indicator, the following have been used as control variables, relevant to the generation of economic growth: gross capital formation, government final

consumption expenditure and fertility rate. The paper will present the results obtained by the multiple regression method, based on a sample of 35 OECD countries in the period from 2000 to 2016.

2 Data and Methodology

The expression of the levels of innovation activities in national economy is an important factor in empirical research on the effect of innovation on economic growth rate. The share of research and development expenditure in GDP is the most used data on innovative activities in one country. This approach is highly acceptable because it is suitable for quantitative and qualitative analysis.

In our study, the dependent variable is the real growth rate of gross domestic product. Data on this value has been taken from the official statistics of OECD and World Bank data base. It is known that gross domestic product is a measure of economic activity in a national economy, measured by the value of output (goods and services). The main task of this study is to determine whether the research and development expenditure has an impact on economic inclusive growth in OECD countries.

Table 1 Descriptive Statistics and Names of Variables

Variable	Obs.	Mean	Std.dev.	Min	Max
Real GDP Growth Rate	275	1.891471	1.652292	-3.471759	4.089127
General Government Final Consumption Expenditure as a Percentage of GDP	275	31.25807	5.092584	23.2	39.29872
Gross Fixed Capital Formation as a Percentage of GDP R&D Expenditures as a Percentage of GDP	275	9.771874	4.760953	2.27187	17.27188
Fertility Rate	275	24.46158	5.077135	16.4	32.49569
	275	1.688235	.0600245	1.6	1.8

In our research, we use a multiple regression model with fixed effect (FE). The reason for such an approach lies in our decision to analyze the influence of selected variables that change over time. The fixed effect explores the link between, on the one hand a dependent and on the other hand independent and control variables, within each entity individually in our case, the observed countries. Each entity has its own characteristics, which determine the influence of independent and control variables on the dependent variable. Another important assumption of the FE model is that those time-invariant characteristics are unique to the entity, and should not be correlated with other entities' characteristics. Each entity is different, therefore, the entity's error term and the constant (which captures individual characteristics) should not be correlated with the others entity's error terms (Wooldridge, 2002).

3 Regression Tests and Results

We suppose that every country has some characteristics that influence real GDP growth differently. The mean is based on observations from all countries, and that could be the reason for a great standard deviation. When we use fixed effect model to get entity error, the error is correlated with other predictors in equity. Those entity errors are unobserved time invariant characteristics of every country.

First, we run a simple linear regression. The dependent variable we use is real GDP growth rate. The independent variables are government final consumption expenditure, gross fixed capital formation, R&D as a percentage of GDP, fertility rate. The regression is given in Table 2.

Table 2 Simple Linear Regression

Source	SS	df	MS	Number of obs	275
				$F_{(3,271)}$	65.82
Model	14.8945093	3	3.72362732	Prob >F	=00000
Residual	28.7756916	271	2.61597196	R-Squared	=0.3411
Total	43.6702009	274	2.91134673	Adj R-squared	0.1015
				Root MSE	=1.6174

Real GDP Growth Rate	Coef.	Std.Err	t	P>t	95% conf.interval	
General Government Final Consumption Expenditure as a Percentage of GDP	7.499429	11.50301	0.65	0.528	-17.8185	32.8173
Gross Fixed Capital Formation in %GDP	-29.90876	17.66582	-1.69	0.119	-68.7909	8.97345
R&D Expenditure Percentage of GDP	22.49319	24.53908	0.92	0.379	-31.5169	76.50334
Fertility Rate	9.621684	9.403062	1.02	0.283	-11.0743	30.3176
-cons	505.9286	447.9173	1.13	0.283	-479.93	1491.78

The value of R-squared, which is 34.11% of the variance of the dependent variable real GDP growth

rate, is explained by our regression model. We are basically interested to find it out if there is any evidence between our independent variable and a dependent variable controlling for the other variables. The conclusion arising from Table 3 is that, with the clause ceteris paribus, an increase in the share of research and development expenditure in GDP by 1% will have an impact on the real growth rate of GDP by 1.21 percentage points in the observed economies in the observed period. In order to improve the validity and applicability of the model, i.e. that the variable government final consumption expenditure as a percentage of GDP has a lower p value, but also point to the growing importance of investment in research and development for economic growth, we performed the time adjustment of our control variables. Therefore, on the basis of a number of iterative steps, we constructed a multipleregression model, in which we observed the effects of fertility rates with a one-year lag (Table 4).

U_i=0						

Table 4 points to the conclusion that, with the clause ceteris paribus, an increase in the share of research and development expenditure in GDP by 1% will have an impact on the growth rate of real

GDP by 2.83 percentage points. The coefficient of determination in this case is higher. We can construct one model by adding to this the fact that the F-test is a good value, we confirm that all coefficients are different from zero.

4 Conclusion

After reviewing the relevant literature and empirical studies that link the complex of research and development with economic growth, in this paper we set the research question of whether the research and development expenditure in the period from 2000 to 2016 in the OECD countries had a positive effect on economic inclusive growth. For this purpose, we constructed a multiple regression model, in which the dependent variable was the real rate of economic growth, and the independent variable the value of research and development expenditure as a percentage of GDP. The obtained results unambiguously confirmed that research and development have a positive effect on the real economic growth rate. The constructed multiple regression model with fixed effects showed that, with the application of the clause ceteris paribus, an increase in the share of research and development expenditure in GDP by 1% causes GDP growth of 2.83 % in 35 countries of the OECD in the period 2000 to 2016.

Abstract: Semiconductor companies are constantly bounded by customer demands for smaller, lighter, faster and more powerful devices. They are continuously introducing new models and adding more features to enhance their devices. However, the product life-cycle curve in semiconductor devices today is shorter and steeper than ever before. With shortened life cycle, the high management executives are difficult to make a right decision which regions and technologies they need to focus more. In this article, we propose a new management strategy for semiconductor companies to compete in this smart era by using patent analysis with link mining method. We focusd on an advanced FPGA technology because this market is mainly driven by raising demand for optimization in Big Data analytics, growth of Internet of Things (IoT), huge adoption in smart-phone and held devices and growing adoption of Advanced Driver Assistance System (ADAS). We extracted the information from Classification Patent Codes (CPC) that submitted by Intel, Altera and Xilinx suppliers using link mining as the analytical method. We analyze the metadata and create a graph theory to see the degree of the nodes. The experimental results showed the technological structure and recommendation for the semiconductor management which regions they need to pay most attention. In conclusion, this patent analysis with the link mining method can help the top management predict where the business model of semiconductor industry will be shifted.
Key words: FPGA; Patent; Technology structure analysis; Link mining; Graph theory

1 Introduction

The semiconductor industry has evolved into one of the critical foundations for the global economy and this industry goes to keep up with developments in a world that is rapidly moving beyond smart. In the biggest semiconductor exhibition/conference, SEMICONWEST, the key phrase was "SMART STARTS HERE" last year, but this year is changing to "BEYOND SMART". "Beyond smart era" means all things are digital, integrated and all connected without human intervention. It also means everything are smart and intelligent like smart home, smart phone, smart machine and others by using IoT (Internet of Things), Big Data or AI. Furthermore, it means experiencing the cutting-edge of changes driving the industry forward. One example of smart-era technology is IoT, which is a network of physical devices, home appliances and other items embedded with electronics, software, sensors, actuators and network connectivity which enable these objects to connect and exchange the data. Hence, the demand for collecting a large amount of data and processing the data in real time also increase. However, the industry is not without challenges and these challenges must be addressed if we want to continue on historic growth track. One of the problems, due to short product life cycle, the top management often confused in which market and field are the most worth for them to penetrate. In addition, in term of technologies the processing performance needs to be improved on both the edge- and the cloud-sides.

A semiconductor company must decide what areas it plays in and equally, what areas it does not play in. It requires a lot of more detailed works and faith to choose the right target market and segment, and devise a compelling, hard-to-imitate value proposition, backed up by internal resources and patience. It must focus equally on strategy and execution – in all areas of its business. It requires an increase in risk appetite, a change in mindset, an ability to make sense of the environment, and agility – and that is a long change journey to undertake. The top management needs to have three fundamental aspects of marketing which are analyzing market, targeting markets and finally finding the best way to sell semiconductor products to those market. Targeting and positioning are called sources of sustainable competitive advantage. To do market analysis, there are two major aspects which are identifying and segmenting the market. The process of analyzing and targeting market can be applied by patent analysis with link mining method.

In addition, edge computing becomes an essential component of the data driven applications. Usually users install and run edge computing software in existing environments. The hardware can be

dedicated or shared with other services. In many scenarios, it is common to use the system LSI called embedded System-on-a-Chip (SoC). It satisfies reducing power consumption and improve reliability. All the sensors talk to the local edge devices which manage the connectivity with the cloud. Amazon Web Service (AWS) and Microsoft Azure are examples of device edge software. A large amount of data will be transmitted from edge devices to the cloud to server installed on the cloud side. The real time processing to transmit data is very crucial. Hence, this will definitely increase the processing power. Therefore, in addition to high-performance CPUs, high performance GPUs and large capacity memories are required to perform parallel calculation.The SoC is the core of the edge devices, but it is difficult to apply to edge devices of small production because of high price and long lead time. In addition, servers on the cloud side mainly use Intel x86, AMD and NVIDIA GPUs have a lack of flexibility to support new protocols. To solve these problems, Field Programmable Gate Array (FPGA) has been proposed. FPGA market is growing in the rapid pace. Owing to its high adoption in smart phones and handheld devices, its implementation in wireless networks for increasing the bandwidth and growing demand for electronics components in automobile industry is driving the market growth. FPGA also can be used as the SoC and no limit on how many operations can be simultaneously executed by a computer. The development period of FPGA is also much shorter because the manufacturing process is unnecessary, and it relatively has lower power consumption. This FPGA technology is very suitable for implementing CPU accelerators and user protocols.

Intel (former Altera), Xilinx, Microsemi and Quicklogic are key players and supplier of FPGA. In recent years, Xilinx adds an ARM core to its FPGA to create FPGA SoC. Intel also has released a chipset for server combining its own CPU and FPGA and reference design for fog computing.

This paper focuses on capturing and finding the technological field where FPGA suppliers focus on. We extract the information from Classification Patent Codes (CPC) submitted by these suppliers and usage of link mining method as the analysis method. It is a method of abstracting the elements and their relationships in the analysis subject into the nodes and the edges to create a graph, and search its structural features. There are several kinds of graphs such as weighted / unweighted and directed / undirected-graphs. And there are various kinds of indices which represent the structural features such as order, centrality, cluster coefficient, transitivity, density, and so forth. We analyze the metadata and create the graph theory to see the degree of the nodes. This paper also analyzes the market and identifies which markets these suppliers should focus on.

2 Related Works

This chapter describes related work on our proposed method. Many market analysis about semiconductor industry has been made so far. Introduction of Semiconductor Marketing book proposed FPGA has several attributes that provide companies competing in this space with defensible long-term positions in the market. The two main players in the FPGA area are Xilinx and Altera. The FPGA industry also benefited the foundries by helping the Taiwanese foundries take market share away from ASIC companies, primarily located outside of Taiwan."Sustaining Moore's Law Uncertainty Leading to a Certainty of IoT Revolution" by Ravi Batra is precise in his analysis that it is very important for the semiconductor industry professionals to look for new ideas to sustain a progress of Moore's Law.

Mark Bohr, a senior fellow in Intel manufacturing group, said that what started out as an observation become a guide for them that they needed to follow and if possible, they want faster than anyone else in the industry. He also doesn't think Moore's Law will end, it will evolve and change in terms of what they do. The semiconductor industry's ability to innovate and develop ICs of one sort or another will continue for a long time.Masashi Shibata et al. proposed the trend analysis of the technology development on FPGA with Machine Learning based on the public information. Thus, succeeded in revealing the companies' technological transition and their differences and cmmon points from the results of extracting the graphs' features.

In term of technology, many technical analysis methods using the patent have been made so far. They are performed for the purpose of business solution.TRIZ (TeoriyaResheniyaIzobretatelskikhZadatch) aims at performing technical development based on the structure of problem solving which appears repeatedly in the patent. Kawakami et al. propose the inconvenience idea gains support system aid of inventive problem solving theory TRIZ.Thus, many measures have been taken as having centered on the patent for a business solution.

Then, we look down about the patent analytical skills. One of the techniques of patent information analysis is the patent mapping. Kiriyama made content analyses with this method. Shide et al. performed

finding the change of the positioning for customer of research and development activities of the company using the patents analyses. Kimura proposed a technology evaluation method based on patent analysis for technology strategy planning. As for the analysis of important information derived from patent analysis, Carpenter analyzed for important cited patents. Muguruma showed the validity of the patent citation analysis to propose FCA (Forward Citation Applicant) map. Sato et al., proposed the importance calculation method of the patent document based on the citation information. Ogawa et al, proposed a basic patent extraction based on the citation information. For citations, Albert conducted a validation of citation for important patent among the industry.

In place of which were performed heuristically so far, as for the patent classification, such as category of invention and problem, Tanaka proposed method of extracting the feature automatically. Yamashita proposed a method of surveillance technology and specific method of patent classification with text mining. Yamamoto et al, proposed a method to enhance the compatibility of the search by applying the information of related patent documents in search of academic papers. Yamamoto proposed a method to find the scientific papers with a variety of further information. Kleinberg extracted the topic and description of the relationship with graph theory. Eto proposed a measure of co-citation based on structural units of the paper. Ueda proposed the technical analysis with an active mining method that focuses on the cognitive processes of the patent examiner, utilizing patent classification such as IPC (International Patent Classification), FI (File Index), and F-term (File Forming Term). Thus, with the application of the technology of intelligent informatics, knowledge extraction is performed to the patent information.

Then, it looks down about the mining technology, which is one technique of knowledge extraction. The relationship of analytical methods and technologies, technology analysis method using patent information is described.Structured technique using graph theory has been applied in various fields. For instance, chemical formula, WWW (World Wide Web), social network, statements with grammatical structure and dependency. A graph is made for expressing the structure of the object, and make it use for the analysis, finding the partial graph which occurs frequently from the set of graphs.From the results of the related work studies, the relationship is able to describe using this method. This paper is employed link mining for the patent analysis.

3 Experimental Configuration

This chapter describes the configuration of this experiment.In general, patent information consists of metadata, such as application date, applicant, classification codes, literal information and graphic information. Classification codes include those used internationally, such as IPC, CPC and those used domestically such as ECLA, USPC, FI, F-term and so on. IPC and CPC indicate the technological fields of the main topics of the patent's claims.

CPC is the classifier that began granting from 2013. It is retroactively assigned to patents which filed before 2013. It has a hierarchical structure like other classifiers. It is separated Section (Alphabet 1 character) - Class (2 digits) – Subclass (Alphabet 1 character) - Main group – Subgroup hierarchically. There are about 250 thousand groups in total. In this experiment, four alphanumeric characters up to subclass are used. Up to subclass, there are 649 categories.

Two kinds of CPCs are given to a patent. One is Head-CPC and the other is Sub-CPC. Head-CPC indicates the technology field which the patent mainly belongs. Sub-CPC indicates the technology field which is related to the patent. The number of CPC varies depending on the relevant technical field of the patent. For example, Intel's patent: 9,532,239 has 5 CPCs such as G01S 5/14; H04L 43/08; G01S 13/876; G01S 13/765; and H04W 24/02, and its Head-CPC is G01S 5/14. Here we focus on the US patent owned by FPGA suppliers: Xilinx, and Altera acquired by Intel in 2015. The analytical period is for 16 years from 2001 to 2016. The full text database of the U.S Patent and Trademark Office is used as experimental datasets. Applicant: Altera, Xilinx, and Intel are used as search keywords. As a result, 3,884, 3701, 34,316 patents are obtained respectively. Among them, filed in 2001 through 2016, 3,302, 3,113, 26,949 patents are analysed.

At first, the patents are grouped by every 6 month. Then, for representing the technological structure of a patent, a directed graph is created for each patent. CPCs given to the patent are used as nodes, and edges are drawn between Head CPC and Sub CPCs. The edge's direction is Head CPC to Sub CPCs. There is no edge between Sub CPCs. The graph is unweighted graph. Fig.1. shows an example of the graph of each patent.Then, semi-annual graphs for each supplier are created by overlaying patents' graphs in every 6 month of application. The number of link appearance is accumulated for every appearance of

the edge. Thus, the graphs are directed and weighted graphs.

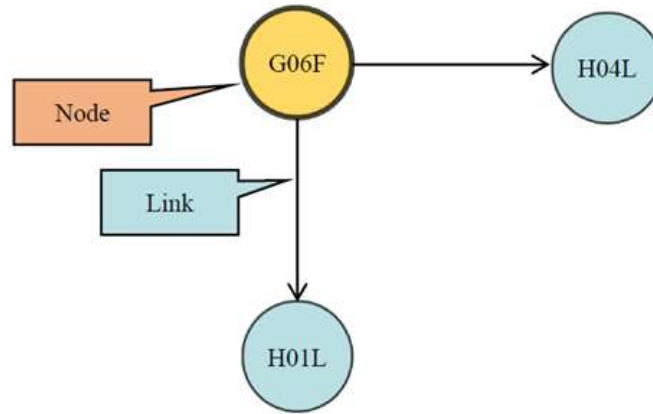
In this experiment, we focus on the degree of each node of the graph. Degree represents the number of edges connected to a node. The nodes connected with more edges are considered to be core technologies at that time. In Fig.2, the size of a node indicates the number of the degree of the node. The thickness of an edge indicates the number of times, and the nodes have the relation as the Head CPC and the sub CPC. Therefore, 4 CPCs out of 11 have high degree. The graph is a directed graph. Therefore, the degree is calculated by adding inward degree and outward degree.


Figure 1   Directed Graph of Each Patent
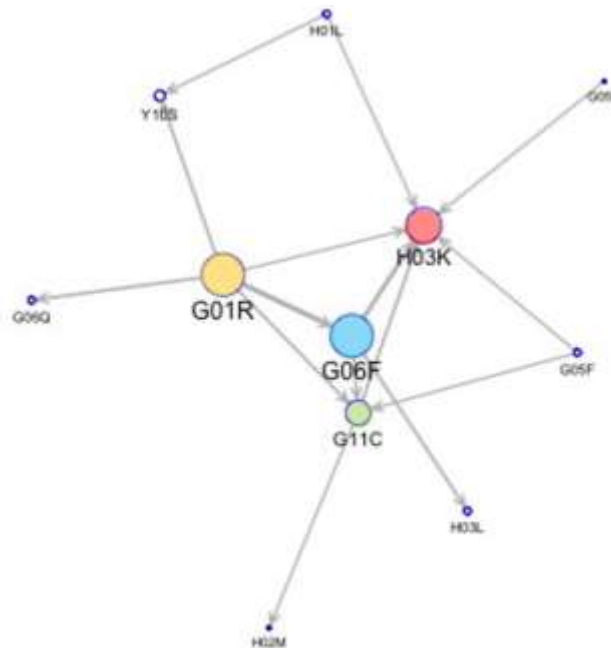

Figure 2   Semi-Annual Graph

4 Experimental Results

This chapter describes the results of the technological structure analysis. Table 1 shows the five CPCs which have the highest degree for each supplier for every 6 month. We analyze giant FPGA companies Altera, Xilinx and Intel, even though Altera is now part of Intel, we still compare their data to see where the business shift after Intel purchased Altera. All of the three companies have high degrees of G06F, H01L, and H04L throughout the period as shown in Fig. 3. This means the field of data processing, semi-conductor device, and digital data transmission continue to be important for these companies throughout the period.

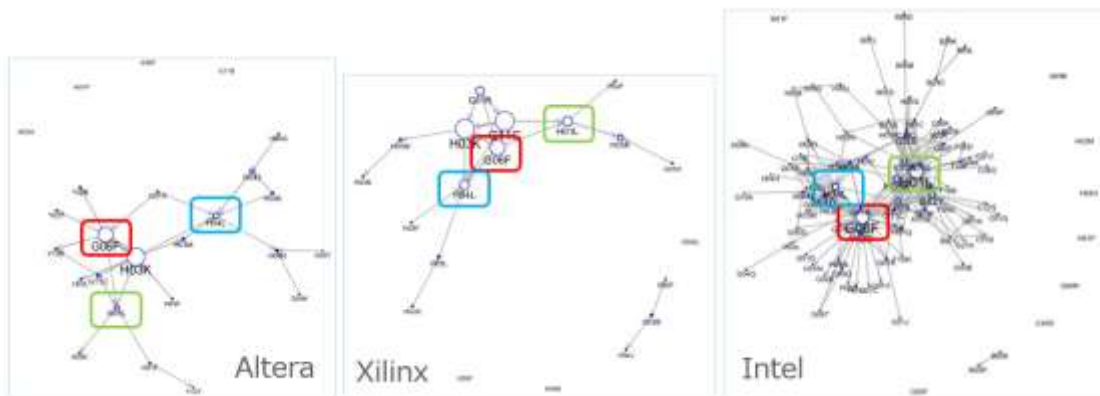

Figure 3　Technology Strucuture

Intel purchased FPGA-maker, Altera, in 2015. When we observe from high degree CPC list in Table 1, before Intel purchased Altera, the degree of H05K is high in the first half of the period which is focusing on technology development for chipset boards. During the latter half, the degree of H04B and H04W becomes high. It shows that the direction of development shifts to wireless transmission and data transmission. Comparing with Altera, the degree of H03K and G11C is high throughout the period. It shows that the fields of electric circuitry and memory are important and core business of this company. It means, that when Intel shifts their business to wireless transmission and data transmission, Intel plans to purchase Altera that are good in electric circuitry and memory. All of wireless transmission and these technologies are using FPGA that can be reprogrammed after it was made. Intel predicts FPGAs opportunity everywhere and purchased Altera because of Intel and Microsoft Azure project that required FPGA from Altera.

In term with Xilinx, the CPCs appeared are mostly common like Altera. Xilinx business focuses on electric circuitry and memory. At different points, Altera has a high degree of H03L (automation control circuit) throughout the period and Xilinx has a long period of high degree of G01R (measuring electric

variables). In addition, the degree of H04B (wireless transmission) has been increased at the end of the period.

Therefore, we collect Altera, Xilinx and Intel-CPCs to analyze the reason behind and to see where these giant FPGA suppliers shift their business model. In addition, this patent analysis with link mining method can help the top management semiconductor companies compete in competitive advantages and targets in which segment of market they need to focus based on these suppliers trend.

5 Conclusion

This paper proposes an efficient method for semiconductor management for analysing the semiconductor business model trend with machine learning. We gathered the US patent data filed by FPGA suppliers. We employed the patent classifier to make the technology structure graph. With the proposed methnod, we succeeded in extracting corporate focusing business and technology area. In addition, this method can help high management to make a right decision making by proposed the worth segment they should focus on.

Innovation in Action: Edupreneurers' Objectives and Practices for Quality Education

Shaista Khalid[1], Zubair Ahmed Shah[2], Mirza Ashfaq Ahmed[3]
1 Department of Education, University of Sargodha
2 Principal, Quaid e Azam Academy for Educational Development, Sargodha
3 Department of Management Sciences University of Gujrat
(E-mail: shaistakhalid@uos.edu.pk, zashah101@gmail.com, ashfaq.ahmed@uog.edu.pk)

Abstract: Present study aimed to explore the mission statements of schools and intentions of edupreneurs in relation with their practices toward quality of education they are imparting. Objectives of the study were to find out the mission statements and practices of private edupreneurs and to compare it with the perceptions of parents and teachers about quality of education claimed by the schools. Qualitative research design was opted for the study and using purposive sampling technique seventeen edupreneurs running well reputed private schools in cities of Sargodha, Lahore and Gujrat were taken as sample. Teachers (N 26) from these schools and parents (N 19) as stake holders were also the part of sample. Document analysis, Semi structured Interviews of the owners and principals of schools and focus group interviews of parents were conducted to gather the data for the study. Three indicators of quality i.e. input, process and product were studied. Thematic and content analysis of data revealed that majority of the mission statements of schools had included community service, innovative ways to impart education, to increase quality of education, to develop leadership qualities among students, as their major targets. There were no defined ways established by the schools to assess the achievement of school targets. Majority of the teachers and parents reported earning money as the major focus of the school administration in contrast with the mission statements of schools which spoke of innovation and quality education as the first priority. Parents perceived high fee structure and load of foreign text books as the major indicator of quality of education. The findings indicated discrepancies between the passion and practices of edupreneures. Findings also highlighted general perception of the society where schools with high fee structures are reputed as status symbol in society and are equalized with quality education. Research findings may be implied by adding the element of accountability to check balance between the intentions and practices of edupreneurers. Future research might investigate the mission statements and practices for quality education by using mixed method research design applied to larger sample.
Key words: Edupreneurers; Private schools; Mission statement; Quality education; Stake holders

1 Introduction

Edupreneureship is comparatively a new concept in Pakistan. Edupreneur, According to the International Academy for Educational Entrepreneurship, equals educational entrepreneurship. To some other organizations edupreneurs are grouped in the category of social entrepreneurship. As a concept, Edupreneurship means enterprise of any entrepreneur in educational filed (Vivek&Upadhyaya ,2015).

The notion of Edupreneur can be best understood by locating the development of its root word entrepreneur.   Literature review reveals that Richard Cantilton, an Irish partisan economist invented the word "entrepreneur" in 1730 (Casson, 1990). Webster dictionary defines entrepreneur as, "a person who organizes and manages an enterprise with considerable risks[1]". Thus Edupreneurscan be considered as educational entrepreneurs who are able to plan, establish and effectively run educational institutions. In this endeavor edupreneurs handle lawful and unlawful obstacles with unwavering risks management skills. The enterprise created by an edupreneur can aim at earning profit or it can be of non-profit nature. But in order to get attention of people, edupreneurs keep their educational services updated. Generally, edupreneurs can be put into two categories: public and private. In literature many traits of Edupreneursare discussed: High Creativity, devotion to the purpose of education revolution; Disaster Manager, Technical knowledge; Multi-tasking;; Pedagogical Innovations; Micro level Management, Hurdle Jumper; Human Resources management, Self Guidance. Some other qualities of educational entrepreneurs affirm them as persistent, positive, creative, daring, tireless, willing to take risks, capable, independent, resourceful, and considerate.(Leisey& Charles, 2000). All the above stated traits contribute towards the build of edupreneure. However Self-motivation must be the essential desire for operating the enterprise (Vivek&Upadhyaya, 2015).   Edupreneures set their skills in action for the improvement

---

[1] https://www.merriam-webster.com

of prevailing system of education.

Education is considered the solution for problems of society. Public and private institutions continuously put their efforts to contribute in making the system of education better and effective for the development of society. For education of high quality to flourish, it is believed that entrepreneurism in education is the key to identifying and implementing those changes. Establishment of every new school is taken as a step toward betterment in education system. System is established keeping in view the objectives. Objectives can be reflected in mission statement of the institution and can be achieved through the implementation of activities based on the objectives. In other words it can be said that the school practices are a reflection of the mission of the school.

In recent years, the number of private schools has been increased rapidly. These schools are a commercial reply to encounter the imperative education need of the nation by growing access to the communal children (Meril, 2014). Edupreneurial enterprises are presently experiencing considerable growth worldwide. Educators aiming at profit have the ability to provide education which meets parental expectations. They are free to change the curriculum and teaching methods they wish to propose (Farrelly, 2005).

In order to retain and contest, schools have to struggle hard. They have to identify the goals and objectives, and in order to attain these aims, they have to adopt appropriate methods. Schools have to embrace such an approach that focuses on future and is ongoing (G üven ,20011). While formulating plans, an organization makes choices between different substitutes. An organization seeks guideline from mission statement in order to adopt appropriate strategies directed towards the attainment of goals. An organization builds its structure on its mission statement. A well thought and well written mission statement reveals the exact purpose of the organization. It also outlines its range of action in terms of products and markets.

Mission statements are distinct for the organizations from each other (Ülgen&Mirze, 2004). Mission statement outlines the goals, aims, and the strategic objectives of the organization (Tutar, 2004). Din çer (2004) opines that the mission states the commonly held organizational beliefs and values, and sets the long-term goals which are distinctive and unique. Mission also defines the quality criterion. With a stronger vision, organizations can easily anticipate the future and prepare themselves for change. Visionary organization face the future with courage, can foresee changing demands, and enhance their efficiency (G üven, 2011).

The diversity of private schools can be compared by comparing the vision and mission statements they have established for them. The mission statement of schools builds on those fundamental values which they wish to promote through education. The mission statement also guides the way educational programs are conducted. The governance structure of school is also guided by their mission statements. The mission statement is also starting point for how teaching and learning occurs in schools (Boerema, 2006).

Keeping in view the importance of mission statements and their role in keeping the practices aligned towards the achievement of goals, the present study was designed. The study aimed at exploring the points of innovation in terms of their aims and practices of well reputed private schools as an endeavor toward improvement of educational system.

2 Methodology

Qualitative research design was opted to deal the in depth nature of the problem.

2.1 Sample

The sample included owners/ principals (N 17) of well reputed private schools of Sargodha, Lahore and Gujrat; teachers (26) and parents (19). Purposive and convenience sampling technique assisted the researchers to take the sample from schools where the enrollment of students was higher than five hundred and the school administration consented to participate in the study.

2.2 Research instrument

Data were collected from the principals, teachers and parents using semi structured and focus group interviews respectively. The interview Questions were pilot tested and validated through experts' opinion. Initially fifteen questions were constructed and afterwards modified to 10 questions each for all the three groups of respondents.

3 Data Analysis

The interviews were recorded and transcribed. The data were exposed to content analysis and

thematic analysis. These are powerful techniques to make sense of qualitative transcriptions by identifying pattern hidden in in the text (Hodson, 1999).. Specifically, content analysis might be used to reveal group patterns, and institutional structures in the societies. It also reveals their thought patterns (Weber, 1990, p. 9).

The following section presents the samples of answers obtained from all the three groups of the respondents:

Q1 What is the mission statement of the school?

All school leaders declared that schools have mission statements placed either on the school gate, classwork copies, in principal office, or written on the inner side of the boundary walls.

The statements included number of goals. The major school goals mentioned in the statements were service to community, provision of quality education, all round development of students, development of leadership qualities among students.

Teachers: very few teachers were aware of the mission statement. However they responded that the school was working to achieve the goals of students' high performance in exams.

Parents: only a few educated parents (3) reported that school had learning as its major goal.

Q2 what is the action plan to achieve the set goals of school?

There were no written action plans available in schools. Majority of school heads reported that they are successful in the achievement of the set goals of the schools. It seems that action plans were inherited and observed verbally. There is no defined practice of making assessment of the achievement of the goals.

Principals

Case 3: "I share my goals and action plans with my team members but I do not need to write it."

Case 5: "I have action plan in my mind to achieve goal."

Case l 6: "We have been observing the same action plan for years, and we still follow it".

Teachers

Teachers reported that there was no written action plan shared by the school. However they were given time to time instructions by the administration about their classroom teaching and other duties.

Case 7: "I don't know what is the action plan of school but I get instructions from the coordinator in staff meetings and sometimes randomly to improve my teaching and classroom discipline"

Parents

Case 9: "I am also teaching here. I think school administration wants to show outstanding results in board exams and we have to work hard in the classrooms".

Case 13: I have no idea as I am only concerned with the study of my children. They have very heavy bags and we have to pay heavy fee too. School continues to charge through the year for different purposes".

Case 2: I think school administration wants to earn at first.

Q3 what are distinguished features of school?

Principals

Principals were asked to describe the salient features of the school which make it different from other contemporary schools. All respondents claimed that their schools were performing differently with particular distinguished features.

Case 2: "We are offering clean and neat environment."

Case 1: "Sports and co-curricular activities are our distinguished feature of this institution."

Case 10: "Teachers are well educated and professionally developed."

Case 3: "Homework checking and continuous testing"

Teachers

Case 7: teachers' continuous evaluation

Case 11: discipline and co-curricular activities

Parents

Case 5: study routine of children. School engages them all the day in homework

Q4 what are the facilities and infrastructure provided?

Principals

All the respondents claimed that they are providing all possible facilities to their students, e.g. drinking water,shelter, cycle stand, canteen etc. in case of infrastructure, building was sufficient including classrooms, washrooms etc.

Case 7: "my school has all classrooms separately for all classes"

Case 9: "well, I think all facilities are at their best."

Case 5: "we have building according to education department code."
Teachers

Case 1: classrooms are big and airy
Case 6: computer lab is available
Parents
Case 3: play ground is not available in the school
Case 8: fee is high but sufficient facilities are not provided
Q5 what skills teachers possess? The selection criteria; teachers training
Teachers were selected on need bases. Tests and interviews are two selection criteria for teacher selection. No scheduled training was reported by any head teacher.
Principals
Case 2: "Teachers become skilled when they encounter with class problems."
Case 3: "No such training is conducted for teachers."
Teachers
Case 7: "Sometimes micro teaching sessions are arranged."
Case 10: "teachers discuss their teaching problem with each other and resolve it"
Case 3: "demo sessions are arranged for selection of the teachers"
Parents
Most of the parents had no idea about the teachers' selection.
Case 9: "I think interview is major tool to select the teachers"
Q9 what is the fee structure? Is it justified?
Majority of selected schools have fee structure ranging from Rs 3000 to 4500 per month. Although an amount of Rs 13000 to 20000 was taken as security and admission fee.
Case 1: "Yes, fee is little bit higher than other schools but we are providing many facilities too."
Case 3: "I think it is appropriate."
Case 6: "we are serving the community and other expenditures are too high, so fee structure is appropriate."
Teachers
Case 2: fee is charged according to the services provided
Case 18: it is expensive for the middle class but many children come from business families or land owners.
Teachers' salary is not sufficient. Fee is hardly affordable for some of the parents. But facilities should be improved to match the fee charges.
Q 10 do you think the school is successful in its practices to achieve the targets mentioned in mission statement?
Principals
Case 2: yes we practice the same as we have mentioned in our mission.
Case 4: yes sure. My team works hard and they make it possible.
Case 17: we achieved our target last year our student got outstanding position in board exam.
Teachers
Case 6: I don't know about the mission statement but we make our best in classroom.
Case 10: yes our students get position in board exam every year.
Parents
Case 3: I don't know the school targets but children have no time to do other activities. I am happy because they get busy whole day

4 Discussion

This study explored the mission statements prepared by schools to represent the ideas and hopes of what they want their school to be. The analysis provides an insight into what is the target and intentions of the people that make up and lead schools.   It is found that majority of edupreneurs had either no mission statement or it was not documented. Without a statement that reflects the intentions of the school leaders, it is difficult to understand how a mission can appear in practice. The mission statement is the necessary condition for many different individuals to pull together through numerous activities to achieve central shared purposes. (Jack Meacham 2006). Witten plans of actions were also absent and teachers were directed verbally to perform various tasks and duties. Majority of parents had no idea of

targets of school. It is usual in our society where parents are less educated.

The analysis revealed that edupreneurs had some targets in common as community service, provision of quality education, and development of students as future leaders. However the salient features which were reported by the respondents as unique, were shared by all the schools in sample.

5 Conclusion

The study concludes that there is a gap between the mission statements and the practices of schools. The obvious reason is the absence of any written and chalked out plans to put forth the objectives into actions. There was also difference in parents' response about the mission of schools. Parents reported the money making as priority of the schools as compared to the edupreneurs' statements who declared the provision of quality education at their first.

On the bases of conclusion, it is recommended to device an assessment procedure to evaluate the mission statements of the edupreneurs against their practices.

Accountability of every school business is also needed to promise the provision of appropriate facilities and services against the fee structure of the school.

Further research is needed to determine the degree to which the variety of goals expressed in the vision statements are carried out by the schools.

The future research may include all types of schools from the community to have more clear view of the problem.

(E-mail: andrii.dryga@gmail.com, mariiavaliavko@gmail.com)

Abstract: Grants management serves to address and to monitor the utilization of aid from international and domestic donors to beneficiaries, such as non-governmental organizations. Nowadays grants management faces many challenges, and the deployment of innovative technologies serves to prevail over them. The paper focuses on the potential effects of the implementation of blockchain technology in the grants management process. The article employs the study of literature on current problems that exist in the grants management field, and a critical assessment of the frequently exaggerated benefits and capabilities of blockchain technology. The paper also discusses the possible implications of blockchain for non-governmental organizations and processes. The paper draws a conclusion that blockchain has potentials to provide solutions to many current challenges in grants management.
Key words: Grants management; Non-government organizations; Donor organizations; Innovation management; Blockchain technology

1 Introduction

The role of non-governmental organizations (NGOs) as agents of change in providing social services and aid to people and communities in need is extremely high. The existence of challenges in grants management process, which could have negative effects on operations, management, and financial support of NGO, makes a call for research on conquering those issues.

Many scholars addressed their studies to explore and to provide some insights on existing challenges of grans management and NGO in particular (Rahman & Sawada, 2012; Bhushan & Bond, 2013; Gent, et al., 2015; Gloria, et al., 2017; Nazuk & Shabbir, 2018). Others were trying to connect the capabilities of blockchain technology in different managerial and business fields (Gebert, 2017; Beck & Müller-Bloch, 2017; Turk & Klinc, 2017). Though, there is a research gap in discovering the potentials of blockchain technology in regard to the main challenges of NGOs' grants management.

2 Grants Management in NGOs

A non-governmental organization is a non-profit, volunteers-based group, not related to the governmental institutions. NGOs are organized on local, national and international levels to serve specific purposes according to their objectives. Grants management, as a part of fundraising expenditures management (Herzer & Nunnenkamp, 2013), plays a vital role in the existence of NGOs. Grants management is defined as a process in which one agency (donor) distributes funds to other organization (grantee), in order to achieve concrete social goals (Weiss, 1973). NGOs receive grants, which generally are not refunded fundings, to implement social projects with clearly defined objectives in a specific country or region (Rus, 2015).

Figure 1 shows NGO as a grantee and its most important stakeholder groups: the donors (the general public, governments, and charities) and the recipients (governments, communities, social entrepreneurs, households) (Linders, 2013; van den Broek, et al., 2012). NGOs can gain funding that does not need to be repaid by submitting applications for grants.
Figure 1   Overview of the Development Chain
Adapted from (van den Broek, Rijken & van Oort, 2012)

Donors initiate a call for project proposals and announce specific requirements for applicants and their projects. An applicant becomes a grantee after it has signed a grant agreement with a donor.

During the grants management process, donors and grantees face various challenges.

2.1 Challenges in grants management field

According to the Grand Bargain – A Shared Commitment report (IASC, 2016), 18 donor countries and 16 aid organizations (including UN entities, international NGOs, and the Red Cross Movement) have stated ten major priorities to address existing challenges in the non-governmental sector. Four of these priorities are related to grants management field; (1) an increase of transparency, (2) an increase of effective and efficient procedures for reporting, (3) an increase of recipients' institutional capacities, (4) a decrease of management costs.

3 Blockchain Technology

Since it was first introduced (Nakamoto, 2008), a blockchain has become one of the most trending technology in the last decade (Risius & Spohrer, 2017). Numerous projects with implementations of blockchain technology outside the financial field are still rather experimental (Kshetri, 2018). Nevertheless, due to its innovative characteristics, a blockchain technology has the potential to change existing managerial paradigms and to provide new insights into the existing issues and challenges.

Blockchain can be defined as a decentralized, encrypted, distributed database, which maintains information that cannot be reversed or corrupted (Wright & De Filippi, 2015). A Blockchain is also known as a distributed public ledger (Crosby, et al., 2016) -- a database of records of every transaction that has been happened within the network (Morabito, 2017), and shared among all participants of this network.

Some authors propose the vision that the blockchain technology introduces new ways and models of business and organizational development with virtual organizations and automatic business operations (Tapscott & Tapscott, 2017; Puschmann & Alt, 2016). Others pointed out that it is necessary to understand how organizations could benefit from the technology, and how to be sure that all stakeholders on all levels are ready to change, adapt and adopt the innovation (Beck & Müller-Bloch, 2017; Morabito, 2017). Therefore, some scholars and practitioners suggest (Beck, et al., 2017) to analyze the blockchain technology from a more critical perspective.

As a technology, blockchain is a chain of blocks which contains records and timestamps. Each block is identified by its cryptographic hash (Christidis & Devetsikiotis, 2016). Each block references the hash of the block that came before it (Fig. 2).
Figure 2　The Simplified Model of the Blockchain Adapted From (Christidis & Devetsikiotis, 2016)

The main technical characteristics (Christidis & Devetsikiotis, 2016; Glaser, 2017) of a blockchain technology are:

a.the entire chain is duplicated among all participants (so-called nodes of the peer-to-peer network);

b.after assigning into the chain data become irreversible;

c.the use of smart contracts, automatic execution of transactions if both exchange parties meet specific pre-defined criteria (Hinings, et al., 2018), is allowed;

d.each transaction is protected by powerful cryptographical algorithms;

e.the network is decentralized.

Due to those technical advantages, a blockchain technology provides features which correspond to the needs of grants management:

a.blockchain keeps the history of all transactions and related metadata, including time and author's information, which ensures the transparency of all operations and organizations itself;

b.decentralization of the network means that it does not require the approvement of transactions or its own legibility from the third party or centralized authority;

c.information management facilitates the peer-to-peer collaboration of companies, individuals, and other stakeholders.

3.1 Blockchain technology in the grants management field

Despite the fact that blockchain technology was invented as a tool to prevent double-spending during the cryptocurrencies transactions, it has been applied in various fields of business and management: supply chain management (Kshetri, 2018; Feng, 2016), service management (Price, 2015), healthcare (Ekblaw, et al., 2016) and others.

For now, the usage of blockchain in grants management has been limited. Some scholars state that it is still hard to find empirical evidence to illustrate the appropriate use of blockchain technology (Wang, et al., 2016). Others suggest using blockchain-based projects for crowdfunding purposes (Gebert, 2017; Glaser, 2017). Crowdfunding and grants management are both related to fundraising, however, the first one operates on an individual level, and the other one – on organizational.

Based on the Great Bargain report (IASC, 2016), donors search for innovative technologic projects that can significantly improve the operation of non-governmental organizations. Although, specific solutions on this matter are still under development.

4 Major Potentials of Leveraging Blockchain-Based Solutions to Improve Grants Management Field in NGOs

The following analysis illustrates the possible capabilities of solutions based on the blockchain technology aimed to improve grants management process of NGOs in the following aspects:

4.1 Increase of transparency

The lack of transparency, openness, and accountability of NGOs are ones of the permanent challenges of the field (Burger & Owens, 2010; Keating & Thrandardottir, 2017). Some initiatives were implemented to improve the status quo of the open data leveraging. The International Aid Transparency Initiative (IATI) was introduced to increase transparency during the grants management process. Still, the stakeholders of the IATI have some concerns in regard to its technical, financial, privacy and legal issues. (Bhushan & Bond, 2013). In the Grand Bargain report (IASC, 2016) it was proposed to deploy a joint digital platform with an implementation of open data technologies, which "provides an opportunity to publish funding moves from donors to recipients in a timely, harmonized, and transparent manner".

As it was mentioned before, due to its technical characteristics, blockchain technology provides a high level of transactional transparency (Birch & Parulava, 2018). The grantee has a possibility to publish on its organization's blockchain system transparent, harmonized and high-quality project data, which corresponds to the International Aid Transparency Initiative (IATI) standards.

As a result, donors that receive an access to the blockchain system of a grantee organization, are able to assess the cost-effectiveness of previous projects. Moreover, the system demonstrates how funding moves from donors down the transaction chain until it reaches the final responders.

4.2 Costs reduction and simplification of the reporting process

The next important issue is an effectiveness and an efficiency of the reporting procedure. Due to various reasons, donors' reporting requirements have grown significantly over the past years (IASC, 2016). However, costs of the required reporting are able to cover only organizations with strong institutional capacity. The innovative technology is able to reduce these costs through total or partial elimination of middleman services, such as annual audits.

Based on its decentralized architecture, the blockchain technology eliminates the need for the approvement of its transactions legibility by the third party or centralized authority (Morabito, 2017; Freund, 2018). It has a capability to provide an opportunity to a grant-giver to approve reliability and quality of grant-receiver project reports published on the blockchain system through personalized donor signature. In other words, after grantee has published its financial and activity reports in the system, the donor signs these reports.

Thus, if all projects' reports are verified by grant-givers, there is no need to use middleman services to prove grant-receivers' reliability.

4.3 Reduction of duplication and management costs of a donor

The international aid community and the aid recipients are diverse, and very often the presence of a large number of donors and projects overwhelms the recipient's capacity to manage and administer aid inflows efficiently (Rahman & Sawada, 2012). Thus, one of the biggest challenges in a grants management process is a reduction of duplication and management costs by donor coordination. Shared assessment of information, financial monitoring, and performance reviews among donors help to avoid duplication and to reduce management costs (IASC, 2016).

From an information managemental prospective, the peer-to-peer collaboration of all stakeholders

brings a potential for the blockchain technology to eliminate a duplication of information (Morabito, 2017; Beck, Avital, Rossi & Thatcher, 2017), and to save operational and management costs.

Hence, donors are able to use assessment information, provided by the previous grant-giver to an applicant, directly from a blockchain-based solution, without additional usage of time or finance.

4.4 The increase of the institutional capacity of a grantee

The Grand Bargain states "donors should support local and national grantees through the increase of investment in their preparedness, response and coordination capacities" (IASC, 2016).

Due to its transparency and trustworthy characteristics (Crosby, Nachiappan, Pattanayak, Verma & Kalyanaraman, 2016) blockchain technology has potential to increase the institutional capacity of grantees by decreasing operational costs of each submission process. Blockchain provides an opportunity for an applicant to publish its portfolio of projects on the blockchain-based system.

In nutshell, an organization can increase its capabilities by a decrease of its administrative costs during submission of a project proposal by minimizing expenses connected with a preparation of administrative documents, among which are references from previous donors, audit reports, public registration forms.

5 Conclusion

The study of the literature review shows that world-known donor organizations are ready to invest in innovative technological solutions for the grant management process. We conclude that the blockchain technology has potential to become an appropriate solution for addressing such challenges of grants management as (1) an increase of projects and organizations transparency, (2) a decrease or elimination of the role of audit companies as middleman services, (3) a reduction of operational and management costs, and (4) an increase of organizational capacity.

Further research should sophisticatedly consider how blockchain technology innovation is applicable in regard to each of the grant management challenges, and how all stakeholders are ready to accept it.

Abstract: With the development and progress of science and technology, innovation has become the decisive factor in promoting regional and national economic development. After analyzing the research all over the world, this paper based on the current situation of building an innovative city in Wuhan to accelerate the pace of its constructionand improve its regional competitiveness by focusing on scientific research, carrying out all-round innovation and creating a central university innovative economic circle,in order to explore a reasonable way for Wuhan to build an innovative city.
Key words: Measure; Innovative city; Wuhan; All-round innovation

1 Introduction

Innovation is the core competitiveness of a region (Tao F Y, 2011). There is a lot of research all over the world. Cooke P, Uranga M G and Etxebarria G developed the concept of regional systems of innovation. They related it to preexisting research on national systems of innovation (Cooke P, 1998). Boschma R A researched the impact of globalization on the regional and local conditions for innovative activities and assessment of the interaction of regional and national innovation policy (Boschma R A, 2005). Uyarra E said the impact of universities on the innovative potential of regions has been the object of intense scholarly and policy interest in the last years (Uyarra E, 2008). JY Song, GE Chao-Yang and J Chen defined the connotation of original innovation in basic research, and pointed out some critical problems in evaluation of original innovation of basic research sources (JY Song, 2004). Xu Qingrui, JiaFuhui, XieZhangshu and Zheng Gang elaborated the connotation and characteristics of the all-involvement innovation based on the theoretical framework of all-round innovation (Xu Qingrui, 2003). Etzkowitz and Leydesdorff further raised the Triple Helix of University-Industry-Government Relations into a model for studying knowledge-based economies (Leydesdorff, 2013). There are many cities around the world are building innovative cities such as London, New York, Daejeon, Beijing, Shenzhen, Shanghai and Nanjing,etc.From this point of view, it is inevitable to create an innovationcity. City innovation is a kind of regional innovation,in the process of city development, innovation is the driving force, constantly integrating new ideas and concepts to promote the economic development of the city. Wuhan, as a major city of science and education in central China, it is a mission to drive innovation and development in the region of the Yangtze River Economic Belt and promote national technological innovation.

2 The Current Situation of Building an Innovative City in Wuhan

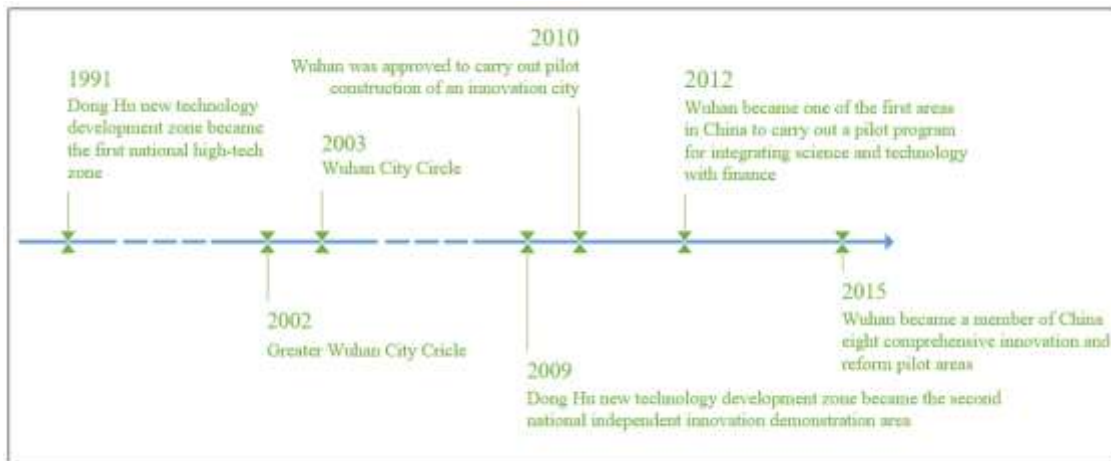
The science and education resources are abundant in Wuhan. At present, there are 84 universities and the number of colleges ranks second in China. There are 1.075 million undergraduates (including postgraduates), which is the largest number of college students in China. The scientific and technological strength is strong. It has 31 national laboratories and national key laboratories. The number of patent application and authorization shows a good growth. Figure 1 shows the trend of patent application and authorization in Wuhan in the past five years. The competitive industries of Wuhan are also outstanding, including the new generation of information technology industry, life health industry and intelligent manufacturing industry. In addition, the strategy of "promoting the rise of the central region" and the policy of "1+9" have accelerated the pace of Wuhan's construction of an innovative city. Wuhan follows the pace of building an innovative country to build an innovative city.Figure 2 shows the development of innovation in Wuhan.In 1991, Dong Hu new technology development zone became the first national high-tech zone.In 2003, Wuhan decided to create the "Wuhan City Circle" on the basis of the "Greater Wuhan City Circle" in 2002. In 2009, Dong Hu new technology development zone became the second national independent innovation demonstration area. In 2010, Wuhan was approved to carry out pilot construction of an innovative city. In 2012, Wuhan became one of the first areas in China to carry out a pilot program for integrating science and technology with finance. In 2015, Wuhan became a member of China eight comprehensive innovation and reform pilot areas and assumed the responsibility of taking the lead.
Figure 1   The Trend of Patent Application and Authorization in Wuhan


Figure 2   The Development of Innovation in Wuhan

3 Countermeasures and Suggestions for Building an Innovative City

3.1 Focus on scientific research

We are devoted to making Wuhan an innovation city where innovation activities are intensive, innovation products are enriched, and innovative enterprises are clustered bystrengthening basic research and exploring future industries.

3.1.1 Strengthen basic research

The source of innovation mainly lies in basic research (Chen Jiaer, 2005). The construction of the innovative city must strengthen basic research and strengthen the supply of innovative sources.Focusing on the strategic needs of innovation and development in Wuhan, we will focus on strengthening the application basic research of the application of electronics and communications equipment manufacturing and pharmaceutical manufacturing (as shown in Table 1),obtain a batch of significant original innovation achievements to consolidate Wuhan's leading position and influence in basic research in related fields.The research universities are the main force of basic research(Liang Tong, 2005), it is necessary to take advantage of the talents of a research university to establish a complete talent training sequence from bachelors, masters, doctors andpost doctorates to postdoctoral studies, and actively cultivate and establish high-quality research teams;making use of the subjects advantages of research universities to exert the strong discipline of each university and strengthen the frontier research in this field;Wuhan should strengthen protection of intellectual property, increase the rewards for scientific research, and encourage innovation and creation.

Table 1   The Industry and Field of Innovation

Innovation industry	Basic research field
Pharmaceutical manufacturing	Surrounding cytology, biological modeling, biomaterials, particle jet deposition, nanotechnology, gene editing, etc.
Electronics and communications equipment manufacturing	On-chip photonics and electronics seamless integration technology, micro-sodium photonics, communications, information processing and data storage technology, advanced photonics measurement and application, strategic optical materials, display technology, quantum computing and other fields.

3.1.2 Explore future industries

To seize the heights of future industries and explore future industries, there are 12 potential industries to create a city for industrial innovation, including electronic information and internet industry, financial industry, energy and resource industry, modern agriculture, advanced manufacturing, cultural industry, large health care industry, pension industry, the modern logistics industry, education industry, environmental protection industry, and large tourism industry.

(1) Competition is the competition between time and speed. We should take action early and keep an eye on the development of the industry and improve the competitiveness of Wuhan's future industry;

(2) Seize the opportunity, aim at the development direction of the unopened industries, and win the opportunity;

(3) Strong and strong alliance, combining the industry developed areas and enterprises to improve the overall capacity.

3.2 Carry out all-round innovation

The all-round innovation aims to build an innovation and entrepreneurship ecosystem through all-object innovation, all-domain innovation, all-industry-chain innovation, and all-involvement innovation.

3.2.1All-object innovation

Focusing on the products, processes, organizations, markets, and resources to promote all-object innovation in Wuhan.

Products: actively introduce advanced technologies and products, imitate innovative thinking and methods, grasp core technologies and secrets, combining the actual conditions of Wuhan to develop and improve self-innovation capabilities.

Process: using the new technology or the original technological advantages in the society to carry out process innovation underthe market demand of Wuhan.

Organizations: reduce the level of intermediate organization, build the partnership between leaders and employees, pay attention to the training of employees' knowledge skills, and strengthen the flow and sharing of information and knowledge.

Markets: explore new markets, expanding the products of Wuhan to unprecedented new markets, expand overseas and rural areas; develop new products based on consumer need and potential need.

Resources: according to the material, human, and financial resources owned by Wuhan, it provides a guarantee for innovation.

3.2.2All-domain innovation

Cultivate and build a number of innovative towns, and innovative neighborhoods to promote all-domain innovation in Wuhan. Specific measures include:

Based on the "Guidelines for the Construction of Innovative Cities" Wuhan should strengthen the achievements and experience that it has gained in the pilot construction areas of the nation's innovative cities.

Further implement the "Guiding Opinions of the Provincial People's Government on Accelerating the Planning and Construction of Featured Small Towns" and accelerate the creation of a number of innovative towns in Wuhan.

A number of innovative neighborhoods have been built in urban centers and high-density urban areas with high density crowds,convenient traffic, developed communication networks, high corporate concentration, and frequent economic activities.

3.2.3All-industry-chain innovation

Focusing on Wuhan's new generation of information technology, high-end equipment and materials, biotechnology,green and low-carbon, new energy vehicles, digital creative and other strategic emerging industries and major traditional industries, improve its industrial chain and promote Wuhan's all-industry-chain innovation.

Overall consideration, integrated development.For the major industrial chains, we will focus on the weaknesses and key links in the industry chains, promote the integration development of various industries, make up for shortcomings in industrial development, and focus on cultivating industrial advantages, product advantages, and competitive advantages with lasting competitiveness.

Diversified development, collaborative development. Using the guiding role of fiscal funds to support various innovation models in the industry, mobilize enthusiasm, participate in the development of the entire industry chain, and promote the organic convergence of all links in the industry chain and share the development results.

Clear penalties, stimulate competition. In accordance with the requirements of "openness, fairness, and fairness", we should improve the mechanisms for competition establishment, and select the best. Strengthen the management of performance appraisal, improve reward and punishment policies, strengthen the supervision of the process, and continuously increase the use of funds.

3.2.4 All-involvement innovation

All-involvement innovation is the foundation of science and technology innovation. It is an important part of the people's scientific and technological innovation work. It is an important way of bringing the enthusiasm and creativity of the general staff to Wuhan's innovation and development. Specific measures include:

Improve quality and lay a solid foundation. Efforts should be made to change the people's ideas, and set up the concept of "innovation can be done in every way and all people can do it (Ren Huijuan, 2010)"; stimulate innovation enthusiasm, foster innovation ability, and continuously improve the innovation and creation ability of the people.

Build carriers and carry out effectively. Find small problems in daily life and propose small innovations; build an information sharing carrier, create an innovative atmosphere, establish an online sharing platform for innovation results, broaden the horizon, achieve the results sharing, and facilitate communication.

Improve the mechanism and advance in an orderly way. Establish and improve the standard management mechanism and promote the standardization of activities; strengthen the incentive mechanism, fully mobilize the initiative of the people's initiative innovation, and continuous innovation.

3.3 Create a central university innovative economic circle

Improving the ability of independent innovation is the key to building an innovative country (Shang Y, 2005). High level of scientific research and technological capability is the source of independent innovation. A comprehensive research university is responsible for this policy and shoulders the important mission of building an innovative country. In order to speed up the building of an innovation city in Wuhan and achieve integration of production, innovation, city, education, and research, it is necessary to build a central university innovative economic circle, such as central university innovation economic circle of East Lake and South Lake. There are some measures to create a central university innovative economic circle:

(1) Through a variety of platforms, and expand the transverse connection and resource integration of university in economic circles, realize the resources of the library, the selection of minor courses across campuses, the opening of laboratories to integrate various universities' internal resources, in order to realize the sharing of resources;

(2) We will optimize the surrounding environment of universities, and plan bases for innovation and entrepreneurship around the universities, including innovation and entrepreneurship parks, science parks, incubators, etc.

(3) To establish the management committee of the central university innovative economic circle, which is responsible for the management, coordination, guidance and promotion of the economic circle;

(4) To establish the resource sharing mechanism of the campus, in the central university innovative economic circle, "the city is the school's city, the school is the city's school", and the people interact and share resources.

4 Conclusion

It has become a trend to build an innovation-oriented country, and it is necessary for Wuhan to build an innovative city. This paper puts forward some suggestions for the construction of the innovation city of Wuhan based on the research all over the world: focus on scientific research, carry out all-round innovation, and create a central university innovative economic circle.However, due to my limited ability and subjective ideas, I cannot put forward more comprehensively propose countermeasures. For

example, talents are very important for the construction of innovative cities. There are many universities in Wuhan, but the problem of brain drain is still serious. It is necessary to propose an effective solution to this problem, and we need further exploration and optimization.

Research on the Mobike Business Mode Innovation under Internet Environment

Sun Yumeng, Cheng Yanxia
School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: 1257648677@qq.com, chengyanxia221@126.com)

Abstract: The traditional business mode has been unable to adapt to the development of the Internet society. The business mode innovation of service companies has become the key to the sustainable development of the company. Mobikes have become the benchmark of innovation for modern service companies. The paper drew on existing research results, used factor analysis methods, and combines Mobike's innovative commercial modes to study the key elements of the business mode in the Internet environment. Simultaneously, it proposes suggestions and countermeasures for the Mobike business mode innovation.
Key words: Mobike; Business mode innovation; Key elements; Service industry

1 Introduction

With the growing global economy, the service economy will become the dominant force in world economic growth. With the rapid development of Internet technology, the traditional service industry is no longer adapted to the existing economy, and reforms are imminent. In particular, business mode innovation has become a key to the "breakthrough" of traditional service industries. Mobike is a typical case of success in the traditional service industry through business mode innovation under the Internet environment. The success of Mobike's business mode demonstrates that traditional service industries must adapt to the requirements of the Internet environment and their business modes must be compatible with this environment to be sustainable.

Extant literature has rich research on the constituent elements of the business mode. Whitehurst (Whitehurst, 2002) believes that a business mode includes four elements: customer interface, core strategy, strategic resources, and value network. Johnson and Christensen (Johnson and Christensen, 2008) proposed that business modes comprised of four elements: customer value propositions, profitability modes, key resources, and key processes. While, Osterwalder et al. (While, Osterwalder et al., 2005; 2011) revealed that a business mode contains nine essential elements: value proposition, customer segmentation, distribution channel, customer relationship, source of income (or income approach), core resources and capabilities, key business, and important Partner and cost structure. Besides, Huarng (Huarng, 2013) anticipated that the business mode consists of seven elements: innovation content, market positioning, value source, resource integration, cost, income, and profit. Alternatively, scholars like Zhang Yue and Zhao Shukuan (Zhang Yue and Zhao Shukuan, 2014) demonstrated that the business mode should consists of five elements: core product, target market, operation process, value distribution principle, and value chain structure. Further, Sheng Ya (Sheng Ya, 2015) puts forward the value proposition, value network, key resources, and profit mode as the core elements of the business mode. Most recently, Guo Shouting (Guo Shouting, 2016) proposed that the said mode encompass the value creation, value proposition, value transmission, and value realization.

2 Mobike Case Analysis

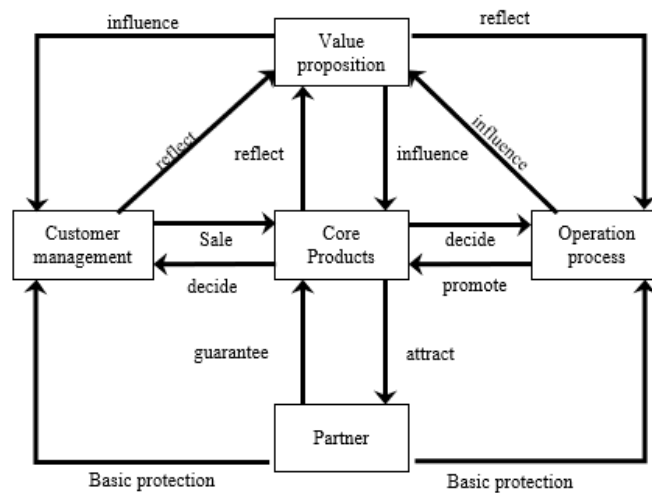
This article draws on existing research results and, through an in-depth analysis of the Mobike case, believes that the business mode consists of five key elements: value proposition, core product, customer management, operational processes, and partners. Its key performance is that these five elements have an irreplaceable role in the company's production materials in the process of enterprise creation of value, and there is a strong interaction between these five elements, and this interaction affects the relationship Value creation.


Figure 1   Business Diagram of the Key Elements of the Business Model

2.1 Value proposition

Value proposition refers to the value that a company can provide to its consumers through products and services. Broadly, it can be divided into economic value and social value. The value proposition is the dominant element of the five key elements of the business mode and serves as base for the formulation of other elements.

Mobike also reflected its value proposition in both, the economic value and the social value. In terms of economic value, the operation of Mobike conveys the concept of sharing economy, that is, "people need the value of products rather than the products themselves," and Mobike's bicycles adopt a "heavy assets and light operation" approach. In comparison to Didi and Uber which are typical "Internet+" company, Mobikes are more like service manufacturing companies, with manufacturing as their core and Internet technology. Compared with the traditional sharing economy mode, Mobi's self-supported mode is more conducive to the standardized management of products.

In terms of social value, Mobikes also have many advantages that other Internet projects do not have. One is the government's strong support and development. As a non-pollution and convenient travel mode, Mobikes not only respond to the national policy of energy conservation and emission reduction, but also protect the environment. Second, Mobikes have natural moral advantages. Different from the Internet field, such as online games, Mobike's main green travels have a natural moral advantage. Mobike cyclists explored a new blue ocean more. The Mobike cycle operation mode and the attributes of the bicycle itself are in line with the national environmental protection strategy, bringing great social value to the entire society. This has provided references for the development of other Internet companies and responded to the call of the world to protect the environment.

2.2 Core products

The core products include products and services that can effectively export to the target market and reflect the company's core capabilities. The core product is the bridge between the product platform and the platform product. It is the solidified carrier of the core competitiveness and the concrete demonstration of the value of the business platform. As the core elements of the business mode, the core product influences and restricts other factors. It is the most important carrier of value proposition and is the basis of the business mode innovation.

The concept of Mobike's product design is based on low-cost operation and environmental protection. It is an efficient use of resources and an unprecedented innovation. Transforming traditional products through new technologies and changing consumption patterns to enhance consumer experience. Mobike's bicycles are based on "Mobike shared bicycles" and are based on mobile apps and smart hardware. Mobike's first smart shared bicycle mode in the world, its patented smart lock developed in-house integrates GPS and communication modules, and uses a new generation of Internet of Things technology to enable users to locate and use the nearest Mobike bikes anywhere, anytime through smartphone apps. When the bicycle reaches the destination, it is parked in the right area near the roadside. At the same time, Mobike's APP has accumulated a huge amount of user data. In the future, the core competitiveness of the development of artificial intelligence is data competition. Whoever can

master large amounts of data will have strong competitiveness, that is, it will enter the IT age of the Internet. In the DT era, Mobike bicycles are undoubtedly competitive.

2.3 Customer management

Customer management is divided into two aspects: the division of the target market and the management of customer relationships. Customer segmentation refers to the group of consumers targeted by the company after market segmentation. The customer relationship, that is, clarifying the relationship established between the company and its customers, is mainly information communication feedback. Customer management is the basis of the business mode. Other elements are formulated according to different customer management. The value proposition guides the overall requirements of the customer. At the same time, the customer's choice also embodies the value proposition. The target customers are divided according to the core products and promote the improvement of the core products. Mobikes are mainly for first-tier cities. The high mobility, population density, and urban functional zoning of first-tier cities have brought a huge demand for commuting. Mobikes mainly cater to short-distance users within 3 kilometers and users who have temporary car needs. Mobike vehicles parked without fixed car piles, which gives users a great freedom of travel, but also attracted many users with temporary car demand.

2.4 Operation process

The operation process of an enterprise includes the organizational structure, business process, and the implementation and management of business activities. It is a prerequisite for the smooth development of an enterprise. The operation process meets the requirements of the value proposition, and at the same time, the core products are diversified according to different customer management.

Mobike's innovations also lie in the migration of mobile Internet technologies to traditional public bicycle rental businesses. The entire use process is implemented through the Internet. Users do not have to go to the offline service point to apply for a car rental card. They only need to download the "Mobike" APP to register and pay a deposit of 299 Yuan and carry out real name certification. From finding a car, approximating a car, driving a car, using a car, locking a car, and paying for the last payment can all be done on one app. This is in line with people's habits in the mobile Internet era, which greatly simplifies the circulation and reduces the usage threshold.

2.5 Partners

Partners refer to the value chain structure of an enterprise, including upstream and downstream partnerships, customer relationships, internal value chain structure, and external cooperation relationships. Partners are the strong guarantees and support for the smooth implementation of other key elements. The integration of upstream and downstream resources and internal and external resources will promote the smooth development of the entire business mode.

In cooperation with upstream and downstream, Mobike will integrate upstream and downstream resources. To the upper reaches, Mobike bicycles will use bicycles to modify and upgrade traditional bikes with new technologies, and become Mobikes that meet the standards. This will reduce the excess capacity to some extent. As a result of pressure from manufacturing companies to "destock", the market's bargaining power of enterprises has been greatly enhanced, and the development of manufacturing companies has been promoted from the side. At the same time, "de-capacity, clear inventory" has also become an important goal of national strategic development. The leasing industry can use excess production capacity for rental, and use the new consumer industry to revitalize inventory, which has become an important force for capacity reduction. To the downstream, the user is given the right to choose their own right. The user can select the location of the car, the location of the transfer, the time of the car, etc., while saving the user the cost of buying a car, repairing the car, and depreciating, saving the user time. And integrate these demand users into the APP, forming a huge data network, and gaining advantages for further development.

In cooperation with financing providers, Mobike developed rapidly and completed multiple rounds of financing within one year: In 2015, Yueyue Capital completed a multi-million dollars A round; in late-2016, Panda Capital led the investment, and Pleasant Capital invested tens of millions of dollars; B After the round, Mobai quickly gained B+ investment in innovation workshops; in January 2017, it received D-round financing of US$215 million led by Tencent and Warburg Pincus. After the financing of 215 million U.S. dollars was completed, the status of Mobike was basically locked in from the perspective of capital, and Mobike became the leader in the field of shared bicycles.

In cooperation with the government, Mobike responded positively to the national environmental strategy and was committed to reducing carbon emissions and traffic congestion. It has received strong support from the country, and Mobikeshave cooperated with the government to make fun of the "prohibition of

electricity and electricity restrictions" policy introduced by many municipal governments. A good mode, won the support of the community.

3 Discussion on Innovation and Improvement of Mobike Business Mode
3.1 Improve the credit mechanism
The lack of a credit system is undoubtedly the biggest obstacle to the current sharing of bicycles. In order to regulate the use of bicycles by users, after launching the "Credit Points" mechanism, Mobike's bicycles have also entered into cooperation with Qianhai Credit Co., which means that Mobicycle's user credit data will be included in the personal credit system of Qianhai Credit. Become part of personal credit. It can be described as a small step forward for Mobike to improve its credit mechanism. In the future, Mobike's credit scoring system can be considered linked to the government-promoted social credit system and other financial systems to cultivate the awareness and habits of users of civilized vehicles. On the one hand, information asymmetry can be reduced by sharing personal credit data with government regulators; on the other hand, the increase in default costs - the violation of the use of Mobike's actions on credit records may lead to individuals being unable to access finance. Services will have a stronger binding on users. By promoting the establishment of the entire social credit system and economic order, it will be able to provide a better soil for the continued operation of the sharing economy enterprises such as Mobike [11].

3.2 Government-enterprise cooperation supply mode
Mobike use private capital to enter the public transport field. They try to solve the problems of urban public bicycle development based on technological and organizational changes and market forces. However, under the purely private supply mode, the company is responsible for its own profits and losses and the risk is too great. In contrast, the pattern of government-enterprise cooperation allows companies to obtain preferential policies. There are two forms of government-enterprise cooperation that can be referred to. The first is government subsidies. This is how Wuhan public bike projects take this approach. However, in addition to the direct investment of a small part of the financial subsidies, the government also grants the operator the right to operate advertising and other projects, and the company obtains funds for public bicycle projects through self-employment to realize balance of revenue and expenditure. Second, PPP mode of contractual contracting system, that is, government-funded purchase of enterprise services, the company responsible for the specific operations, the government mainly assumes policy leadership, support functions and supervision of its daily capital expenditures, in accordance with the evaluation of the quality of business services in accordance with the contract payment operations cost.

3.3 Explore diversified profit modes
Drawing on the experience of current shared bicycle projects that have already been completed at home and abroad, the future commercialization of Mobike can proceed from the following points. One is advertising revenue. At present, the main source of income for public bicycles is the rental of parking pile advertisements. For Mobike bicycles without a fixed vehicle pile, profit can be increased by transferring the advertising rights of the advertising media of the car body or implanting advertisements in the APP. In the APP, the form of pushing ads to realize cash is more diversified, such as pushing the surrounding restaurant discount information to the commuters during noon riding. The second is the development of derivative products and services. The rental of bicycles has obvious "tide effect". As Internet software, Mobike can use its platform scale to develop some derivative products and services to fill the gaps in operations outside peak hours and ensure the stickiness of the platform. The riding data accumulated by the user on the APP can also be entered into the deep service of the fitness field through monitoring, collection and analysis.

4 Conclusion
Business mode innovation is an important guarantee for the vitality of traditional service companies. The five basic elements of the business mode have their own status and roles, and they are mutually constrained and influenced. The innovation of the Mobike bicycle business mode has brought a lot of experience and inspiration to traditional service companies. It should be based on core products, launched around value proposition, and carry out all-round business mode innovation with the support of partners.

Mobike was born in the soil of the sharing economy and the development of the Internet, which has played a vital role in improving the efficiency of public transportation. The innovative business mode of

mobike ushered in the "no-pile" era of public bicycle rental. Mobike has solved the pain points of travel through technology and market forces, and promoted the green cycling culture. At the same time, it is a new practice of the sharing economy in society. The concept of sharing bicycles needs to be carried out with the integrity and public morality of users, while mobike also needs to combine public welfare and business to achieve its sustainable operation.

Research on the Value Proposition Innovation of Two-sided Market Enterprises

Yan Linfei, Diao Zhaofeng
School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: 1427276364@qq.com, diaozf@163.com)

Abstract: The importance of two-sided market enterprises continues to be highlighted in the current economic environment.Based on the bilateral market theory and the two-sided market model, this paper compared and analyzed the value propositions of value chain enterprises and two-sided market enterprises.After summing up the value elements of the two-sided market enterprises, this paper drew the value curve of two-sided market enterprises by drawing on the four actions framework in the *Blue Ocean Strategy*, and then compared with the original value curve. Finally, it provided ideas and methods for value proposition innovation of two-sided market enterprises, enriched the business model innovation theory.

Key words: Two-sided market; Value proposition; Four actions framework;Value curve

1 Introduction

The rise of the Internet economy and the development of information technology have spawned a frontier theory- the theory of bilateral markets.The bilateral market involves two distinct types of users. Each type of user gains value by interacting with another through a common platform (Wright, 2004).Rochet and Tirole first defined the bilateral market from the perspective of platform pricing in 2004, and then Armstrong redefined the bilateral market from the perspective of network externalities in 2006.As an enterprise form of bilateral market in the era of network economy, two-sided market enterprise plays a very important role in economy.Enterprises are not only concerned with providing value to customers, but also paying attention to providing value to merchants. At this time, enterprises are facing two customer groups (Tse, 2012). These platforms which are operating in two-sided market clearly differ significantly from those in the unilateral market and therefore require different business models. In recent years, business model innovation is a topic of concern for enterprise value innovation, while value proposition is the foundation and source of business model innovation, and it runs through the innovation of business model. Therefore, it is very necessary to research the value proposition innovation of two-sided market enterprises.

Business model innovation focuses on defining value propositions for customers, merchants, and partners (Casadesus-Masanell and Zhu, 2013). In value proposition design, unlike the traditional business model, the value proposition design of the Internet business model pays more attention to driving the customer's pain points (Osterwalder, 2015).However, at present, there are few achievements in the study of value proposition innovation of two-sided market enterprises, and it does not clearly indicate how two-sided market enterprises should conduct value proposition innovation.Therefore, this paper based on the bilateral market theory and two-sided market model, drew lessons from the four actions framework and the value curve of the *Blue Ocean Strategy* (Kim and Mauborgne, 2005) to conduct an innovative research on the value proposition of the two-sided market enterprises.

2 The Value Propositions of Two Types Enterprises

2.1 The value proposition of value chain enterprises

In the value chain model, the core of enterprise concern is how to expand its product market.Therefore, the enterprise adopting value chain business model mainly implement the strategy of product centralization.Value chain enterprises pay more attention to customer's value proposition with the view of traditional vertical value chain, to create more value for customers and satisfy customer's value demands, but may be less concerned about the value proposition of upstream suppliers.

2.2 The value proposition of two-sided market enterprises

Conceptually, the two-sided market is very similar to the bilateral market.The basic structure and research foundation of two-sided market model are basically consistent with that of bilateral market theory. From the perspective of the economic model, they are essentially indistinguishable.The core of the two-sided market business model concerns the desires and abilities of the customers in two sides, and combines the resources and capabilities of one side to another, in order to satisfy the desire of the

other side. Therefore, the two-sided market model far exceeds the value chain model in understanding of customers.In the two-sided market model, customers mean not only the objects of the enterprise selling products or services,but all members of the supporting enterprise ecosystem.Two-sided market enterprises not only focus on providing value to customers, but also providing value to merchants and other stakeholders in the ecosystem (Chen Weiru, 2013).The two-sided market realizes mutual interaction through platform companies and achieves two-way positive feedback. As a result, the amount of resources and customers on two sides rises.Enterprises adopting two-sided market business model implement customer-centric strategy, as shown in Figure 1.This paper focuses on the research of business model innovation, which belongs to management science. Therefore,it uses the two-sided market model proposed by Professor Tse instead of the bilateral market.

Figure 1   Two-sided Market Model

3 The Value Proposition Elements of Two-sided Market Enterprises
3.1 Customer value proposition elements

The customer value proposition of two-sided market enterprises has different elements from the traditional value chain enterprises.Great value propositions focus on the pain points and benefits of customers and help them eliminate pain points (i.e. unwanted results, problems and features, obstacles, risks) (Osterwalder, 2015).The value proposition of two-sided market enterprises needs to reduce the pain points of customers, and put forward a plan to relief their pain points, or create customer benefits.Customers expect low price and high quality products with a wide range of products to choose from.Customization is also a very important value factor, especially in two-sided market enterprises, which is unique (Fran ça et al., 2016), and is achieved by the network effects in two-sided market.In addition, the convenience of payment and purchase, the availability of distribution logistics, and the safety of customers' information are all included in customer value proposition elements.

3.2 Merchant value proposition elements

According to the stakeholder theory, the survival and development of enterprises does not only depend on capital investment, but also on the input of stakeholders such as corporate managers, consumers and suppliers.Therefore, apart from focusing on traditional customer value propositions, two-sided market enterprises also need to consider the value proposition of merchants.And because of the existence of network effects in two-sided market enterprises, it is particularly important to consider the value proposition of merchants.Merchants expect higher revenues and reduce spending, also expect an efficient flow of information to capture user behavior and consumption trajectories so that they can accurately capture and use inventory levels, orders, production, and delivery of information in the supply chain, which can reduce uncertainty in the supply chain.At the same time, merchants expect that the platform will provide them with professional technical guidance and support, such as CRM, and lower the entry threshold.

3.3 Network effects

Network effects are the biggest difference between platform business model and traditional business model.The value of a platform to one user group often depends on the number of users of the other party, while a platform is valuable only if the relevant user group exists at the same time (Zhang Xiaoning, 2015).The network effects in two-sided market enterprises are divided into two parts:same-side network effects and cross-side network effects.Same-side network effects are more obvious on the customer side. When more customers purchase, more customers will be attracted. The utility of the customer will increase with the number of customers using the product.Cross-side network effects are the precondition for the establishment and operation of platform model. Moreover, cross-side network effects can reduce the marginal cost of two sides, which are represented as the decrease of cost in the merchant side and the decrease of price in the customer side.

Due to the network effects, the merchant's value proposition and the customer's value proposition should meet.Some business models only work when multiple value propositions are combined with a customer base.In two-sided market enterprises, higher value creation provided by the merchant side will attract more customers, and more customers, in turn, will attract more suppliers, thereby further creating

value and enhancing the value proposition on two sides. Therefore, the value elements brought by the network effects include the market information and professional technical support required by the merchant; the customer's expected price comparison function, distribution logistics, customization, and information security.

In summary, the value elements of the customer, merchant, and network effects of two-sided market enterprises can be summarized as Table 1.And they can be divided into positive and negative value elements.The positive value elements can be expressed in the figure as the higher the value element point, the higher the value (for example, the more convenient of the customer to pay, the higher the value for it); The negative value elements show that the lower the value element point, the higher the value (for example, the lower the price paid by the customer, the higher the value for it).

Table 1   Summary of Value Elements

Value elements	Customer side	Merchant side	Network effects
Positive	Payment convenience		Technical Support
	Product type		Market information
	Service		Customization
	Purchase convenience		Price comparison
			Distribution logistics
Negative	Price	Barriers to entry	Information security
		Inventory	
		Store	
		Cost	

4 The Ideas and Methods of Value Creation in Two-sided Market Enterprises

4.1 The ideas of value creation in two-sided market enterprises

There are three principles of value innovation in the *Blue Ocean Strategy*: focus, divergence and compelling tagline, which also apply to two-sided market enterprises.In addition, there is a unique principle of two-sided market enterprises that is the prominent network effects.Network effects can bring value elements for two-sided market enterprises that traditional value chain enterprises lack, such as providing market information for merchants, giving them professional technical support (such as CRM, etc.), providing customers with parity functions, distribution logistics services and satisfying customization demand.And in the innovative two-sided market enterprises, the value of the value elements brought by the network effects are obviously higher than the general two-sided market enterprises.

Based on customer and merchant claims, this paper combines the four actions framework to change the both customer and merchant's value proposition elements to determine the value proposition elements of the two-sided market enterprises, as shown in Table 2. These value elements are plotted in the figure and connected to form the value curve.

Table 2   ERRC Grid of Two-sided Market Enterprises

	Merchant side	Customer side
Eliminate	Store; Barriers to entry	
Reduce	Inventory; Cost	Price; Information security
Raise	Market information	Service; Product type; Payment convenience; Purchase convenience
Create	Technical support	Distribution logistics; Customization; Price comparison function

4.2 The methods of value creation in two-sided market enterprises

This paper uses the four actions framework based on the drawing of the value curve proposed in the *Blue Ocean Strategy*, and cites and innovates it to design a value curve which is suitable for two-sided market enterprises.Extending the original coordinates will highlight the bilateral relations in two-sided market enterprises.

In this paper, Taobao, supermarket and vendor are selected for comparison, only for example (as

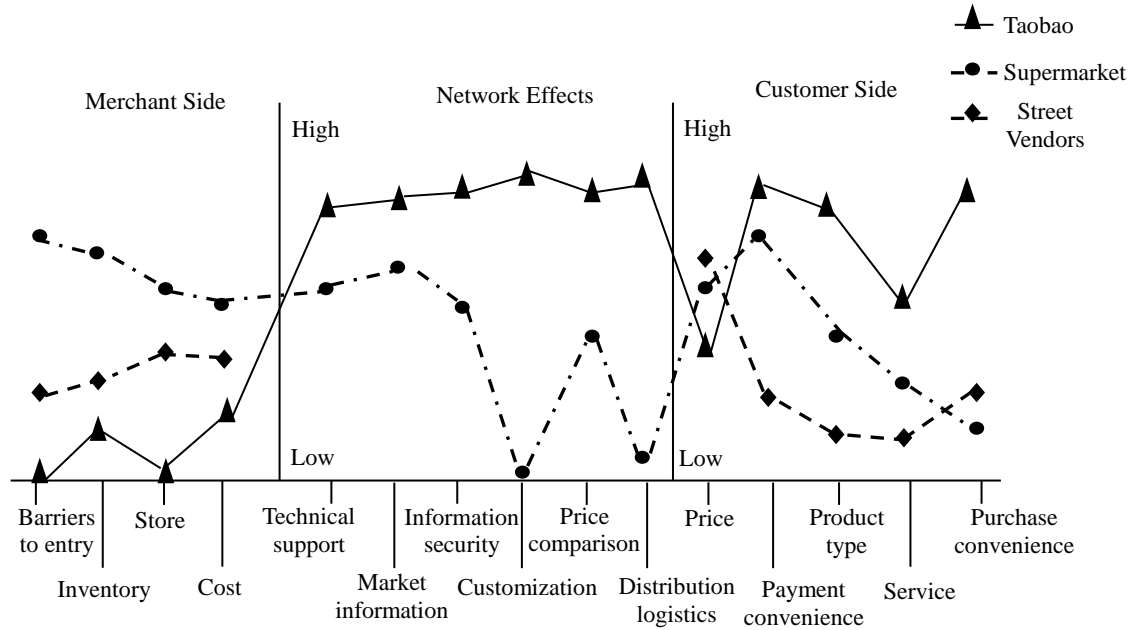
shown in Figure 2).The first two are two-sided market enterprises, the latter can be seen as traditional enterprise.The value elements of the three are analyzed and plotted on the figure. Finally, the element points are connected to form a value curve.


Figure 2   Two-sided Market Enterprises Value Curve

From the Figure 2, it can be clearly seen that two-sided market enterprises have distinct advantages over traditional enterprises: the value elements such as market information and technical support in merchant side, and the value elements of distribution logistics, price comparison, and customization in customer side have significant advantages.These value elements are brought about by the unique network effects of two-sided market enterprises. But at the same time, there are problems with information security. Therefore, two-sided market enterprises should focus on how to ensure customer's information security.

In addition, innovative two-sided market enterprise (such as Taobao) has its advantages in the value curve compared with the general two-sided market enterprise (such as supermarket).Two-sided market enterprises can determine the value elements of merchants and customers based on their own situation, and sort them according to the actual situation, and finally connect the value elements to form a value curve.And compare it with other related enterprises to find value propositions that meet the three principles of focus, divergence and compelling tagline, and have network effects is more importantly.

5 Conclusion

On the basis of reviewing a number of literatures, this paper compared the value propositions of two-sided market enterprises with value chain enterprises,summarized and analyzed the value elements and used four actions framework to innovate and design, finally it was concluded the two-sided market enterprises value curve.The innovative value curve has the following advantages:First of all, in the shape, the new value curve breaks the shackles of the existing industry value curve, trying to distinguish and highlight the proportion of various factors. Secondly, it extends the original value curve, extending from the original focus on the customer to the attention of both the customer and the merchant, and is more applicable for the two-sided market enterprises. The new value curve creates value innovations for customer's pain points, and at the same time pays attention to merchant's propositions and values.

However, due to my lack of practical experience, the practice of the value proposition innovation methods proposed by the two-sided market enterprises remains to be proved.Therefore, practical verification is needed in future research. Moreover, the extraction and measurement of value proposition elements of two-sided market enterprises can be researched in further study. In addition, the ideas and methods of value proposition innovation research may also be used for reference by other industries or enterprises to transform.

Abstract: In current years, the development and construction of regional theme parks has been booming in China with the overall development of tourism industry. Since the competition among regional tourism markets has become increasingly fierce, how to enhance the core competence of regional tourist attractions' theme has become one of critical issues of researching tourism strategic development and macro decisions. This article applies literature retrieval of the concept of core competence, and also utilizes statistical analysis and empirical analysis to conclude current status and problems of tourist attractions involved in Hubei Province of China, and then to proposes effective strategies for improving the core competence of theme parks in Hubei, and finally overall which will be the beneficial revelations to other provinces or cities in China.
Key words: The core competence; The theme park; Strategies; Hubei province

1 Introduction

With China's rapid economic development and continuous improvement of living standards, the last 40 years have witnessed great development of tourism industry according to the policy of economic reform and Open Door. China has become a veritable tourist destination. And also, more and more attention has been paid for tourism's industrial status and function. Especially for recent years, tourism economy has become an important part of national development strategies. The main function of developing tourism industry is not only to gain exchange revenue or financial reward, but also to serve social life, to enhance the vitality of market economy, to meet the growing consumers' demand, to promote international exchange and cooperation, to improve the image of the state which have shown that development of tourism in China has entered into a new historical stage.

While, the year of 2016 is the key year to implement the "Twelfth Five-Year Plan" and the year of 2017 is the important year to conclude "Twelfth Five-Year Plan" and prepare "Thirteenth Five-Year Plan" in China. Furthermore, the year of 2018 is a key milestone of the policy of "Open Door" and "Supply Side Reform". Many researchers have taken more attention and hot debates to the next new round of reform of tourism industry in Chin, such as tourism industry in China should focus on solving problems of changing the way of tourism economy growth, improving operational performance, reforming tourism products supplying, optimizing structure of internet+ supply and demand, improving satisfaction have been involved in current research.

Moreover, this paper pointed out that aspect of improving the core competence of the theme parks in central cities of China have become a very important part to promote the supply side reform of tourism industry in China since the developing and constructing regional tourist attractions has been booming in recent years. For the central regional districts in China, more and more market suppliers have been planning special theme parks to attract tourists. Since the number of regional tourist theme parks has ever increased, the competition among regional tourism markets has become increasingly fierce. Therefore, how to enhance the core competence of regional tourist theme parks and avoid duplicate construction has become one of the critical issues of researching tourism strategic development and macro decision.

2 Current Developing Status and Problems of Theme Park in Hubei Province

2.1 Current developing status

During the last ten years, the tourism industry in Hubei Province has experienced rapid development with the great support and emphasis from government. Total tourism revenue, numbers of inbound and outbound tourists, and tourism attractions' construction have gain rapid growth in Hubei. In 2017 tourism comprehensive strength of Hubei ranked as the 13th in China. Hubei province owns unique tourism resources, such as beautiful natural sceneries, rich cultural landscapes and magnificent modern architectures. Hubei has formed a group of well-known cultural tourist attractions as the theme

of the "Three Gorges" and "Three Kingdoms" through years of development. According to the statistics of Hubei Provincial Tourism Bureau, till the year of 2017, Hubei had total 368 A-level tourist attractions. Respectively, there were 10 AAAAA tourist attractions, 124 AAAA tourist attractions, 177 AAA tourist attractions, 55 AA tourist attractions and 2 A tourist attractions. While, there were also 85 theme parks involved in. Furthermore, 12 National Excellent Tourism City were listed in Hubei (Hubei Tourism Bureau, 2011-2017).
Figure 1   Hubei A-level Tourist Attractions Volume 2012-2016

However, Hubei is not a strong province among competition of national tourist theme parks while it has long been a major tourism resources' province. There is a huge gap between Hubei and other developed regions in tourism industry and tourist attractions. For the quantitative area of tourist attractions' developing and constructing, as Figure 1 show following, A-level tourist attractions and industrial and agricultural demonstration sites in Hubei increased steadily in recent 5 years. But, the average growth rate was rather less, and also Hubei had been lagged behind other developed regional tourist attractions.

While, for the qualitative area of tourist attractions' developing and constructing, as Table 1 shows, Hubei lacks of beyond AAAAA tourist attractions and national-level industrial and agricultural demonstration sites, and they developed particular slowly in recent years. Huibe only owned 10 AAAAA tourist attractions, and beyond AAAA tourist attractions in Hubei just accounted for 2.7% of national total in 2016 (National Tourism Administration of the People's Republic of China, 2008-2010), which shows that the core competence of Hubei tourist attractions has been so poor and the conflict between the quantity and the quality of tourist attractions in Hubei has been serious.

Furthermore, there was none accurate statistics for the theme park involved in tourist attractions developing database. It is only to get probable data according to certain booking website of tourist attractions. There were about 85 theme parks until 2017 in Hubei Province and none of one has been involved in AAAAA tourist attractions.

Table 1   Classified Statistics of Different A Levels Tourist Attractions in Hubei

Level Year	5A	4A	3A	2A	1A	General industrial and agricultural tourism demonstration sites	National industrial and agricultural tourism demonstration sites
2012	7	95	110	50	3	67	23
2013	8	100	133	48	3	73	23
2014	9	115	139	66	3	73	23
2015	10	117	156	61	3	/	/
2016	10	124	177	55	2	/	/

Moreover, for the area of scenic tours' income, as shown in Table 2, Hubei gained steady growth year by year. Although in the year of 2012, the income of Hubei scenic tours increased particularly, the development and construction of tourist attractions hadn't contributed too much for the total tourism

income in Hubei. For the composition of domestic tourism income and inbound tourism foreign income, compared with long-distance transport, ticket sales, accommodation, catering, entertainment, shopping and other income factors, domestic scenic tours and inbound scenic tours respectively average share less of the total, which showed that the economic benefits of tourist attractions in Hubei should be further improved.

Table 2   Total Tourism Income of Hubei 2012-2016

Year	Total income (100 million Yuan)	±%
2012	2629.54	31.95
2013	3205.61	21.9
2014	3752.11	17.05
2015	4308.76	14.84
2016	4888.51	13.45

2.2 Current developing problems

2.2.1 Overall market structure has been in "small, weak, poor and disordered" status

Although tourism resources, regional features and historical culture in Hubei are rich and various, the conflict of "small, weak, and disordered" is obvious. In addition to some individual theme parks in Hubei have reached certain scale strengths, most of others have been in the status of "small" (small scale, less large corporation groups, less cross-joint), "weak" (weak capital, weak comprehensive strength, weak competitiveness), "poor" (decentralized operation, fuzzy target, poor infrastructure construction), "disordered" (poor management, poor site selection, poor service, poor economic efficiency).

2.2.2 The characteristics, cultural level and popularity of theme parks have not been so high

For the natural resources, although some theme parks in Hubei have obvious advantages like beautiful natural environment, peculiar geological features and rich historical and cultural connotations, many excellent background resources and scenic products could not become the true goods that tourists can accept and love resulted from the unclear tourism theme, less attraction, less geographical and cultural characteristics and without clear travel purposes. Furthermore, for aspect of the artificial construction, certain theme parks such as the famous "Wanda Film Park" which located in the central city of Hubei only operated for one year finally according to the problems of recognition, popularity and management.   Therefore, the recognition, cultural level and popularity of theme me park in Hubei have always been so poor nationwide.

2.2.3 Poor public facilities and service provided

A number of top grade service facilities are basic conditions for developing tourism industry, especially for the operation of theme parks. Although the quantity of development and construction of theme parks have gained too much progress in Hubei, the improvements of public tourism facilities are so poor, such as high star-level hotels involved in theme park, restaurants, tourist rest centers, public parking areas, souvenir shops, wastes disposal stations and emergency medical treatment sites are needed to be developed in most of Hubei theme parks in the following years. Problems of peak travel congestion, non- standardized supporting and management, dirty & chaotic & poor tourist spots directly lead to greatly reduce the enthusiasm of tourists; and also, negatively influence the quality of service and business satisfaction of Hubei theme parks. Furthermore, developing important hardware environment and monitoring service quality during reception facilities' construction have been backward in Hubei. Moreover, the internal quality of employees and managers of the theme parks needed to be further improved, especially for introducing and training numbers of professional and technical personnel, excellent management personnel.

2.2.4 Insufficient marketing

As market competition intensifies, a variety of marketing activities have become an important approach for theme parks' competing. But, most of the theme parks in Hubei haven't made clear awareness of the nature of themselves and also the value for marketing. Because of less input and oversimplified marketing methods, topic concepts and theme image of Hubei theme parks have always not been clear and obvious, which result in Hubei usually lacks of creative marketing tipping points and idea to attract tourists. And many theme parks had the same themes. Meanwhile, the marketing channels of Hubei theme parks are relatively dispersed. Therefore, distinct theme, seasonal, powerful, high-impact marketing needed to be delivered.

2.2.5 Poor internet+ technology applied

Widespread application of internet+ technology will play an important role to develop modern tourism industry. Many theme parks only apply internet+ technology on the area of tickets booking. But, for the aspect of applying the depth and effect of internet+ technology, there is very few theme parks in Hubei applies such information technology and therefore the popularity has been so low. The networking system among tourist attractions and travel agents, hotel, transportation system and other related departments related to theme parks' daily operation has been underdeveloped. Also, sufficient contact with tremendous impacting computer systems, the networking of Hubei theme parks is only just in beginning. There are reasons for their own area and also for industrial relations and macro systems which lead to above problems. For instance, online price is always not transparent; it's hard to balance expected return and actual revenue; which seriously affect the enhancement of the core competence of Hubei theme parks and the sustainable development of the whole tourism industry in Hubei Province (Chen Hui, 2013).

2.2.6 Inadequate enthusiasm to innovate products of theme parks

Since the low level of market concentration and conflict of "small, weak, poor and disordered" is obvious, many theme parks in Hubei always tend to focus on the immediate advantages and benefits, but not to concern with the long-range development and continued innovation of new products related to theme parks. While the medium and small theme parks always have no ability and strength to carry out product exploring and innovating, they preferred to operate traditional products and to achieve benefits by conduct low-price strategy when competing with large theme parks. In addition, there have no any powerful systems and laws to protect intangible assets such as innovation of theme parks' deuterorgenic products. Therefore, most of theme parks have not adequate enthusiasm to innovate products of tourists' attractions since researching, developing and protecting new tourism products are so difficult.

2.2.7 Lack of top-grade brand

Hubei is not a strong province among national tourism industry while it has long been a major tourism province, lacking of top-grade tourist attractions is one of reasons. For the theme parks, it also involved in this problem. When summarizing successful experiences of tourism developed provinces, it usually could list some top-grade tourist attractions and theme parks with world-renowned reputation and high social recognition. To develop tourism destination based on the top-grade tourist attractions, and thus form a complete industrial chain of regional tourism industry to support sustainable development of regional tourism economy. Most operators of Hubei theme parks often pay more attention to economic benefits, but neglect to enhance the quality and grade of tourist attractions, which result in Hubei not only lacks of top-grade theme parks, but also a huge gap existed between Hubei and other tourism industry developed regions.

2.2.8 Inappropriate locating of theme parks

The theme park is a tourism investing project with large investment and high risk. Scientific and reasonable location is the key to the success of theme parks' investment. And the factors influencing the theme parks' location are related to the market, the investment environment, the natural conditions, convenient transportation and cultural factors. Since the theme parks have been popular in recent years in China, companies flocked in to build theme parks in Hubei without appropriated consideration and research on location of theme parks, which resulted in the repeated theme of tourism parks concentrated on a certain district or long-distance theme parks located in a rather remote place.

3 Definition of the Core Competence of the Theme Park
3.1 Definition of the core competence

The earliest study on the core competence of the corporation could be traced back 60 years before. Kenneth Andrews thought that corporate strategies defined business areas that corporate would participate in, and also would focus the company's resources to transfer variety abilities into competitive advantage (Li Yijing, 2004). In 1990, two American strategic management experts named Prahalad, C.K. and Hamel G firstly pointed out the concept of the core competence of the corporation by publishing the paper titled as "The Competence of The Corporation" on Harvard Business Review (HBR). Core competencies are the collective learning in the organization, especially how to coordinate diverse production skills and integrate multiple streams of technologies. The core competence is the source and foundation of gaining sustainable competitive advantages, which mainly determined by its characteristics.

Firstly, a core competence should make a significant contribution to the perceived customer

benefits of the end product. Second, a core competence should be difficult for competitors to be imitated, replaced and surpassed; and it will be constructed difficultly if it is a complex harmonization of individual technologies and production skills. Third, a core competence could be extendable; it provides potential access to a wide variety of markets. Fourthly, a core competence is interrelated. It is a collection of skills and technologies, rather than scattering individual skills or technologies. Fifthly, a core competence is obtained by accumulated studying. Lastly, a core competence is dynamic, which means that it is not fixed, and it needs to be timely protected and innovated by the changing external environment (Prahalad, C.K., Hamel G, 1990).

3.2 The core competence of theme parks

According to "Report of Development and Operation Pattern & Investment Opportunity on China Tourist Attraction (2018-2023), till the year of 2015, there have been over 7000 A-level tourist attractions, key national scenic areas such as 4A and 5A tourist attractions have been over 1500 (National Tourism Administration of the People's Republic of China, 2018-2023). Tourist attractions have been formed the half of China's tourism industry. At present, tour of tourist attractions has been the major advantaged constructing projects of tourism industry in China. And it will also focus on developing new tourism products such as leisure tour, exhibition, family & children's tour and ecological tour to enrich the domestic tourism market. Therefore, the competition among regional tourist attractions will become increasingly fierce.

According to the definition of the core competence of corporate and characteristics of tourist attractions, the core competence of theme parks could be defined as the unique competitiveness that formed by long-term development and finally blended into the endoplasm of tourist destination to support their competitive advantages which could help theme parks to gain sustainable development during fierce competition. The core competence of theme parks must be able to achieve the core value that tourists valued. And for the way of competition, it should be difficult to be imitated, replaced and surpassed compared with other competitors. For the perspective of theme parks' further development, it should be extendable, which means the extended process of "the core competencies- the core technologies- the core products - the final products" exits. Furthermore, it should be interrelated and could be obtained by accumulated studying. Moreover, these kinds of core competencies will be timely protected and innovated by the changing external environment rather than to be fixed. In addition, the core competencies of theme parks are the sustainable development abilities that tourist destinations could obtain by integrating various business managing operating methods, such as strategic planning, decision making, brand building, applying modern information technology, effectively allocating human resources and establishing a corporate culture (Zhang Yuqiang, 2010).

4 Strategies of Improving the Core Competence of the Theme Parks in Hubei

As the current status and problems discussed above, it could be conducted by following five strategic approaches to enhance the core competence of theme parks in Hubei.

4.1 Re-integrating tourist destinations' resources and facilities within the framework of Hubei Province

Although Hubei has rich tourism resources and great potential for developing theme parks, constraining factors such as unbalanced developing steps in the south, central and north, and traffic connecting & parking problems have limited the quick development of Hubei theme parks for a long time. Also, enterprises operating theme parks with small, weak, poor and disordered made theme parks cannot achieve benign connectivity and extensibility within the framework of total Hubei Province, which resulted in the phenomenon of fragmented nature of local government and local tourist destinations. Therefore, Hubei needs to effectively integrate current tourist destinations' resources and facilities within its scope, to rationally distribute the space of provincial tourist destinations, to form large-scale regional tourist destinations, to perfect physical environment and conditions of tourist destinations' sustainable development, and to play effect of capital accumulating by re-organizing large-scale tourism groups operating theme parks, and to construct some theme parks with top-grade brand which are symbols of Hubei; then it could enhance an overall competitiveness of Hubei theme parks.

4.2 Enhancing the core value of traditional theme parks while constructing high recognized theme parks

Tourism resources are the core of tourist destinations to attract tourists. It should focus on exploring the unique and unmatched characteristics of tourism resources when developing tourist attractions.

Therefore, Hubei should enhance and extend the core value of rational tourist attractions (such as Three Gorges and Shenlong jia) while develop a number of theme parks with unique characteristics to attract tourists (such as leisure tourism and ecological tourism).   And then to form certain scale of top-grade theme parks to achieve coordinated development of Hubei tourist attractions within areas of the quality and the quantity. Furthermore, the aspects of tourists demand-driven from time to time, providing professional tourism services, timely introducing innovative theme parks' related products and reasonable pricing are also important to enhance the core competence of Hubei theme parks (Zeng jianmin, Wu Zongjian, 2011).

4.3 Building and marketing top-grade brands of theme parks in Hubei

Brands reflect the core competencies of theme parks during information age. Brands are powerful approaches strengthening differentiation of tourism products, and also the key link to achieve competitive advantages.   Creative, clear, attractive and stable tourism image and theme will promote rapid development of theme parks. However, the problems of indistinct theme image and poor marketing of theme parks have resulted in poor comprehensive competitiveness and weak fame of Hubei theme parks, which restricts long-term development of Hubei theme parks. Therefore, it needs to further build advantaged top-grade theme parks that could represent Hubei based on strengthening re-integrating resources of tourist destinations and forming unique top-grade brand of Hubei theme parks (Hou Liyuan, 2013). Furthermore, it also needs to conduct tourism marketing around top-grade theme parks and to apply network marketing strategies to improve multiple effect of marketing theme parks' products, to attract social attention and capital investment, and then to explore high added-value tourism products around the brands to improve the competitive advantages of core tourist destinations (Ding Xiaonan, 2013).

4.4 Revolting management systems of operating the theme parks

Managing theme parks is an extremely complex and important process. Good tourist destinations' resources must be supported by a comprehensive management system be operated by excellent managers and good employees. It should be improved by creative management philosophy, which then could further enhance the core competence of theme parks. Therefore, Theme parks in Hubei should revolting current management systems, especially for introducing and employing excellent employees, applying scientific management modes, building corporate culture and innovating investment and financing channels (RT Rust, VA Zeithaml, AKN Lemon, 2013).

4.5 Establishing dynamic alliance of the theme parks

With consuming concepts of tourists have tended to be diversified and personalized, the uncertainty of market demand increases greatly which requires corporations of tourist attractions should have the flexibility and strong market adaptability. Model of competition & cooperation is the right choice for operating theme parks. One theme park usually has one or more business advantages, but it could form a more advantaged value chain if number of theme parks integrating their different advantages and then forming complementary alliance to re-construct value chains of individual, which then will create unique competitive advantages for alliance theme parks (Chen Hui, 2013). Therefore, Hubei should break the traditional concept of competition, to establish awareness of "win-win" cooperative competition, to use of modern network technology and to breakthrough limited boundaries between tourist attractions to combine all the competitive advantages itself and other tourist attractions in addition to pure competition, and finally to form a limited alliance organizations which could extend and integrate individual function and advantages to enhance core competencies of both individual and overall Hubei theme parks (S Çifci ,Y Ekinci, 2016).

5 Conclusion

With the revolution and reform of Supply-side in China, great challenges and opportunities have taken place in tourism industry. Although tourists have great enthusiasm to enjoy their leisure time, satisfied tourism destinations have been rather less. The theme Park is one of the key parts of regional tourist destinations. Since the competition among regional tourism markets has become increasingly fierce, how to enhance the core competence of regional tourist attractions' theme has become one of critical issues of researching tourism strategic development and macro decisions. This paper takes Hubei province as the case to study the concept of core competence of tourist attractions, and also proposes strategies for improving the core competence of theme parks in Hubei through analyzing its current status and problems involved in.

Research on Business Mode Innovation of Mobile Internet: A Case of Mobike Bicycle-sharing

Li Lin
School of Economics and Management, Wuchang Shouyi University, Wuhan, P.R.China, 430064
(E-mail: marketinglee@126.com)

Abstract: Business mode has a significant role in promoting corporate performance, enhancing market position and strengthening competitive advantages. The business mode innovation has gradually become an important source of enterprises to improve performance and gain competitive advantages, so more and more enterprises conduct business mode innovation in the era of mobile internet. This paper adopts a case study of "Mobike bicycle-sharing" based on the perspective of mobile internet, the paper includes four major parts. Firstly, the paper reviews and comments on the main types of modes based on the domestic and foreign literatures from 1996 to 2018. Secondly, it elaborates the characteristics of mobile internet business mode and describes the factors which influence business mode innovation. Thirdly, it introduces the mobile internet business mode innovation practice of Mobike and summarize the work experience. At last, it proposes to the countermeasures about the business mode innovation for Mobike.
Key words: Mobile internet; Business mode; Business mode innovation; Mobike

1 Introduction

The concept of business mode was proposed as early as the 1950s, but its rise was due to the rapid development of the internet economy (Yang Xia, Wang Liangliang,2015). Peter F. Drucke said, "The competition among enterprises today is not the competition between products and services, but the competition between business modes. The business mode is not just how businesses make money, how to get income and profits." (Yunus M., Moingeon B., Lehmann-Ortega L.,2010). In the era of mobile internet, the design, reengineering and innovation of business models are science and art that must be mastered by the enterprises. It effectively solves the fundamental problems of the survival, development and growth of the enterprise via the business mode innovation. In recent years, the domestic and foreign scholars generate a lot of valuable research achievements. Foreign scholars not only define the definition, types and characteristics of business mode, but also put forward the implement ways of business mode innovation strategies. In this part the paper introduces basic concepts of business mode and business mode innovation based on the inductions and reviews of current researches.

1.1 Research on the definition of business mode

Some scholars count a number of published academic and non-academic articles from 1975 to 2009, people's concern for business modes started at 1995 (Zott C., Amit R., Massa L., 2011). There is no uniform definition of business mode, most of the scholars abstract the definitions based on the specific perspective, these definitions can be divided into five types which reflect the different emphasis.

1)Business mode is the specific ways and means of how an enterprise engages in business. (Amit R., Zott C., 2001)

2)Business mode is various trading relationships and links among stakeholders, it emphasizes the trading mechanism. (Amit R., Zott C., 2001)

3)Business mode is a summary that an enterprise obtains and maintains revenue. (Stewartal, 2000)

4)Business mode is a series of ideas for how an enterprise can serve its customers and all participants who maintain the normal operation of enterprise by creating value. (Magretta J., Stone N., 2002)

5)Business mode is a multi-factor system, it is a framework for products, services and information flow. (Paul T., 1998)

1.2 Research on the constituent factors of business mode

Nowadays, system-based views have become the mainstream of business mode concept research. The following three modes are widely recognized among the many views. (Cheng Wen, Wang Yingjun, 2014).

1)This mode includes nine factors of core competencies, resource allocation, value propositions, distribution channels, target customers, partnerships, customer relationships, cost structures and profitability pattern. (Osterwalder A., 2004)

2)This mode includes four factors of core strategy, strategic resources, customer interface and value

network, every factor included subfactors. (Hamel G., 2000)

3)Business mode is considered as a business activity system that describes how companies "do business" with customers, partners, and suppliers. (Amit R., Zott C., 2012)

1.3 Research on the mobile internet business mode innovation

Business mode innovation refers to the activities of designing a new business mode, such as creation, implementation, and verification activities. Business mode innovation is not only the innovation of products and processes, but also the innovation of the business mode structure, the process of creating value and gaining value for stakeholders through the search for new business logic and methods (Amit R.,Zott C., 2012).Business mode innovation is refers to innovation in value creation, value proposition, and value acquisition(Clauss T., 2017).Some scholars propose business mode innovation includes industrial mode innovation ,revenue mode innovation and enterprise mode innovation. Some scholars propose business mode innovation includes progressive innovation and breakthrough innovation. Some scholars propose the path based on constituent factors, the path based on process and the path based on value chain. Organizational inertia, thinking mode and identity trap are the barriers to business mode innovation (Tian Qing Feng, Zhang Yinyin, 2018). There is no uniform definition of business mode, scholars define the business mode based on path, operations, profit, strategic positioning and system theory. Some scholars divide the constituent factors of business mode. The current researches play a fundamental role enriching the business mode theories through the analysis of above literatures, but the researches on practice of business mode innovation are rare. Thus, this paper puts forward suggestions for business mode innovation of Mobike with literature research and case analysis.

2 The Characteristics of Mobile Internet Business Model

There are big differences between internet business mode and traditional business mode. For one thing, internet business mode brings innovation to the communication channels of enterprise. For another thing, internet business mode caters to the consumption patterns of consumers.

With the emergence of internet technologies such as big data, traditional enterprises are facing big challenges, so it is particularly important for enterprises to adapt themselves to the current development trend in the new environment. For one thing, the network and mobile communication technologies are changing the life style of human beings in all directions, the consumption demand shows changes in individualization, autonomy and complexity, so it objectively requires enterprises to adapt to the new situation of diversified and personalized consumption. For another thing, the development of e-commerce and social platforms provide multiple ways for businesses to innovate in business modes, many enterprises can obtain competitive advantages via innovative business mode. Mobile internet represents a new economic form that bringing about changes in the production and consumption patterns of traditional industries. The mobile internet business mode refers to a new business operation and organizational structure mode with high innovation, high value, high profitability and high risk. The characteristics of the mobile internet business mode are reflected in the following aspects:

1)Mobile internet business mode is based on the internet. Platform economy is the main theme of mobile internet, the winners of both the internet rookie and traditional enterprise transformation are platform-based, such as Alibaba, Tencent, Xiaomi, Jingdong, the internet becomes the primary source of information. Mobile internet business mode uses the internet as a medium and integrates traditional business types and connects various commercial channels.

2)Nowadays, data has become an important production factor with physical assets, technology, and human capital. Big data refers to massive, high growth rates and diversified information assets with stronger decision-making power, insight and process optimization capabilities. Mobile internet business mode regards big data (volume, velocity, variety, value, veracity) as the core production factor, so big data processing and analysis capabilities become the enterprises 'score capabilities.

3)The focus of business is shifting from material to human, the driving force is changing from flow to relationship, the measure of business is changing from value to value concept. With the penetration of mobile internet in various industries, the cross-over competition barriers of enterprises have been greatly reduced. The cross-over and cross-over integration are self-revolution for the enterprise.

4)For one thing, the development and application of mobile internet technology can create a highly detailed market, accurately identify the individual needs of users, adjust products and services to meet these needs. For another thing, the development and application of mobile internet technology, the consumption patterns that are generated by one-way flow of information quietly changed. Consumer can

participate in the value creation process of the company through various ways, the consumer no longer a passive end-consumer but a proactive searcher.

3 Case Selection and Case Analysis
3.1 Case selection and introduction

Bicycles-Sharing is a new type of bicycle rental business, it refers to the sharing of bicycles on campus, subway stations, bus stops, residential areas, commercial areas, public service areas, etc. Bike-sharing has grown into a massive phenomenon in China over the past two years, and over 30enterprises offer colorful bicycles. Mobike starts its business in Shanghai in 2016 and spread to over 180 major Chinese cities, as well as Singapore, United Kingdom, Italy, Japan, Thailand, Malaysia, United States and South Korea, with 7 million bicycles worldwide. Mobike becomes the world's largest intelligent shared bicycle operating platform and mobile internet platform. Mobike creates the world's first smart shared bike mode, the users can locate a bike use an app and it only costs 2RMB per hour, the users can leave the bike anywhere they want without having to return it to a specific location.

This paper chose the typical case of Chinese Bike-sharing industry to conduct research. The enterprise is selected to meet the following three conditions: Firstly, the enterprise must have a good brand reputation, high market share in Chinese Bike-sharing industry. Secondly, the enterprise's business mode innovation is effective. Thirdly, there are some problems in enterprises business mode innovation and there is room for further expansion. The introduction of Mobike is shown in Table1.

Table 1   Profile of Mobike

Enterprise Name	Beijing Mobike Technology Co., Ltd		
Founding time	2015	Location of Formation	Beijing City
Service User	Over 2Billion people	Service Area	Over 180 cities,9 countries
Brand Name	Mobike	Business Scope	Smart Shared Bicycle Service
Honors	Earth Guardian Award Sustainable Urban Transport Special Award The China's 50 Most Influential Brands in 2017 The 50 companies that are changing the world in 2017 The China's Most Innovative Enterprise in 2016		

Data Sources: https://mobike.com/cn/

3.2 Analysis on business mode innovation of Mobike

1) Accurate target market segmentation. The main target market of Mobike consists of three parts. One is office worker, the other is urban resident, and the other is university student. In big cities, traffic congestion has always been a huge pain point, so the short-distance travel is absolutely rigid and high frequency demand. Mobike forms effective complementarity with subways, buses, taxis, and Uber express. The Statistics show the scale of Chinese bicycle-sharing market exceeded 10 billion RMB in 2017, and it is estimated that the bicycle-sharing market in China will exceed 17 billion RMB in 2018. Chinese bicycle-sharing market order over 50 million units per day, and the orders of Mobike over 20 million units per day Mobike is committed to solving the "last mile problem" for users, in fact, Mobike does it. The Market Situation of Chinese Bicycle - Sharing is shown in Table2.

Table 2   Market Situation of Chinese Bicycle - Sharing

	Mobike	OfO	Hellobike
Market Share	56.56%	29.77%	8.66%
Orders Units per Day	over 21 million	over 10 million	over 3.2 million

Data Sources: 《Domestic Bicycle-Sharing Market Research Report for the First Quarter of 2017》 The Sootoo Institute

2) Significant technological advantages. Mobike uses new design, materials and manufacturing processes with over 30 patents than traditional bicycle. Firstly, the weight of the body and wheels of new product are greatly reduced in order to make riding easier and more efficient. Mobike makes seats for new bikes easier to adjust in order to increase comfort. Secondly, Mobike also makes significant progress at the safety level, the new product is used a new high-performance, long-life braking system which greatly improves safety performance. Thirdly, Mobike independently researchs and developes the world's first smart pileless bicycle-sharing with smart lock. PS enabled Mobike allow users to locate the

bikes on the map and help to navigate their path to the exact location of the bike. Chinese mobile phone users can scan the QR (Quick Response) code on the Mobike bicycle of bike-lending service on a road. Can you always know where the nearest Mobike is on the phone? Mobike can ensure that the actual positioning error does not exceed 30cm.

3) Unique Profit mode. The profit mode refers to the income structure, cost structure and corresponding target profit of the company divided by stakeholders. Firstly, the app requires real-name registration with phone number, ID card and a deposit like other apps, but the deposit varies from 299 RMB for Mobike, 199 RMBfor Xiaoming Bike and 99 RMB for OfO. Mobike receives a large number of deposits. Mobike can receive 80 million non-risk interest income from deposits in one year and form a huge "fund pool" through deposit rules (ZhaiYEhu, LiuTian, 2017). Secondly, Mobike earns income through bikes rentals. Xiaoming Bike's cheapest price is 0.1 RMB for 30 minutes. OfO 's cheapest price is 1 RMB per hour, but offers a discounted rate of 0.5 RMB per hour for students. Mobike is the most expensive at 1RMB for 30 minutes. Mobike's average daily usage time has approached 11 million minutes. Thirdly, Mobike promotes economies of scale by creating huge volume and reducing production costs of bicycles, creating cost and price advantages.

4) Ambitious vision and mission. Mobike provides smart bicycle-sharing services at affordable prices for everyone, and makes people more convenient to complete short-distance travel in the city. Mobike help reduces traffic congestion, reduces environmental pollution and makes our life better. The vision and mission reflect the value proposition of Mobike.it includes low price, energy saving and environmental protection, sharing and development.

5) Harmonious relationship among important partners. The government, bicycle manufacturers and financial companies are important partners to Mobike. Firstly, Mobike explores various cooperation ways with government, communities and partners to solve industry bottlenecks with innovative technologies. Mobike utilizes its own technology bases and advantages to set smart Mobike preferred location (SMPL), Mobike's work wins support and appreciation from governments in Beijing, Shanghai, Guangzhou, Shenzhen. Chinese Premier Li Keqiang praises Mobike as a spring breeze in 2017.Secondly, as an innovative leader in the smart bicycle-sharing industry, Mobike attaches great importance to the selection and management of members of manufacturing industry chain. The Foxconn Group, The TSRC company, MERIDR, XDS, HANGERY, BATTLE are important suppliers to Mobike. Thirdly, as a growth company, Mobike needs a lot of money to maintain the company's operations and development., it cannot be the ultimate winner without strong capitals as support. In the past three years, Mobike wins many rounds of investment which establish the foundation for the company's continuous innovation and rapid development.

4 Comments and Suggestions

1)Mobike should serve more market segments which rely on technological research and development capabilities. Firstly, it must have a clear comparatively competitive advantage in comparison with similar companies, so it is necessary to provide different types of service according to the needs of different customers. Such as add Chinese and English switching in app for foreigners, add temporary lock function, add daily rent function, the reserved bicycles should be marked in the app. Secondly, the number of vehicles and the efficiency of dispatch are the two most important factors for the users. Mobike should further reduce body weight and improve customer riding experience.

2)In order to consolidate and increase market share in the fierce bicycle-sharing market, Mobike needs sufficient funds for bicycle production and market operations, so investors become important partners in the development of Mobike. Mobike raises over US\$ 1 Million in series of financing round from 2015 to 2018.The introduction of capitals strengthen the power of the enterprise and is conducive to the expansion of the enterprise, but it also leads to the weakening of the decision-making power and control of the company's executives. Mobike must strengthen relationship with many investors and seek financial assistance from government.

3)Mobike faces a series of non-market problems that increase urban management difficulties, such as bicycles destroyed, bicycles stealed and uncivilized parking (arbitrary parking, arbitrary abandon, arbitrary cross the road, escape payments). Mobike should further strengthen cooperation with the government to reduce the damage to bicycles. Such as improves credit management system, introduces industry regulations, strengthens public education and improves penalties.

4) Firstly, Scale is an important factor in the leasing market competition, Mobike launches a huge bicycle in order to ensure the market position, but the cost of each Mobike bicycle is more than

2000RMB, so the investment cost is alarming. Secondly, Mobike charges 1RMB for 30 minutes and it is hard to realize profitability with low prices, so advertising and data mining are the main source of future profit. For one thing, Mobike bicycles are also a mobile advertising medium like buses and subways, the advertising revenue will be very sizable with the large number of bicycles and a wide distribution. For other thingummies should make full use of data mining to analyze users' travel time and behavior habits and recommend matching products for users.

5 Conclusion

This article uses literature research and case studies to describe and analyze the internet mobile business mode innovation of Mobike. The paper reviews and comments on the main types of modes based on the domestic and foreign literatures from 1996 to 2018.The paper elaborates the characteristics of mobile internet business mode and describes the factors that influence business mode innovation. The research shows features of its business mode include accurate target market segmentation, significant technological advantages, unique profit mode, ambitious vision and mission, harmonious relationship among important partners. Although Mobike integrates internet of things, mobile internet and electronic payment technologies which meet the needs of the "last mile" in people's travel, but the current business mode still needs to be further optimized, such as serve more market segments through product innovation and service innovation, further strengthen relationship with many investors and seek financial assistance from government, further strengthen cooperation with the government to reduce the damage to bicycles, advertising and data mining are the main source of profit.

Through case study, it was found that technical factors, product factors, organization factors, and market factors played an important role in the business mode innovation process of Mobike. The business mode innovation of Mobike is a radical innovation compared with traditional business modes, but the process of innovation is continuous. This article analyzes the mobile internet business mode by using exploratory research with a single case, the next step of research work can be carried out from the comparative analysis of multiple cases, and it can also be started from the perspective of exploring the mechanism.

Measurement of the Status and Its Influencing Factors on China's Service Industry in Global Value Chain

Huang Ying, Dong Jiali

School of Economics and Management, Wuchang Shouyi University, Wuhan, P.R.China, 430064

(E-mail: grace.00123@aliyun.com, karrydongjl@163.com)

Abstract: In this paper, we describe the status quo of Chinese service trade, estimates sophistication of Chinese service exports on the basis of data from 20 economies during the period from 2004 to 2015, and then measures the specialization position of Chinese service industry in global value chain (GVC). We find that Chinese service exports play an increasingly important role in the world as well as its sophistication index is growing, but the technical content of exports is relatively lower and Chinese service industry is still at the low end of GVC. Finally, we analyze the factors affecting the status of service industry in GVC and propose the suggestions to promote the value chain upgrading of Chinese service industry.

Key words: Service industry; Global value chain; Export sophistication; Influencing factors

1 Introduction

As Chinese service exports are enjoying an explosive growth, China has become the 5th largest exporter of service products in the world in 2016. A growing number of literature has begun to study on the status of China's service industry in GVC. The concept of sophistication was proposed in 2003 and usedto reflect the technological structure of a country's export commodities. The export sophistication can reflect the position of a country's certain industry in international division of GVC(Hausmann, 2003).Based on export sophistication measurement of manufacturing by Hausmann et al. (Hausmann et al.，2007), Mishra et al. (Mishra et al.， 2011) proposed a method for measuring the technical complexity of service exports. At home, the index was firstly employed to measure technological sophistication of China's service exports (Dai Xiang, 2012). It is discovered that the export sophistication of China's service industry is in the low-end of GVC(Yin Weihua, 2015; Li Huijuan and Cai Weihong, 2016; Meng Dongmei et al, 2017). The sophistication of Chinese service exports is constantly increasing, promoted by human capital, openness of service trade, per capita GDP, R&D expenditure, FDI utilization, foreign service intermediates and institutional quality(Yin Zhongming and Gong Jing, 2014; Zhang Yu and Dai Xiang, 2015;Li Huijuan and Cai Weihong, 2017).

In this paper, according to the Extended Balance of Payments Service classification(EBOPS2002), the service industry is divided into 11 categories, namely transportation, travel, communication services, construction services, insurance services, financial services, computer and information services, royalties and license fees, other business services, personal, cultural and recreational services and government services.

2 Status Quo of Chinese Service Trade

From the viewpoint of trade scale, according to the United Nations trade statistics, the China's total service trade rose from $66.43 billion in 2000 to $635.11 billion in 2016, an increase of nearly 10 times. Particularly, the total value of China's service exports rose from $30.43 billion in 2000 to $184.66 billion in 2016, with a6-fold increase. From the viewpoint of trade structure, China's exports mainly concentrate on travel, transportation and other business services, which accounted for 92 percent of total exports in services in 2016.On the whole, China's service trade is on the rise, with an increasing growth rate. Meanwhile, the export structure of China's service trade has gradually changed from traditional labor-intensive service exports to modern knowledge and technology-intensive ones. In the global value chain, the technological level of China's service trade lags behind developed countries, and its trade status remains to be improved.

3 Specialization Status Measurement of China's Service Industry in GVC

3.1 Construction of export sophistication

The export sophistication is used to analyze a country's export structure, and reflects technology content and the status in international labor division of export goods or services. The research applied the export sophistication based on Mishra (Mishra，2011) model to analyze the technology content and

the specialization position of China's service industry in GVC.

Firstly, the export sophistication in sub-service industry level is calculated as below.

$$PRODY_i = \sum_j \frac{x_{ij}/X_j}{\sum_j x_{ij}/X_j} Y_j$$

$PRODY_i$ is the export sophistication of sub-service industry i. It is a weighted average of the per capita GDPs of countries exporting a given sub-service industry. x_{ij} represents export value of sub-service industry i in country j. Y_j means GDP per capita of country j. The total service exports of country j equals $X_j = \sum_i x_{ij}$.

Secondly, the export sophistication of a country's service industry is calculated as followed.

$$EXPY_j = \sum_i \frac{x_{ij}}{X_j} PRODY_i$$

$EXPY_j$ represents export sophistication of the service industry in country j. It is a weighted average of the $PRODY$ for that country, where the weights are the value shares of the sub-service products in the country's total service exports. The EXPY index reflects technology competitiveness and status of industrial division of a country's service industry in GVC.

3.2 Data source

In view of data availability, based on Mishra (Mishra, 2011) model, among the world's top 25 economies in service exports in 2016, data of service exports in 20 countries or regions during the period between 2004and 2015 is chosen to measure export sophistication in the research. According to the data of UN conference on trade and development (UNCTAD),total service exports of 20 countries or regions contributed more than 62% to world's exports. Thus, the sample data is representative. Trade flow data of the service and sub-service industries in 20 economies is obtained from the United Nations trade statistics database(UNCOMTRADE) and GDP per capita is from the world bank database(DATABANK).The GDP per capita is in U.S. Dollar on the base year of 2004.

3.3 Result analysis

3.3.1 The export sophistication of China's service industry

Table 1 shows the sophistication of China's service industry is rising from $29812 in 2004 to $31532 in 2015in a fluctuating way, peaking at $37111 in 2011. The index is increasing with an average growth rate of 0.74% per year, reaching the highest growth rate of 8.78% in 2007.It is growing during the period between 2004 and 2008, and waving after financial crisis. A big decline occurred in the year of 2009 and 2012, which was caused by the financial crisis shock in 2008 and world trade slowdown in 2012.

Table 1   Sophistication Change of China's Service Industry from 2004 to 2015   Unit: US $

2004	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015

Data source: calculated based on data from UNCOMTRADE.

The technological sophistication of service exports in China and developed countries shows a fluctuated rising trend, which is affected by the world economy. In the year of 2009 and 2015, the global demand is insufficient due to the financial crisis and the decline of the world economy. The economic and technological development is slowing down, which has seriously affected world servicestrade, directly led to a decline in sophistication of service exports in various countries.

The four developing countries show a fluctuated rise in service export sophistication, with China's index lower than that of Russia, but far higher than that of Poland and India. With abundant oil and gas resources, Russia has a strength in the military industry and science and technology, thus led to higher index than China.I ndia's computer and information service industry are well developed, with its exports accounting for an average percentage of 48% to the total service exports from 2004 to 2015.But India's service exports and GDP per capita are lower than China's, thus with the lower index.

In general, China's service exports are increasing rapidly, however, its export sophistication ranked 17th in 20 sample countries or regions. Therefore, In the fierce competition of international service market, China's service trade is in the low-end and downstream position in GVC.

3.3.3 The average sophistication of sub-service exports in 20 economies and China's service industry's status

Based on the first formula, the average export sophistication of 11 sub-item services in 20 economies from 2004 to 2015can be calculated. By comparison of 11 sub-service industries' indexes, modern sub-service industries with high added value such as financial services, insurance services, personal, cultural and recreational services, royalties and license fees have high export technical level, ranked top four. The traditional sub-service industries such as transportation, travel, construction services have low technological level of the exports. Meanwhile, the high-end services with high added value, high capital and technical intensity, can promote the export sophistication and the status of national service industry in GVC. Therefore, it's necessary for a country to speed up the development of high-end services to improve technological level of service exports and its GVC status.

Table 3   Export Share Change of Chinese Sub-service Industries from 2004 to 2015

Sub-service industry	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015	mean
Transportation	0.186	0.207	0.228	0.256	0.261	0.182	0.211	0.191	0.203	0.205	0.182	0.147	0.205
Travel	0.397	0.394	0.369	0.305	0.278	0.306	0.283	0.261	0.261	0.281	0.270	0.435	0.320
Communications services	0.008	0.007	0.008	0.010	0.011	0.009	0.008	0.009	0.009				0.009
Construction services	0.023	0.035	0.030	0.044	0.070	0.073	0.089	0.079	0.064	0.058	0.073	0.063	0.058
Insurance services	0.006	0.007	0.006	0.007	0.009	0.012	0.011	0.016	0.017	0.022	0.022	0.019	0.013
Financial services	0.001	0.002	0.002	0.002	0.002	0.003	0.008	0.005	0.010	0.017	0.022	0.009	0.007

Continual Table 3

Sub-service industry	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015	mean
Computer and information services	0.025	0.025	0.032	0.036	0.042	0.050	0.057	0.065	0.076	0.093	0.096	0.093	0.058
Royalties and license fees	0.004	0.002	0.002	0.003	0.004	0.003	0.005	0.004	0.005	0.005	0.003	0.004	0.004
Other business services	0.344	0.313	0.315	0.331	0.315	0.352	0.322	0.365	0.348	0.311	0.327	0.222	0.322
Personal, cultural, and recreational services	0.001	0.002	0.001	0.003	0.003	0.001	0.001	0.001	0.001	0.001	0.001	0.003	0.001
Government services	0.006	0.007	0.006	0.005	0.005	0.007	0.006	0.004	0.005	0.007	0.005	0.004	0.005

Data source: calculated based on data from UNCOMTRADE.

Table 3 shows the top three China's sub-service industries in average export share are other business services (32.2%), travel (32%) and transportation (20.5%). The last four sectors are personal, cultural, and recreational services (0.1%), royalties and license fees (0.4%), government (0.5%) and financial services (0.7%). In 2015, travel, other business and transportation services accounted for 80.4% of China's total service exports, while financial services, government services, royalties and license fees, personal, cultural, and recreational services, accounted for only 2.0%. Therefore, China's traditional sub-service exports with low technological level account for a major part of total service trade. However, modern sub-service exports with high added value and technology intensity account for a small proportion, thus led to the low technological level of China's service trade and its low position in GVC.

4 Influencing Factors of Status of China's Service Industry in GVC

The status of Chinese service industry in GVC is mainly influenced by following factors.

4.1 Human capital

China's service trade is dominated by the labor-intensive traditional service industries. The development of moderrn service industries, with knowledge, technology and capital intensity, are relatively backward. Human capital can be vigorously developed and used to transform export structure from traditional service industries into modern ones. On one hand, human capital helps to increase service output and service exports. On the other hand, human capital promotes technological innovation in service industry, expanding the types and channels of service trade, and optimizing the technical structure of service exports. To some extent, human capital represents the accumulation and abundance of knowledge and technology in a country, and determines the sophistication and technical level of service exports.

4.2 Scientific and technological level

The improvement of scientific and technological level, on one hand, enables enterprises to provide better service with less labor; on the other hand, helps to improve the quality and skills of workers, which enhances labor efficiency, thus reducing operating cost and increasing service outputs. In addition, the technology upgrading will refine social division of labor and production specialization, thus giving rise to emerging service sectors with technology intensity. The technological level of service exports can effectively promote by resources continuously flowing to these new service industries.

4.3 Scale of service trade

The scale expansion of service trade can effectively improve technological level of service exports. Service trade is the extension of service industry, the development of which directly affects the ability of a country to provide services to the international market. Developed countries' service industry, in the upstream position in the GVC, accounts for about 80% of GDP, and its trade development is key to improve a country's international competitive position. The scale of service trade plays an important role in optimizing service export structure. With trade scale expands, service trade will gradually show economies of scale, which helps enterprises to reduce production cost and invest more money and resources in the high-end services, thus improving the technology content and added value of service products as well as its export sophistication.

4.4 Service trade policy

Government's policy is essential to the development of service industry. The preferential and supportive policies will guide human capital, money and social resources to the industry, create a good

developing environment in tax burden, supervision, and financing, and foster emerging service industries by encouraging innovation. At present, Chinese government attaches great importance to the development of service trade and promotes it as a national strategy. Firstly, open trade policies reduce enterprises' production and transaction costs, and promote the participation of a country's service sector in global trade competition. Thus, the technological level of service exports will be raised quickly. Secondly, open policies are conducive to attracting direct investment from multinational service companies, which brings about advanced technology and management experience, upgrading the technical level of domestic service exports.

5 Conclusion

The research uses export sophistication index to measure the status of China's service industry in GVC and draws the conclusion as followed. China's service exports enjoy rapid growth, bringing about increasing technical content. However, the sophistication is not so high because Chinese exports in service industry mainly rely on traditional services with low technical requirements rather than modern services with high technology contents. In the background of international labor division, China embeds itself in GVC with advantage of labor resource, but is locked in the low-end due to the lack of advanced technology and innovation. The following suggestions are put forward to promote the upgrading of China's service industry in GVC.

Firstly, to improve IPR system, increase R&D and talent investment. The independent innovation ability of advanced technology must be enhanced, and IPR ownership must be increased to maintain the sustainable growth of Chinese service industry. Perfect IPR system helps to provide a good environment for independent innovation, encouraging service enterprises to use core technology to gain market share and to embed themselves in the industrial chain. R&D and talent investment should be in creased to improve enterprises' absorption ability of technology spillovers and upgrade the value chains of China's service industry.

Secondly, to expand the openness of service trade and optimize service exports structure. According to the results, China exports less service products of high sophistication and more service goods of low sophistication.

Thus, most Chinese service exports are less-skilled middle and low end products. In the future, China should actively implement diversified strategy of upgrading the technological level of service exports. China's service exports should focus on modern industries such as financial services, insurance services, royalties and license fees, personal, cultural and recreational services, computer and information services, and government services, which enjoy high export sophistication and output per capita. China should also develop export potential and increase added value in the traditional service industries through modern technology. Technical content improvement should be emphasized rather than scale expansion to optimize the export structure of service industry.

Finally, to improve policies and regulations, strengthen top-level design and macro-control of service trade. China's government should attach great importance to talents cultivation, foreign capital introduction and technical innovation in service industry. Multinational service corporations should be introduced by preferential policies, technological innovation should be strengthened by IPR protection and innovative talents should be both self-cultivated and introduced to enable China's service industry extending to high value-added industrial chain. In addition, China should build innovative industrial demonstration park of high-end service industries to increase the export sophistication by spending sufficient R&D investment in modern service industries, rationally optimizing resources allocation, and improving innovative infrastructure construction and information technology networks. The innovation of high-end service industries can promote the upgrading of service industry and service trade, and feed back the low-end service industries.

On the Development Countermeasures of the University Industrial Research Institute Based on "One Axis and Three Helix" Innovation Mode

Yuan Dachao, Hu Jian
Technology Cooperation and Achievement Transformation Center, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: 1976968042@qq.com, 5829814@qq.com)

Abstract: The study mainly uses the documentation research method and the comparative analysis method to discuss the construction mode, operating mechanism, resource allocation and talent training of the University Industrial Research Institute. It puts forward the construction of the university industry based on "One Axis and Three Helix" innovation mode. The institute's strategy is to take the "axis" of the enterprise development as the core, giving full play to the advantages of the "three helix" of government, universities, and agencies, complement each other's strengths, realize organic combinations of various production factors such as talents, capital, and information, and thus promote the sound development of the university's industry research institute.
Key words: The development countermeasures; The university industrial research institute; "One Axis and Three Helix" innovation mode; Construction

1 Introduction

As a bridge and link between universities and places, the University Industrial Research Institute inherits and continues the university's scientific and technological innovation functions. It is also closer to the needs of local industries and plays an important role in university research activities and local industrial technology innovation activities. At present, the number of overseas science and technology transformation institutions set up by universities themselves and built jointly with local governments or enterprises has grown rapidly and in various forms, but their technological transformation functions have not been fully realized. Based on this, this paper intends to further explore the development mode of the University Industrial Research Institute through the perspective of the "One Axis and Three Helix" innovation mode.

2 Construction Model and Problems of the University Industrial Research Institute

The University Industrial Research Institute is generally supported by local governments and universities. It focuses on the scientific research, teaching, and management of the university and integrates scientific and technological achievements such as "politics, production, learning, research, and use". It is a platform organization and service organization integrating scientific and technological innovation and entrepreneurship, professional personnel training and other functions.

2.1 Construction Mode of the University Industrial Research Institute

2.1.1 Government-driven Mode

In this mode, it includes various topics such as government, universities, and companies. The cooperation between the various entities is relatively close. The government plays a role in decision-making, coordination, management, assessment and supervision, and information exchange services. Universities and research institutes play a central role through scientific research capabilities, and companies actively participate.

2.1.2 Enterprise-led Mode

In this mode, enterprises are in a dominant or core position. Universities and research institutes actively participate in the research and development of enterprises. The government mainly provides policy support and the construction of a legal environment. Social intermediary agencies are actively providing various services. This type of mode is conducive to enhancing the company's technological innovation capabilities and competitive advantages. The enterprise-led mode can timely obtain market demand and change information and achieve market-oriented goals. This mode is an important way for the industrialization of scientific and technological achievements.

2.1.3 Cooperation and Cooperation Mode

It is an organizational mode in which universities, research institutes, and enterprises work together

to share risks. Universities and scientific research institutions provide technical achievements, research strength, and talent support. Governments or companies provide funds and test sites. The government provides comprehensive laws and regulations and with quality services, intermediaries serve as a bridge for all parties through the provision of market information and other services. The rights, interests, and risk sharing of all parties are determined by the contract. This is the most important form of China's current university industry research institute.

2.2 Problems of the University Industrial Research Institute

The capital investment is insufficient, and the industrialization of scientific and technological achievements is not perfect. To achieve a smooth process of technology from production to industrialization, this process needs to be completed in four stages, including: market forecasting, technology research and development, results transfer, and industrialization. The main responsibilities of the University Industrial Research Institute should be the scale-up and engineering improvement of scientific and technological achievements. However, this process requires sufficient funds to support the premise and guarantee. The ratio of a scientific and technological achievement from scientific research to the formation of technical achievements, to the pilot phase and final industrialization is about 1:10:100. Due to insufficient funds and related supporting facilities, some university industrial research institutes are difficult to conduct scientific research, and the ability to achieve results in pilot and industrialization is limited. It is more difficult to achieve results transformation, resulting in a large number of semi-finished products waiting for the word, hindering its innovation power.

Inadequate human resources, innovation and development are not enough momentum. The University Industrial Research Institute is a comprehensive institution that includes technology research and development, technical services, venture capital, and capital operations. It not only requires excellent professional and technical personnel, but also requires complex technical management talents who are good at integrating various resources. It is necessary to understand the situation of university scientific research institutions and to be familiar with the local industrial situation. It is necessary to have both scientific research experience and industrialization experience. It is necessary to be able to understand scientific research culture and be familiar with corporate culture. The shortage of talented people is first and foremost the number of leading talents in science and technology is lacking, and the structural contradictions of talents are more prominent; the existence of these problems has become a constraint factor for the further development of the university's industry research institute.

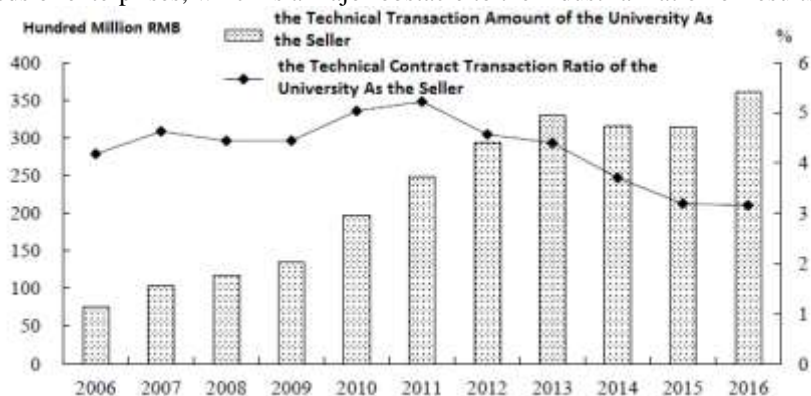
Hematopoietic capacity is not strong, and industrialization goals are not prominent. As shown in figure 1, from 2006 to 2016, the annual technical transaction volume of the universities as sellers was about 30 billion RMB, Accounting for 3-4% of the national technical transaction volume, it is relatively low proportion. The ultimate goal of the University Industrial Research Institute is the application of the market. Therefore, it should be closely integrated with the needs of the enterprise. That is, the goal of its technological research is to meet the needs of the enterprise and to regard it as the principle of industrial service. The government-supported research results should be commercially available technologies that can be applied to the industry to avoid the phenomenon that there are no results and no one wants to be. In order to avoid this phenomenon, it is necessary to require the active participation of enterprises in all aspects such as project declaration, research and funding. The current problem is that the selection of projects does not fully reflect the company's need for technology, which has led to some research from the actual needs of enterprises, which is a major obstacle to the industrialization of results.


Figure 1   The Technical Transaction Amount and the Technical Contract Transaction Ratio of the University as the Seller (2006-2016)

3 Connotation of "One Axis and Three Helix" Innovation Mode

The "one-axis, three-helix" innovation mode is based on the triple helix theory. The triple helix theory is an innovative theory put forward by Henry Eczkowitz and Lloyd Redstoff in 1995. It refers to the fact that universities, industries, and governments maintain their unique functions while supporting other the main body is constantly innovating, forming an interactive and reflexive, spiral-progressive relationship and building a university-industry-government analysis paradigm.

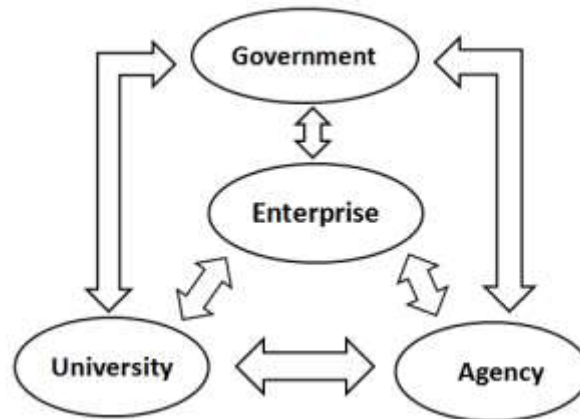
The triple helix theory solves the traditional "demand traction" or "technical impetus" for the transformation of linear patent achievements. However, there is still no effective solution to such problems as technological asymmetry and technological needs. The intermediary, with its own knowledge, technology, talents, information and other resources, plays a role of media and catalyst in the process of science and technology transformation, and is an important subject to resolve this "last mile". Therefore, the author proposed the "one axis and three helix" innovation mode.


Figure 2   The Innovation Mode of "One Axis and Three Helix"

The "one-axis and three-helix" innovation mode, that is, the axis of "enterprise" and the three spiral subjects of "university, government, and agency," will exert their respective advantages in the process of transforming scientific and technological achievements, focusing on each other but assisting and integrating each other to achieve technology. Accurate transformation of results. Specifically, as a market entity, enterprises mainly play the function of realizing the transformation of scientific and technological achievements, leading the realization of the transformation of scientific and technological achievements into the industrialization chain. As the source of intellectual resources, the university plays a major role in the creation of scientific and technological achievements in the entire transformation chain. Leading the transformation of scientific and technological achievements into the creation of a knowledge chain; the government, as a policy maker and executor, plays a major role in guiding, coordinating, and creating a good environment, leading the improvement of the policy chain for the transformation of scientific and technological achievements, and the intermediary agency as an outcome transformation linker. It mainly plays a role in precision guidance and boosting, leading the integration of scientific and technological achievements into knowledge chains, policy chains, and industrial chains.

4 Construction of the University Industrial Research Institute System of "One Axis and Three Helix" Innovation Model

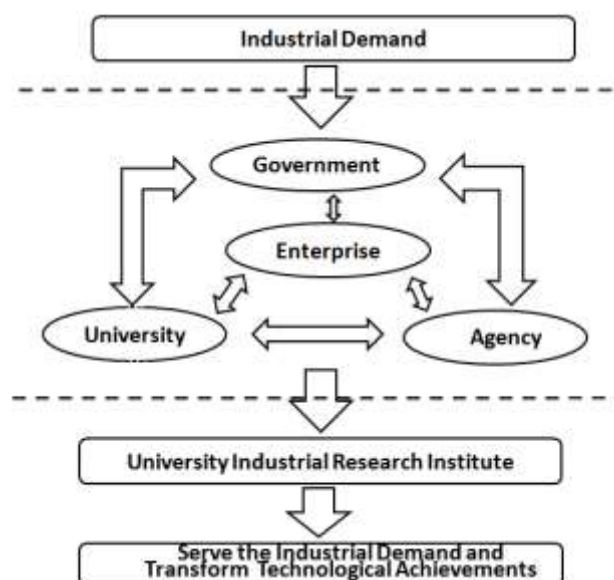
The "one-axis and three-helix" innovation mode has listed the university's industry research institute as an independent main body. Enterprises, governments, universities, and intermediary agencies are the core subjects of the university's industrial research institutes. In the process of co-construction, taking the "axis" of enterprise development as the core and giving full play to the advantages of the "three spirals" of the government, universities, and agencies, the parties complement each other's strengths, and various production factors such as talents, capital, and information will be organically combined. Effectively promote the sound development of the University Industrial Research Institute.


Figure 3   The University Industrial Research Institute Construction of
"One Axis and Three Helix" Innovation Model

4.1 Enterprise: Innovation Body

Enterprises to enhance their competitiveness through technological innovation is the most important means to increase the added value of their products. Enterprises should establish correct scientific and technological innovation values under the guidance of market demand, integrate scientific and technological innovation values into the development of university industrial research institutes, combine them with the economic benefits of the University Industrial Research Institute, and integrate with the core competitiveness. Science and technology innovation enhance the market risk-taking ability of the University's Industrial Research Institute.

4.2 Government: Leading Coordination

The government is the coordinator of the construction and development of the university's industry research institute. First, the government has formulated a series of macroeconomic policies such as financial subsidies to create a favorable environment for the development of the university's industrial academy. Secondly, actively guide the coordination of universities and colleges that have scientific research advantages in this field of technology, scientific and technological agencies with good credit status, and powerful companies to cooperate with the University Industrial Research Institute. Make the university industrial research institute more harmonious with companies, universities, and agencies in the process of cooperation.

4.3 University: Research and Development

The university has the advantage of talents and technology, and provides the university's industry research institute with abundant knowledge resources and is the main force. Universities should formulate relevant policies to encourage the industrialization of scientific researchers and enterprises. In addition, when translating scientific research results, it is necessary to actively integrate the resources of enterprises, governments, and science and technology intermediaries, formulate reasonable interest distribution methods and operational procedures, and use benefits as a link to effectively connect the participating entities and ensure the University's Industrial Research Institute. The effective operation.

4.4 Intermediary: Main Body of Information

As a participant in the market process and a promoter of the transformation process of scientific and technological achievements, the University Industrial Research Institute should strengthen the flow and smooth communication with the market information elements. The intermediary will use its own advantages to timely communicate the latest market information and technical resources to the University Industrial Research Institute. Openness, and the transfer of frontier market signals, enable the University of Industry Research Institute's scientific and technological achievements transformation process and personnel training to suit market demands and industrial development trends.

5 Conclusion

The development of the University Industrial Research Institute is a complex process with multiple links, mutual promotion, and multi-subject participation. This paper constructs an innovative mode of "one axis and three helix" The four main bodies of companies, governments, universities, and agencies are doing their best and interacting with each other. Strive to strengthen the shortcomings of intermediaries and make up for the lack of university industrial research institutes. This has important practical significance for improving the operational mechanism for the transformation of scientific and technological achievements in China.

yjdong02@163.com)

Abstract: The enterprise's innovative diagnosis is an important force to enhance the company's scientific and technological innovation capabilities and accelerate the transformation and upgrading of the company. This article takes enterprise's innovation diagnosis as the breakthrough point and constructs the innovation capabilityevaluation index systemof ST SMEs(the scientific and technological small and medium-sized enterprises) from five aspects: innovation input ability, collaborative innovation ability, innovation transformation ability, innovation management ability and innovation output ability. Finally puts forward the countermeasures and suggestions for improving the innovation ability of ST SMEs.
Key words: Innovation diagnosis; ST SMEs; Innovation capability; Innovation capability evaluation index system

1 Introduction

As an important force for technological innovation and a direct carrier for the transformation of technological achievements, technology-based ST SMEs have become an indispensable economic subject and innovation subject in China (Hu Xiaojin, 2010). To help excellent ST SMEs overcome the growing difficulties, the government should formulate targeted policies and measures to conduct reasonable guidance and support. This requires the establishment of a scientific innovation capabilityevaluation index system for enterprises. For ST SMEs, their level of innovation capability plays a decisive role in the company's production and business activities and further growth and development. The diagnosis of innovation capability of ST SMEs is significant to help governments formulate targeted policies and measures to enhance the innovation capability of ST SMEs.

2 Literature Review

2.1 Enterprise Innovation Diagnosis

Yu Wu introduced how to carry out enterprise innovation diagnosissystematically and elaborated on 16 aspects of enterprise management such as establishing a perfect company operation and agency mechanism(Yu Wu, 2013). Wang et al. summarized and extracted thetechnological innovation nodes diagnostic methods and types of technological innovation path and pointed out the application conditionsof these diagnostic methods and innovative path selection (Wang Yong, 2014). Kozioł et al. analyzed the evaluation results of innovation degree in the Malopolska region to find out thatthe decisive factors for innovation diagnosis were employee competence, modern infrastructure, cooperation in knowledge management, organization of work, and protection of knowledge (innovation) created within the organization (Kozioł L, 2015). Tomlinson et al. conducted an innovation assessment of the cooperative relationship within the multiple regression framework and found that ST SMEs ' innovation capability is an important driver of a series of production activities within the value chain(Tomlinson P R, 2013).

2.2 ST SMEs and Evaluation of Their Innovation Capability

So far, the concept of ST SMEs at home and abroad has not yet formed a unified definition. Feng Chaojun believes that ST SMEs are small and medium-sized enterprises that mainlyproduce, develop, and sell high-tech products, and are the most innovative and dynamic enterprisegroup in social and economic development (Feng Chaojun, 2016). Schumpete pointed out that innovation is "recombination of factors of production", that is, introducing a new combination of production factors or production conditions to the production system and establishing a new production function (Schumpeter J, 1934). Liu Guoyi et al. divided independent innovation dimensions according to the three interconnected and important aspects of the innovation chain and described the independent innovation capability of the clustered enterprises(Liu Guoyi, 2014). Larry pointed out that technological innovation can be measured

in terms of organizational capability, adaptive capacity, and many other aspects of the level of competence (Larry E, 1984).

This study, takingvarious factors into consideration, will build theinnovation capabilityevaluation index system of ST SMEs from five aspects: innovation input capability, collaborative innovation capability, innovation transformation capability, innovation management capability, and innovation output capability.

3 Constructionof Innovation Capability Evaluation Index System and Model of ST SMEs

3.1 Building Evaluation Index System

According to the "State Administration No. 115" (2017), this article systematically studies and summarizes the existing theories, and combines the actual situation of enterprise innovation development in Hubei, bases on the definition and characteristics of ST SMEs and comprehensively considers the various development stages of ST SMEsso that an innovation capability evaluation index system for ST SMEsis built (Figure 1).

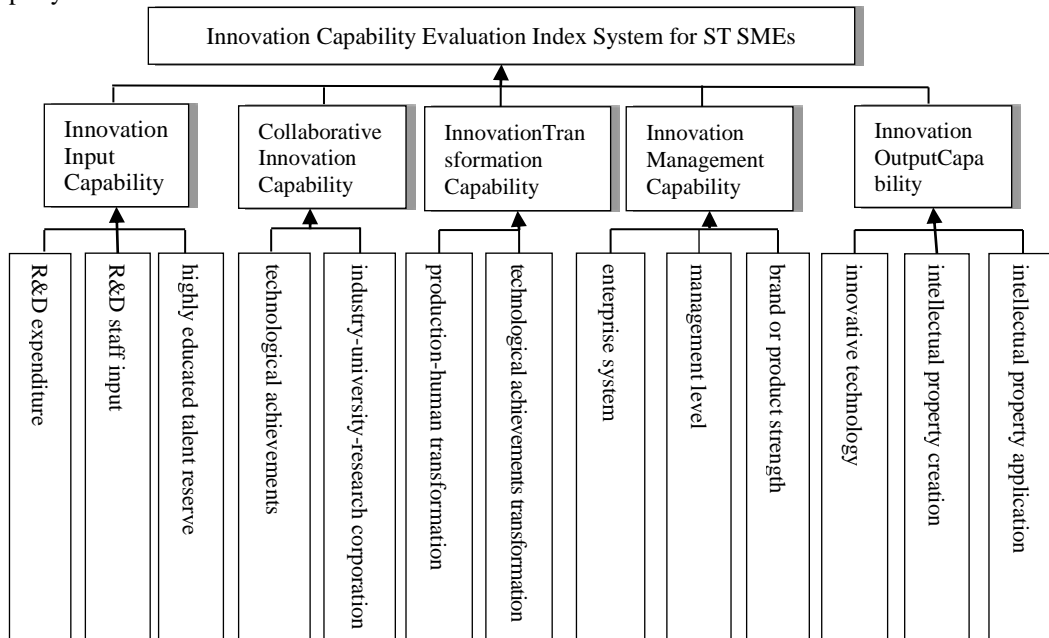
Innovation capability evaluation index system for ST SMEs includes the following: The first is innovation input capability of enterprises, that is, enterprises obtain production factors and invest in innovation activities, reflect the willingness and input of enterprises to carry out innovation activities, mainly including R&D expenditure and R&D personnel input; the second is collaborative innovation capability of enterprises, reflecting the ability of enterprises to use external innovation resources and carry out cooperation in production, teaching and research, including scientific and technological achievements and the cooperation of production, education and research; the third is innovation transformation capability of enterprises, which reflects the economic transformation efficiency of enterprise's innovation ability, including the transformation of enterprise product manpower and the transformation of scientific and technological achievements; the fourth is innovation management capability of enterprises, which reflects the ability of the enterprise to organize and manage innovative activities and mainly includes the enterprise system, management level and product or brand strength; the fifth is innovation output capability of enterprises, which reflects the direct results of enterprise innovation, including the technological level of innovation and the creation and use of intellectual property.


Figure 1   Hierarchy Analysis of Innovation Capability Evaluation Index System for ST SMEs

3.2 Establishment of Evaluation Model

3.2.1 Comprehensive Evaluation

The first step, each expert scores for the qualitative indicators one by one according to the actual

situation of specific enterprises; the second step, substituting the actual data of the company, calculating the scores of quantitative indicators and obtaining corresponding scores; the third step is to calculate the scores of innovation input capability, collaborative innovation capability, innovation transformation capability, innovation management capability, and innovation output capability respectively; the fourth step, the scores of these five innovation ability evaluations are weighted to obtain the total score of the enterprise's innovation capability evaluation (GuoCaiyun, 2013).

The calculation of enterprise innovation capability evaluation index is

$$X = x_1 f_1 + x_2 f_2 + ... + x_n f_n = \sum_{i=1}^{n} x_i f_n \qquad (1)$$

where X is the total score of the enterprise innovation ability, x_i is the score of each index, and f_i is the corresponding weight of each index.

Substituting a specific ST SME data into the formula (1) obtains the company's comprehensive score. According to the survey, the scores of ST SMEs with outstanding innovation ability are concentrated in more than 80 points, general innovation ability in 60-80 points, and qualified innovation ability below 60 points.

3.2.2 Determination of Weights

Through interviews with related experts, this paper averages the results of expert ratings and obtains a corresponding judgment matrix. Then the paper uses the common calculation process of AHP, and obtain the weight and consistency ratio of each judgment matrix, and subdivides it into third-class index according to each second-class index. In order to determine the scores of the index, the author consults relevant ST SMEs' identification, and draws on the relevant research results to obtain evaluation index weights and the evaluation criteriaof innovation capability for ST SMEs (Table 1).

Table 1　Innovation Capability Evaluation Index System for ST SMEs

First-class index	Weights	Second-class index	Third-class index	Weights	Evaluation criteria
Innovation input capability	0.2535	R&D expenditure	Enterprise R&D expenditure intensity	0.0623	Enterprise R&D expenses/sales revenue ≥6%, 100 points; 4%~6%, 80~100 points; 2%~4%, 60~80 points; ≤2%, 0 points
			Enterprise R&D expenditure growth rate	0.0436	≥15%, 100 points; 10%~15%, 80~100 points; 5%~10%, 60~80 points; ≤5%, 0 points
		R&D staff input	Enterprise R&D staff input intensity	0.0956	Number of R&D personnel/total number of employees in the enterprise ≥30%, 100 points; 20%~30%, 80~100 points; 10%~20%, 60~80 points; ≤10%, 0 points
		Highly educated talent reserve	Proportion of highly-educated personnel	0.052	Total number of master graduates/workers in the enterprise ≥50%, 100 points; 40%~50%, 80~100 points; 30%~40%, 60~80 points; ≤30%, 0 points
Collaborative innovation capability	0.1077	Technological Achievements	Science and technology project level and quantity	0.0310	One or more national science and technology innovation projects, 100 points; one provincial-level technological innovation projects or two municipal-level technological innovation projects, 80 points; one municipal-level technological innovation project, 60 points
		Industry-university-research cooperation	Number of industry-university-research cooperation projects	0.0389	≥ 3 items, 100 points; ≥ 2 items, 80 points; ≥ 1 item, 60 points
			Number of R&D institutions	0.0378	≥15, 100 points; 10~15, 80~100 points; 5~10, 60~80 points; otherwise, 0 points
Innovation transformation capability	0.1421	Production-human transformation	Innovative product share	0.0423	Innovative product sales/total sales ≥30%, 100 points; 20%~30%, 80~100 points; 10%~20%, 60~80 points; ≤10%, 0 points
			Staff productivity	0.0398	Total profit/total number ≥25,100 points; 20~25, 80~100 points; 15~20, 60~80 points; ≤15%, 0 points

Continual Table 1

First-class index	Weights	Second-class index	Third-class index	Weights	Evaluation criteria
Innovation transformation capability	0.1421	Technological achievements Transformation	Technological development capability	0.0278	Number of technical development contracts/total number of contracts ≥60%, 100 points; 40%~60%, 80~100 points; 20%~40%, 60~80 points; ≤20%, 0 points
			Technical service capability	0.0153	Number of technical service contracts/total number of contracts ≥30%, 100 points; 20%~30%, 80~100 points; 10%~20%, 60~80 points; ≤10%, 0 points
			Technical sales capability	0.0169	Number of technical sales contracts/total number of contracts ≥30%, 100 points; 20%~30%, 80~100 points; 10%~20%, 60~80 points; ≤10%, 0 points
Innovation management capability	0.1237	Enterprise system	Innovation environment	0.0392	Excellent enterprise innovation environment, forming a good enterprise culture, 100 points; enterprise innovation environment is good, there is an enterprise culture, 80 points; enterprise innovation environment is poor, enterprise culture, 60 points
			Enterprise innovation incentive system	0.0224	The enterprise innovation incentive system is perfect, the design is scientific and reasonable, 100 points; the enterprise innovation incentive system is relatively complete, the staff turnover is stable, 80 points; the enterprise has established an innovation incentive system, 60 points
		Management level	Systematic management of intellectual property	0.0184	The enterprise has specialized intellectual property management institutions or personnel, and the implementation is good, 100 points; the company has a special intellectual property management personnel, has a certain role in promoting, 80 points; companies have intellectual property management personnel, 60 points
			The efficiency of enterprise management system	0.0122	The enterprise has a complete management information system, with a rational design and efficient operation, 100 points; the enterprise has a management information system, which has a certain promotion effect, 80 points; the enterprise has no information management system, 60 points
		Brand or product strength	Enterprise brand or product level and quantity	0.0315	The enterprise contains one national or two provincial- and ministerial-level brand or product, 100 points; one provincial- and ministerial-level brand or product, 80 points; one municipal-level brand or product, 60 points
Innovation output capacity	0.373	Innovative technology level	Inventions, proprietary technology and patents per person	0.0774	Number of patents per person = 0.1, 60 points; for every additional 0.01 plus 10 points, each point is deducted by 0.01 for 10 points, and the total score is no more than 100 points
			Advancement of product technology	0.0636	Leading international level, 100 points; Internationally advanced level, 90 points; Domestic or industry leading level, 80 points; Domestic or industry advanced level, 70 points; Provincial leading level, 60 points; Provincial advanced level, 50 points

First-class index	Weights	Second-class index	Third-class index	Weights	Evaluation criteria
Innovation output capacity	0.373	Intellectual property creation	Enterprise authorized patent ratio	0.0589	The number of patents authorized by the enterprise accounts for the number of patent applications ≥80%, 100 points; 70%~80%, 80~100 points; 60%~70%, 60~80 points; ≤60%, 0 points
			Enterprise invention patent ratio	0.0714	The proportion of enterprise invention patents to total authorized patents is ≥90%, 100 points; 80%~90%, 80~100 points; 70%~80%, 60~80 points; ≤70%, 0 point
		intellectual property application	Enterprise implemented invention patent ratio	0.0523	The percentage of implemented invention patents as total invention patents = 100%, 100 points; 90%~100%, 80~100 points; 80%~90%, 60~80 points; ≤80%, 0 points
			Level and number of authorized patents	0.0494	1 or more class I intellectual property, 100 points; 4 or more class II intellectual property, 80 points; 3 class II intellectual property, 70 points; 1 or 2 class II intellectual property rights, 60 points [1]

Note: 1. The intellectual property rights are evaluated by classification, among which: invention patents, new plant varieties, national crop varieties, national new drugs, national grade one protected species, and integrated circuit layout design exclusive rights are evaluated according to Type I; utility model patents, design patents and software copyrights are evaluated according to category II

4 Innovation Diagnosis Process for ST SMEs

4.1 The Stage of Comprehensive Understanding

This phase includes data collection, in-depth interviews, and questionnaire surveys. The beginning of enterprise's innovation diagnosis, mainly through the Internet, or other organizations to review the company's information, makes a comprehensive understanding of the company. Among them, data collection includes industry data collection, regional data collection, product development status collection, and internal enterprise data review (current organization chart, existing job setup, business process system, financial statistics report, etc.). Then conduct in-depth interviews with high-level and basic-level employees of the company, design scientific and reasonable questionnaires that suit the actual situation of the company's customers according to the customer's needs and conduct questionnaire surveys to understand the management status of the company from multiple perspectives.

4.2 The Stage of Evaluation and Analysis

This stage includes status presentation, analysis issues, and benchmarking. Through the integration of collected data and feedback from interviews and questionnaires, the current status quo of enterprises is analyzed by the evaluation index system of innovation ability of ST SMEs, and the existing problems of enterprises in terms of innovation are expounded.

4.3 The Stage of Suggested and Countermeasures

Through the first two phases of work, a preliminary diagnosis of the enterprise was conducted. After innovation capability evaluation index system for ST SMEs was confirmed, it was calculated that the enterprise was at the level of innovation capability, and specific problems were analyzed from the criteria level indicators. Relevant countermeasures are proposed according to these issues, so as to solve problems in a targeted manner.

5 Measures to Improve Innovation Ability of ST SMEs

Through the analysis and evaluation of the innovation ability of ST SMEs, this paper puts forward the following countermeasures to enhance the innovation ability of ST SMEs.

5.1 Guide Enterprises to Increase R&D Investment

R&D activities are the core of innovation in ST SMEs. Compared with Japan, Sweden, Germany, and other developed countries, ST SMEs in China generally have problems such as lack of R&D institutions, shortage of R&D personnel and R&D funds. This directly weakens the company's ability to innovate. Therefore, Chinese business operators should pay full attention to the important role of innovation in the economic growth of enterprises, and increase investment in R&D equipment, R&D personnel, and R&D funds.

5.2 Accelerate the Establishment of a Sound Mechanism

At present, the management capabilities of China's ST SMEs are still relatively weak, and the organizational structure is still not perfect. Therefore, enterprises should speed up the establishment and improvement of the independent innovation incentive mechanism, risk prevention mechanism and supervision mechanism, establish a flexible organizational structure suitable for their development. At the same time, ST SME operators should also learn from the experience of foreign SMEs, establish a modern enterprise system with clear property rights and clear responsibilities, and attract investment funds from venture capital institutions to solve the problem of poor financing channels.

5.3 Create a Good Policy Environment

Government departments should create a favorable policy environment for Chinese ST SMEs, improve protection policies such as tax incentives and government procurement, increase support for technology incubators, advocate and encourage cooperation between industry, universities and research institutes, provide corresponding support for ST SMEs. At the same time, the government should also take effective measures to promote the development and improvement of the second board market, making it a capital market with sufficient depth and breadth to overcome innovative obstacles such as the shortage of funds and financing difficulties for China's ST SMEs.

6 Conclusion

The importance of innovation in the survival and development of SMEs is unquestionable, so innovative diagnosis of SMEs is crucial. This paper takes enterprise's innovation diagnosis as the breakthrough point and constructs the innovation capability evaluation index system of ST SMEs from five aspects: innovation input ability, collaborative innovation ability, innovation transformation ability, innovation management ability and innovation output ability, and finally puts forward the countermeasures and suggestions for improving the innovation ability of ST SMEs. This article mainly constructs a kind of innovation capability evaluation index system of ST SMEs, enriching the theoretical and applied research on the evaluation of innovation ability of ST SMEs.

Research on Constitution, Measurement and Evolution of University Innovation Field

Feng Kun, Zhang Fusong
School of Civil Engineering and Architecture, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: fengkun@whut.edu.cn, tj_peter@163.com)

Abstract: Innovation is the soul and motive force of university growth; it also is the historical mission of university. So innovation theory research is the major issue related to its survival and development. There is an important transition from the analytical paradigm to and field paradigm in the method of research on university innovation management which adopts a wholly thought on innovation system. The purpose of this paper is to answer what the composition of university innovation field space is, how do we measure it, how does it work and how does it evolve. Firstly, this paper builds the 3-dimensional field space of university innovation; Then this paper comprehensively expounds the measurement of university innovation field by using vector analysis and field theory; In addition, this paper discusses the innovative potential difference, field force, field intensity and innovative energy flowing; Finally, this paper studies its operation and evolution. It come to a conclusion that the innovative energy flows from the high potential energy node to the low potential energy node under the action of innovation field forces and innovation field shows self-strengthen process of path dependence and cumulative causation. the innovative points of the paper are that based on the university innovation field space with subject system dimensions, object system dimension, environmental system dimension has been constituted by defining innovative energy and innovative energy node, the innovation field operative mechanism and the evolution laws have been revealed and the new ideas and method have been provided for university innovation management.

Key words: University innovation field; Innovative energy flowing; Space constitution; Measurement; Operation system; Dynamic evolution

1 Introduction

Innovation is the soul and the power of university growth. Since American economist Schumpeter came up with "innovation theory" in his works "the theory of economic development" in 1912, it has been becoming the focus that university pays attention to. There is an important transition from analytical paradigm to field paradigm in the method of research on university innovation and management which adopts a wholly thought on innovation system. In recent years, the field theory research has become the hot issue in the study of management and innovation and have made some valuable academic achievement. As one of the innovative achievement, the knowledge with the accumulation, continuity, diffusion and non-exclusive usage shows it has the properties of flowing in essence. Its mobility has made innovative achievements get inheritance, transmission, sharing, social applications and create value for the whole society. The new classical economics think that the innovative achievements knowledge is public goods. so it may be for dissemination and transfer without cost and themselves does not affect the transfer process, the discussion about Knowledge field begins with the fields of philosophy. Miehael Polany at first put forward the concept "the general field" from the angle of the philosophical cognition, Hildrun Kretschmer pointed out: .Near the end of the twentieth Century a series of holism nature theory had been established among which some theory also implied the concept of field Pribram KH thought "as long as there is the far field effect to be illustrated, there is the concept of field to be used "Ikujiro Nonaka proposed the knowledge creation process (SECI) model and the corresponding the creating field, the dialogue field, the system field and the practice field. Chinese scholars Lixi Min, ZhangLi and Liuxi song have researched the concept, establishment, measurement and operation of knowledge field. Based on these studies this paper will build three-dimensional innovation field space of university and research innovative energy flowing within the field space in order to provide some beneficial ideas and method for university innovation activities.

2 Constitution of University Innovation Field Space

Innovative energy is an intelligentized spiritual energy released by innovation subject in innovation activities.it is embedded in innovation subject which in the levels can be divided into individual, team,

organization until the whole university. No matter what level it is, the subject embedded by innovative energy is called node. Every node both can receive innovative energy and can send innovative energy with the double properties. the node sending innovative energy can be known as the innovation source and the node receiving innovative energy can be seen as innovation recipient. The interaction among lots of innovation nodes in the space in university (including the innovation source, innovation recipient, transmission channels) has formed innovation field of university. Innovative energy in the field flows according to certain rules. The innovation potential energy of each innovation node is constantly changing. Along with the change of the potential energy the nodes are ceaselessly moving. it is through innovative energy flow in the field that complete innovative diffusion and realize innovation to jointly promote the enhancement of innovative stock and innovative flow. University will become more and more strong in the spiral growing of innovation.

Subject system dimension, objective system dimension and environmental system dimension have constituted a 3- dimension space of university innovation field. The interaction and innovative energy flowing among nodes within three-dimensional space have formed the operation system of innovation field. Innovation field is an active field with the source. Each node has the function of innovation source. In innovation field, the closer the distance away from the innovation source, the smaller the resistance of the innovative energy flowing. The node location in the innovation field has described the difficulty easy degree, efficiency and level of innovative energy flowing.

The subject system dimensions of university innovation space: Innovation field subject system refers to the nodes and their attributes. The nodes are innovating subject and the source of innovative energy flowing and form the subject of the innovation field. Innovation field subject system factors include: node cultural characteristics, values, ways of thinking, emotional competence, character trait, trust relations. Its attributes affect innovative energy flow level. The closer the relationship between nodes, the higher the strength of the relationship, the higher the levels of innovative energy flowing. Conversely, the bigger the difference between nodes, the worse the innovation flowing effect. For example, the thinking mode of the two nodes exists a big difference, the innovative recipient cannot understand the expression of innovation source. if the two nodes are more trust, the innovation source will be more active to send innovative energy and the innovation recipient will be more cooperation so the innovative energy transfer effect will be better. the bigger the difference between Node and innovation source node, the farther the distance between its location in space and innovation source node.

Objective system dimensions of university innovation field space: innovation field objective system refers to the objects of the innovation and their attributes. innovation objects include intellectual innovation, technology innovation, management innovation, system innovation, culture innovation. Innovation attributes include innovation tacit (i.e., explicit and implicit), Systematicity, complexity, path dependency, innovation fields, innovation levels and other aspects. Innovation attributes affects innovative energy flowing difficulty level. Innovative energy embedded in all sorts of carrier containing nodes inside, Therefore the innovation attribute is also reflected in the nodes. The higher and the more complicated the innovative recessive degree of node, the bigger the difference of the innovation field and level between two nodes, the more difficult the innovative energy flowing will be, the farther the distance between the corresponding nodes. On the contrary the closer the location of the nodes in the innovation field.

The environment system dimensions of university innovation field space: innovation field environment system refers to the environment factors of innovation energy flowing among innovation subjects which can be divided into the soft environment and hard environment, including development level, physical geographical, organization boundary, information infrastructure, school ethos, system characteristics, Innovation atmosphere and mechanism, technical level, communication standard and so on. These aspects constitute the development distance, organization distance, system distance, physical distance, communication distance and the technology gap distance of the nodes and form the present location gap of the nodes in the field space. The environmental factors influence the efficiency of innovative energy flowing. The smaller and the closer the distance among the nodes, the more conducive the environment to innovative energy flow, the smaller the resistance of innovative energy flowing, the higher the efficiency of the innovative energy flowing, the spatial location of the nodes is closer each other. And vice versa.

University innovation field is shown in figure 1. Its space vector function is as follows:
Figure 1   University Innovation Field Space

$$\vec{k} = k_x(x, y, z)\vec{i} + k_y(x, y, x)\vec{j} + k_z(x, y, z)\vec{k} \tag{1}$$

In which: $\vec{k}$ is the innovation field space vector; k_x、 k_y、 k_z respectively are the projection coordinate of $\vec{k}$ in the x axis(innovation field subject system dimension) ,in the y axis (innovation field object system dimension) and in the z axis (innovation field environment system dimension); $\vec{i}$、 $\vec{j}$、 $\vec{k}$ respectively are the unit vector of the X-axis, Y-axis and Z-axis.

3 Measurement of University Innovation Field

The measurement is to measure the scale of the attribute and feature of innovation field space. From the angle of the vector field, the continuous motion of the node with the innovation potential has made innovation field to be spin field with a source. The innovation field may be depicted by using four parameters such as the flux, the divergence, the ring volume and the curl. From the angle of the scalar field, it can be described by using the characteristic parameters such as the equaled potential surface, the directional derivative and gradient and so on.

3.1 The flux and the divergence of innovation field

3.1.1 Flux

The total flow of creative energy that goes through the curved surface S with the direction along the positive direction at unit time is called as flux. If the total innovation field is composed of two or more innovative field superposition, then the flux of the total innovation field that goes through some curved surface is equal to the algebraic sum of the fluxes that each innovation field passes the curved surface. When the close curved surface S is a particular area, one can consider the inflow and outflow of innovative energy within the area. The positive side means from the inside to outside. When the innovative energy from the positive direction passes (outflow)the area, then the flow is positive; When the innovative energy from the negative direction passes (inflow)the area, the flow is negative. Flux is algebra summation of the positive flow which goes through the area from the positive direction and the negative flow which goes through the area from the negative direction. When $\varphi > 0$,it shows that outflows is greater than inflows, this time the area contains the source of sending innovative energy when $\varphi < 0$, it shows that inflows is greater than outflows, this time the area contains the hole of absorbing innovative energy. It is shown in figure 2.
Figure 2   Innovation Source and Innovation Hole

The area may contain innovation source and innovation hole. As long as the outflow of the innovative energy is greater than the inflows of innovative energy, it can be said that the area contains

the positive innovation source: Conversely, it can be said that the area contains negative innovation source .If $\varphi = 0$, it is not sure whether area contains innovative energy flow or not. It is possible for the innovative energy that absorbs to just offset the innovative energy that sends each other. Flux can describe the regional active degree of innovative energy flow, its concentration ratio that innovative energy tends to focus (it flows from the circumference to the region) and divergent degree that the innovative energy tends to divergence (it flows from the region to all around).The calculation formula of flux φ is as follows:

$$\varphi = \oiint_s \vec{k}d\vec{s} = \iiint_s (\frac{\partial k_x}{\partial x}, \frac{\partial k_y}{\partial y}, \frac{\partial k_z}{\partial z})dxdydz$$

$$\varphi^* = \oiint_s \vec{k}d\vec{s} = \sum_{i=1}^m \oiint_s \vec{k}_i \cdot d\vec{s} = \sum_{i=1}^m \varphi_i$$

(2)

3.1.2 Divergence

According to the positive and negative of the flux that goes through the regional S, one can tell whether there are the positive surface or negative source within the curved surface. Divergence has been introduced to specifically instruct the distribution and the strength of divergent degree of the nodes in the region. That is the net flows which innovative energy flows out of the nodes at unit time. In the neighborhood of node M of the innovation field take any closed curved surface △s (including node M), and take △V standing for the volume △Ω that the closed curved surface contains. If when △Ω has been shrunk to the dot M at any way, the limitation of △φ / △V exists, then it is called the divergence of the innovation field at the node M.The divergence of each node in innovation field constitutes a number field .It is called divergence field. Divergence expresses the changing rate of the flux of some node in the field to the volume. That is the innovative energy flow of the closed curved surface of going through surrounded unit volume which comes from the node It measures the strength of the innovation source and the density of the innovative energy flow. When div>0, it shows that the node is the innovation source; When div<0, it shows the node is innovation hole. The size of the |div| expresses the strength of which the node sends innovative energy or absorbs the innovative energy. Node has double properties of both innovation source and innovation hole which either sends innovative energy or absorbs innovative energy. The formula of divergence div is as follows:

$$div\vec{k} = \lim_{\Delta\Omega \to m} \frac{\Delta\varphi}{\Delta V}$$

$$= \lim_{\Delta\Omega \to m} \frac{\oiint_{\Delta s} \vec{k} \cdot \vec{ds}}{\Delta V} = \frac{\partial k_x}{\partial x} + \frac{\partial k_y}{\partial y} + \frac{\partial k_z}{\partial z}$$

(3)

3.2 Circular rector and rotor of the innovation field

3.2.1 Circular Rector

From the angle of the relationship among the nodes the circular rector is introduced to consider the innovation field with node of mutual connection and interaction, innovative energy flowing circularly among them constitutes a closed loop L. The total innovative energy flow of going through the loop according to the direction that it flows is the circular rector (circulation) of innovation circulation. It measures the degree and level of innovation communication among the nodes. Its amount has something to do with the loop of the node that innovation stream passes and the size of innovation flow within the loop. Its calculation formula is as follows:

$$\Gamma = \oint_l \vec{k} \cdot d\vec{l} = \oint_l k_x dx + k_y dy + k_z dz$$

(4)

3.2.2 Rotor

Divergence has measured the density and intensity of node innovation flow. And judge the node is highly innovative or lowly innovative. But it has not measured the biggest innovative flow and the direction of the innovation flow. So the concept of rotor is introduced. In node M of the innovation field, the vector whose direction is the direction of the biggest innovative energy flow at node M, whose modulus equaling to the maximum innovation at is called the rotor of node M in the innovation field. The projection of rotor at the direction of any vector is equal to the circular rector rotor surface density at the direction. Innovation field rotor has measured the biggest innovative flow of every node in the field and its direction. It has instructed the relationship between each node and innovative energy flow.

Calculation formula of rotor rot is as follows:

$$rot\vec{k} = \begin{vmatrix} \vec{i} & \vec{j} & \vec{k} \\ \dfrac{\partial}{\partial x} & \dfrac{\partial}{\partial y} & \dfrac{\partial}{\partial z} \\ k_x & k_y & k_z \end{vmatrix} \tag{5}$$

$$= (k_{zy} - k_{yz})\vec{i} + (k_{xz} - k_{zx})\vec{j} + (k_{yx} - k_{xy})\vec{k}$$

3.3 Directional derivative and gradient of innovation field

Consider the innovation field for the scalar field, we can have described it by using equipotential surface, directional derivative and gradient.

3.3.1 Equipotential Surface

In the innovation field, when node is closer to the innovation source, the flow of innovative energy is more easily; when it is far away the innovation source, the flow of innovative energy is difficult. In order to describe the difficult or easy degree of innovative energy flow in the innovation field we introduce the concept of equipotential surface. It is a curved surface composed of the dots put together that the difficult or easy degree of innovative energy flow is equal. In two-dimensional innovation field, it is a series of concentric circular surface with the source of innovation as the center. In the three-dimensional field, it is a series of concentric spheres with the source of innovation as the center.

3.3.2 Directional Derivative

Directional derivative describes the change of innovation flow along arbitrary direction. in the neighborhood of each node within innovation field which embodies the flowing velocity of innovative energy in any direction. When directional derivative is greater than zero, it expresses that innovation flow along the direction of the L at the node is increased; whereas it is reduced. Through the directional derivative the direction of the fastest growth, the fastest decline and the zero growth of innovative energy flow can be found. Directional derivative is the changing rate of innovative energy flow along the direction of the L at node M0 to the distance. If M is a moving point along the direction of the L at nearby fixed point M0; ρ is the distance between M and M0; then the formula of directional derivative for calculation is as follows:

$$\frac{\partial k}{\partial l_{m_o}} = \lim_{m \to m_0} \frac{k(m) - k(m_0)}{\rho} \tag{6}$$

$$= \frac{\partial k}{\partial x}\cos\alpha + \frac{\partial k}{\partial y}\cos\beta + \frac{\partial k}{\partial z}\cos\gamma$$

3.3.3 Gradient

Directional derivative can describe the changing rate of innovative flow along particular direction at some node of innovation field. Gradient describe along which direction the changing rate of innovative flow is the biggest rate and how much is the changing rate. The gradient at the node is a vector, whose direction is the direction of maximum changing rate of innovative flow, whose modulus equals to the value. of the maximum changing rate of innovative flow at the node. Gradient is perpendicular to the equipotential surface that goes through the node, always pointing to the direction with the increase of innovative energy flow. It measures the change rate of innovation flow and the flowing speed of innovative energy. Its direction is the fastest one of innovation flowing and its size indirectly depicts the flowing speed of innovative energy. From the angle of change and speed of innovation flow in different direction of node individual direction derivative and gradient consider innovation field. The calculating formula of gradient is as follows:

$$grad\,k = \frac{\partial k}{\partial x}\vec{i} + \frac{\partial k}{\partial y}\vec{j} + \frac{\partial k}{\partial z}\vec{k} \tag{7}$$

4 Operation System of University Innovation Field

The entity element of innovation field is a node. Each node is a field source. All the nodes connected with each other and their common function constitute a field space, in which Innovative energy flows and node is impacted by the innovation field force. With the flow of the innovative energy,

the change of environment and the change of position of the nodes in the field; with the interaction and mutual influence among nodes, the innovative potential energy has been upgraded and innovation stock is increasing as a result.

4.1 Innovation potential difference

The potential difference of innovation node exists. As university innovation subject, as for as the individual is concerned, because of the difference of individual talent, qualification, quality, experience, education background, effort degree and specialization division and so on, their innovation ability are different as a result, which reflect the difference of the individual innovative potential energy. As university of the innovation subject, because of the difference of its member ability level, degree of cooperation tacit, university culture, convention, member's ability structure and degree of integrated innovation caused by complementary advantages, these different factors resulting in the resultant force difference formed by the interactions among members under environment background, which embodies the difference of the university innovative potential energy. The distribution of innovation in time and space is not balance. so the innovation potential energy between the innovative nodes is different. There are relative high potential energy nodes and the low potential energy nodes in the innovation field. There exists the potential energy difference   between nodes. The potential difference between innovation nodes brings about innovative energy flow. Innovative energy flows from high potential nodes to low potential energy nodes.

4.2 Force and intensity of university innovation field

Any one node is impacted by the force of innovation field. It comes from the interactions among the nodes in the innovation field. The Coulomb's law is the special form of gravitation in the electrostatic field. It can be used in the innovation field. In which the size of interaction force between two nodes is proportional to the product of the capacity Q (potential energy) of innovation source energy and the innovation potential difference Q-q (potential difference) of two nodes; and inversely proportional to the square of the distance r between two nodes; the direction of interaction force is along connection of the two nodes. The higher the innovative energy of the innovation source, the greater the driving force of the innovative flow. Another factor influencing on the size of the force is the innovative potential gap between the innovation source and the innovation energy receiver. If the innovative potential energy gap between two nodes is too little or close to the same, then that would not have occurred the innovative energy flow. The bigger the gap, the higher the innovative flowing efficiency, the bigger the work done the field force. But it is necessary to point out that the innovative potential energy gap between nodes cannot be too big, if it exceeds a certain limit, because of the constrains of the receiver's understanding and accepting ability which may lead to the fact that the flow of innovative energy is invalid. So in the innovation field, innovative potential gap only in a certain range can effective innovative energy flow be maintained. K expresses the critical point of the innovative potential energy gap between the innovation source and innovation energy recipient which can guarantee the effective innovation energy flow. Node distance reflects the difficulty easy degree of the innovative flowing, which reflects comprehensively the various factors influencing on the innovative energy flow. the smaller the distance, the smaller the resistance of all aspects, the stronger the power: instead, the greater the distance, the weaker the power. K is a flowing coefficient, influenced by the innovative flowing will, the innovative consciousness, the sending ability of the innovation source; the receiving will, the innovative absorptive capacity of the innovative energy recipient and the flowing channels and so on. The intensity can be calculated through the force of the innovation field. The formulas of force F and intensity E of innovation field is as follows:

$$\vec{F} = k \frac{Q(Q-q)}{4\pi r^3}\vec{r}, 0 \le (Q-q) \le k$$

$$\vec{E} = \frac{\vec{F}}{Q-q} = k \frac{Q}{4\pi r^3}\vec{r}$$

(8)

Field superposition principle: when there are more than two innovation source nodes in the field space, the total force on a receiver is equal to the vector summation of the force the other innovation source nodes exist alone and exert on the node. The field intensity of the N nodes at some point of the innovation field space is equal to the vector summation of the field intensity of the point with each node existing alone. The superposed field intensity formula is as follows:

$$\vec{E}^* = \sum_{i=1}^{n} \vec{E}_i = \sum_{i=1}^{n} k \frac{Q_i}{4\pi r^3}\vec{r}$$

(9)

4.3 Innovative energy flowing in innovation field

Innovation field force makes innovative energy flow from the higher potential node to the lower potential node. Node not only receives the innovative energy coming from different nodes in different direction but also sends innovative energy for the different nodes in different direction. With the constantly absorption of innovative energy from other innovation source node and with the realization of innovation in the circulation, feedback and synergistic of innovation energy, which makes the innovation potential energy of the nodes constantly changing and growth and which makes field intensity of the nodes continuously increase as a result the innovation field effect is more and more strong. Due to the difference of innovative contents, categories, object and direction and so on, the innovation potential energy exists different levels. The innovation potential energy of two nodes on the different levels exists difference between high and low. The innovative energy of different levels flows between two nodes. So between the same two nodes the role of innovation source and innovation hole is often interchangeable Or a node acts as two roles at the same time .when there exists multiple nodes, innovative energy of innovation source is always the first inflow to the equipotential surface node being nearest away from the node(gradient minimum).the closer the equipotential surface including the node away from the innovation source, the higher the innovative energy flowing efficiency, the better the result. Similarly, the node of receiving innovation energy is also firstly absorbing innovative energy from the node of nearest equipotential surface away from it. After the node has absorbed the innovative energy from innovation source node, the node will also become another source node for the innovation and has sent this innovative energy for other nodes. As shown in figure l, relative to the node C, node B being on the closer equipotential surface away from node A, so node B the first get innovative energy from A node. After mastering this innovative energy, B node begin to send the energy to C node, while the innovation energy flows from A and B node to C node simultaneously**.**

4.4 Field hole

A field hole is similar to the social network structure hole. In the field innovation, there is not always direct innovative energy flowing between any two nodes. When the distance between the nodes is too far, the resistance is too large, the force of innovation field is close to zero. Thus there is not direct contact between two nodes, the innovative energy flowing is invalid. But innovative energy of innovation source through a bridge indirect can be transmitted to innovative energy recipient, this bridge location is known as a field hole, which has connected two nodes with no direct link. As shown in figure 1, the distance between A node and node D is too far, they do not happen direct connection with no innovative energy flowing, but node C has contact with node A and D, it is in a location of the bridge. The nodes C obtained innovative energy at node A and then transfer to node D. The node occupying a field hole has information advantages and control advantage, simultaneously occupying nodes can get the non-repetitive information from multiple aspects with asymmetric information advantage.

5 Movement and Evolution of the Innovation Field

5.1 Evolution of node potential energy and field intensity

With the mutual connection and interaction between innovation subject, the flowing and collision of innovative energy between them form the space with field effect. In the process of innovation flow, the nodes get innovative energy and realization of innovation unceasingly so that its innovative potential energy upgrades, the intensity of innovation field increases and field effect enlarges. The enhancement of innovative potential energy for node also make the gap of the innovative potential energy between nodes become smaller, the force of field decreases. When the innovative potential gap between the nodes is close to equality (each node has mastered needed innovation energy), innovative energy will no longer instruction type flow, more is through the collaborative and the independent to realize innovation so as to enhance the innovative potential energy of the nodes and produce the new potential gap. At the higher level the flowing of innovation energy between nodes has been realized as a result. At the same time, the recipient of innovative energy has been transformed into innovation source node which can sent out innovative energy. As a matter of fact, there are constant nodes which exits or joins the innovation field. The entry of new innovation source node leads to enhancement of the field intensity; the exit of innovation source node and Innovation transfer node results in imperfect of the field intensity, which has been always changing.

5.2 Evolution of node location and innovation field measurement

The mutual influence and synergy between the nodes makes its behavior, psychology, thinking patterns and values change constantly; the close to each other and mutual understanding between nodes

shorter their cultural differences, thinking difference, systematic distance, psychological distance and so on. In the innovative energy flowing of the long time, the communication standard, metaphor and common language between the nodes have been formed in order to improve the innovative energy flowing efficiency, reduce innovation energy flowing obstacles and make the location of two nodes in the three dimensional field space be near constantly. That node is close to a node in every respect at the same time may make the difference between the nodes and another node widen, make the distance between the nodes pull away, the force that each node has exerted on the node has formed a joint effort, the node in the role of the force constantly changing his location. Within Innovation field among nodes through the exchange, communication, mutual influence, resonance, synergistic effect makes the relative position of nodes change. the absolute location of nodes in the innovation field. Also be changed constantly. Its geographic location, development level, organization, innovative potential energy is ceaselessly changing. This makes node move to the closer equipotential surface away from the innovation source or makes it move to the further equipotential surface away from the innovation source. These make nodes motion in the innovation field, make its location constantly change, make inside innovation field continuously for dynamic change. Innovation field constantly goes through field intensity change and node motion dynamic evolution. The Measurement parameters of innovation field such as flux, circular rector, rotor, directional derivative, gradient, divergence and so on has also been changed.

6 Conclusion

Innovation is the soul and motive force of university growth. innovative energy is an intelligent spirit energy released by innovation subjects in the innovative activities. Innovative energy is embedded within the innovation subject, who embedded by the innovative energy is called nodes. The nodes can both release the innovative energy and absorb innovative energy. The mutual connection, cooperation, coordination between two nodes constitutes the innovative energy flowing chain. The multiple nodes and multiple chain form innovative energy flowing network. With network continuous extension and expansion, with node constant collection and concentration, this makes innovative energy flow depth and breadth expand constantly, the flow and stock of innovation increase and the field effect form. The university innovation field will be constituted as a result. The situation structure of innovative energy flowing among the nodes experiences the movement of the chain structure→ network structure→ spatial structure, along with the evolution of innovation chain→ innovation network→ innovation field. The innovative energy flow effect finally changes from the mode of network to the mode of the field. On the bases of constituting 3 d innovation field space with subject system dimension, object system and environment system dimensions this paper has conducted a comprehensive description on university innovation field space by utilizing Flux and Divergence, Circular Rector and Rotor, Directional derivative and Gradient and field Force and field Intensity. Moreover, it has probed into the operation mechanism of university innovation field space and revealed the evolutionary law of node potential energy and field intensity, node location and innovation field measurement of university innovation field space. The research on innovation field will provide a new method for the innovation management of university and help innovative university from behavior and psychology guide and promote the active and effective innovative energy flowing among the nodes and the sharing and the realization of innovation. As for the self-organization evolvement rules of university innovation field space will be studied further.

Study on the Clustering Development of Provincial Cultural Creative Industry of Hubei Province

Huang Tianwei, Fan Fan, Li Xiaoqi
School of Management, Wuhan University of Science and Technology, Wuhan, P.R.China, 430081
(E-mail: Lily11010@163.com, VivianF0915@outlook.com, 936151325@qq.com)

Abstract: The paper introduces the spatial autocorrelation analysis method to the quantitative analysis on clustering development of provincial cultural creative industry and make Hubei province as case analysis. With the typical indicators of industrial development situation and calculation of autocorrelation, it analyzes the aggregation degree of the attribute values in spatial unit and adopt different development strategies according to their local conditions which offer useful insights for ultimately achieving the overall coordinated and rapid regional development.
Key words: Clustering development; Cultural creative industry; Spatial autocorrelation; Hubei province

1 Introduction

Spatial autocorrelation analysis initially started in biometric research. In 1950s, Moran put the one-dimensional space concept to the two-dimensional space, based on the biological phenomena, and thus defined the Moran index; Li Yanbo (Li Yanbo, 2011) proposed that the space auto-correlation method is spatial statistical methods reflects certain geographical phenomena or the dependence of an attribute value within the region and neighboring regional units on the property of the same phenomenon.

In order to study the correlation of a particular variable in different spatial positions, we use the space autocorrelation method to analyze the aggregation degree of the attribute values in spatial units. Regional autocorrelation analysis method can be used to analyze the geographical distribution within the regional industrial agglomeration, to estimate the industry clustering and diffusion function of regional units. Therefore, the paper makes functional re-partition based on the result of quantitative analysis.

2 The Principle of Research Methods

2.1 The basic formula

Moran index and the G-coefficient method are the general methods to estimate regional autocorrelation. The author chose Moran index to have a study on the autocorrelation degree within provincial industry clusters. Anselin (Anselin, 1995) Suggested the Moran index formula is

$$Ii = \frac{((Xi - \overline{X})}{S^2} \sum_j Wij(Xj - \overline{X})$$

and Xi is the attribution value of special unit i,

$$\overline{X} = \frac{1}{n} \sum_{i-1}^{n} Xi \, , S^2 = \frac{\sum_{j=1, j \neq i}^{n} Wij(Xj - \overline{X})}{n-1} \, ,$$

Wij is spatial weight matrix, means whether the mutual influence relationship exists between unit i and unit j, which judged by to the adjacent standard.

2.2 The connotation of calculation results

'Related' refers to the growth and decline relationship of two or more variables simultaneously, 'spatial auto-correlation' refers to the correlation of the same variable in different locations. If variable value in a position is high, the variable value in the vicinity is also high, is the positive spatial autocorrelation between two locations; On the contrary, a negative spatial autocorrelation. According to different values of Ii, local spatial auto-correlation is divided into four types as shown in table 1.

Table 1   Calculation Results of Values of Ii

Type	Ii Value	Connotation	Spatial Meaning
HH	Ii>0	Positive spatial autocorrelation	Attribution value in area i is higher than regional average level
LL	Ii>0	Positive spatial autocorrelation	Attribution value in area i is lower than regional average level
HL	Ii>0	Negative spatial autocorrelation	Attribution value in area i is higher than regional average level
LH	Ii>0	Negative spatial autocorrelation	Attribution value in area i is lower than regional average level

3 The Spatial Autocorrelation Estimation of Hubei Provincial Cultural Creative Industrial Clustering

3.1 Case analysis of Hubei province

This paper selects 17 cities in Hubei Province as the research objects, takes the output of cultural creative industrial value as the evaluation index. Firstly, defining spatial weight matrix W based on the adjacency standard. If two cities are adjacent, it is 1 for their relationship; if two cities are separated in the map, it is 0 for their relationship. Secondly, taking 17 cities' total cultural creative industrial output in 2016 as property values, to calculate the difference between each city's industrial output and the provincial average output($\triangle$IO), each city's spatial autocorrelation I_i is also shown in Table 2. Finally, according to the calculations of I_i values and the classification criteria of spatial autocorrelation, to get Moran index scatter diagram which divided into HH, LL, HL, LH spatial development type.

As it shown in Figure 1, only one cities Wuhan City falls into the HH quadrant, covering 5.88% of the total cities; nine cities Huangshi City, Ezhou City, Jingmen City, Jingzhou City, Enshi City, Suizhou, Qianjiang City, Tianmen and forest areas, fall into the LL quadrant with 52.94 percent; Yichang City,Shiyan City, and Yangyangthree cities, covering 17.65% of the total cities, belong to the HL quadrant; Xiaogan, Huanggang City, Xianning City, Xiantao City, four cities in the LH quadrant, covering 23.53% of the total cities. Based on the basic agglomeration and diffusion principles of regional economic growth pole theory and the identification of industrial clusters, Hubei Province can be divided into four categories of clusters in space functional areas as it shows in figure 2.

Table 2 $\triangle$IO and Spatial Autocorrelation I_i of Each City of Hubei

Area	$\triangle$IO	I_i	Area	$\triangle$IO	I_i
Wu Han	6370.413	1.89672316	Huang Gang	-458.609	-0.17263727
Huang Shi	-58.458	0.021457896	Xian Ning	-538.90	-0.241618255
Shi Yan	7.45346	-0.001185416	En Shi	-1170.143	0.138864310

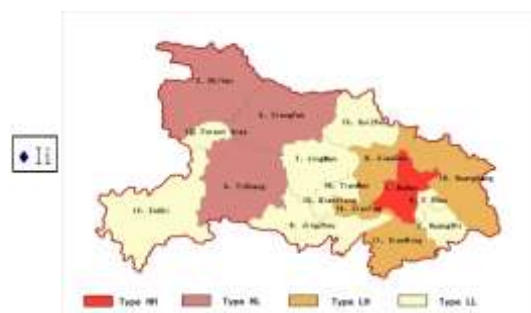
Jing Zhou	-374.212	0.050985124			
Figure 1   Moran Index Scatter Diagram of Hubei Industrial Clustering


Figure 2   Categories of Industrial Cluster in Space Functional Areas in Hubei

3.2 Conclusion of analysis of Hubei province

3.2.1 HH type

Only Wuhan City belongs to this type, which is the diffusion cluster of province's cultural center. With the outstanding cultural development status and strong radiation effect and significant agglomeration benefits to the surrounding cities, Wuhan gives a positive impact to them. It gathers a lot of capital, labor, information, market and other resources, and external diffusion of resources, promotes the concurrent development of the surrounding regional cultural entities.

3.2.2 HL type

In accordance with the growth pole theory, they should be positioned as the 'gathering center'. They need to continue to attract capital, labor, information and other resources from neighbor regions,

which led to low level of industrial development in surrounding areas. They should be classified as the key development areas, to strengthen the focus fostering and obtain the diffusion benefits.

3.2.3 LL type

We can call them 'poverty zone' because of the slow development pace and the backward development situation. However, the local spatial autocorrelation $I_i > 0$, represents these areas and the surrounding areas are correlative, having great potential for the accumulation and spread effectiveness. Therefore, making them as the guiding development areas.

3.2.4 LH type

These 'low-lying' fringe areas in the industrial clusters are formed because of their poor cultural resources resulting in their slow development. Congenital cultural resource endowments are in unfavorable situation. It is difficult to accept the radiation effect from the surrounding developed areas because they lack the internal driving force. They are classified as the moderate development areas.

4 Positioning and Development Strategies for Cultural Creative Clusters

4.1 Instruction to the priority development area of cultural creative clusters

Wuhan City esteems as the priority development area as a provincial capital. It is the only sub-provincial city in the middle of China. Wuhan's cultural creative industrial output value accounted for 15.3% of the provincial total industrial output. With rich cultural resources and intensive development steps, it is proved to be the important competitiveness area of Hubei Province as the leading role in Hubei cultural industry.

Development direction for Wuhan should realize the industrial structure optimization and upgrading by improving industrial growth model, enhancing the participation level in national and global industrial markets, raising the industrial independent innovation capability. We should focus on exhibition industry, cartoon industry and other high-end creative products, introduce more advantageous industrial environmental management systems, strengthen the protection of industrial resources and the environment, play the exemplary role as the leading of industrial clusters.

4.2 Instruction to the key development areas of cultural creative clusters

Shiyan City, Yichang City, and Xiangyang cities belong to the key development areas. Shiyan located in the adjacent area of Hubei, Henan, Shaanxi, Chongqing four provinces, next to the region's largest automobile manufacturing base. Shiyan is known as the "Car City", so it is adaptable to develop creative industry. Yichang, an important industrial city in Yangtze River Economic Belt; Xiangyang is the western fulcrum in Hubei, ranking second in the provincial tourism output.

Although the basis of them is weak relative to the priority development areas, but they have huge development potential. Synergistic effect and spillover effect make a geometric growth of the regional culture creative industry cluster. The advanced methods are using advanced service concepts and management concepts, undertaking the development shift from the priority development areas to accelerate the industrial development pace in accordance with the protection of industrial resources.

4.3 Instruction to the guiding development areas of cultural creative clusters

Nine cities put together to the guiding development areas which concentrated in the southeast region of Hubei Province, covering 52.94% of whole provincial cities, but the total industrial output accounts for only 20.14% of the provincial industrial output. These areas have less development constraints, better overall regional environment; they are back-up entities of the industrial clusters.

Strategies to the guiding development areas are guiding industrial enterprises and institutions cluster in a specific area under uniform layout; Attracting talent, capital, information and other resources, with the introduction of proper cluster development strategies, undertaking the role of co-operators with the key and priority development areas. With the specialization and collaboration development of core enterprises, it will inevitably lead to the extension and expansion of the industry chain because of the characteristics of consumption and transmissibility of the cultural industry.

4.4 Instruction to the moderate development areas of cultural creative clusters

Xiaogan City, Huanggang City, Xianning City, and Xiantao City are the moderate development areas. They scatter around two poles of Hubei province, with only 13.38% of the total provincial industrial revenue. Due to the poor endowment and historical reasons, their cultural industry is lagged behind. According to the proportionality principles of the industrial layout and efficiency principle of resource allocation, these areas should implement differentiation development strategy on the characteristics of regional resources status We can cultivate some cultural enterprises such as music, culture and art, film, animation and traditional handicraft, which will lay the foundation for the

formation and development of regional cultural creative industry chain.

The development methods for the moderate development areas are: firstly, to improve the poor environment for industrial development in these areas to strengthen the construction of industrial infrastructure, fully optimize the environment for industrial development. Secondly, to learn management experience and technologies from the advanced areas, increase productivity and make efforts to improve the professional development level, and ultimately realize the all-round development.

5 Conclusion

The paper suggests that Hubei industry should gradually form the 'point, pole, belt, circle' low-carbon development of spatial pattern. By optimizing the co-ordination and common development among four development areas, we suggest the different strategies of breakthrough and innovative clustering improvement for each city in Hubei.

Meanwhile, the paper uses the quantitative analysis of spatial autocorrelation to analyze the clustering development of provincial cultural creative industry. Therefore, industrial functional clusters adopt different development strategies according to their local conditions; these optimal strategies dynamically evolve with practice and offer useful insights for ultimately achieving the overall coordinated and rapid regional development, which can be used in other cities or countries.

Research on the Factors Influencing the Willingness of College Students' Social Entrepreneurship: An Empirical Study Based on Colleges in Wuhan

Zhang Junhao, Lv Yueqi
School of Politics and Administration, Wuhan University of Technology, Wuhan, P.R.China, 430063
(E-mail: lanbobisheng@163.com)

Abstract: This paper takes the willingness of college students as the research object, constructs the model of social entrepreneurial willingness and the model of non-social entrepreneurial willingness of college students based on the research literature, and finds out the unique influencing factors of social entrepreneurial willingness through comparison. The data of this paper comes from the questionnaire survey of colleges in Wuhan. Through Logistic regression analysis, it will be found that altruistic values, family entrepreneurship atmosphere, entrepreneurship education in colleges have a significant relationship with the social entrepreneurial willingness of college students. Therefore, this paper believes that the cultivation of altruistic values and entrepreneurship education in colleges can promote college students to participate in social entrepreneurship.
Key words: College students; Public interest entrepreneurial willingness; Altruistic values; Entrepreneurship education in colleges

1 Introduction

The Party's 19th CPC National Congress report encourages college graduates to pursue multi-channel employment and entrepreneurship. University students' innovative undertaking can cultivate the innovation consciousness and ability, and alleviate their employment pressure. At the present stage, university students innovative undertaking is mainly divided into social entrepreneurship and non-social entrepreneurship. Colleges encourage and support the college students to participate in entrepreneurial activities, but there is no clear distinction between social entrepreneurship and non-social entrepreneurship, and these two types of entrepreneurship are different. Social entrepreneurship refers to the entrepreneurial activities in which individuals or social organizations pursue innovation, efficiency and social interests under the stimulation of a sense of social mission (G Dees., 2001). Social entrepreneurship pursues the social maximum of profit and the necessary economic benefit, solves the social pain point question, and takes the realization of social benefit degree as the measure standard; While non-social entrepreneurship is oriented to maximize profits, pays attention to the realization of self-needs and self-value, and measures the success or failure of the enterprise by the number of profits. It can be seen that these two kinds of entrepreneurship have the difference in essence. Therefore, it is necessary to study the behavior of social entrepreneurship of college students, which factors make them more willing to choose the social entrepreneurship. This paper attempts to explore the factors that affect the willingness of college students to start the social entrepreneurship through the empirical research, and provides theoretical guidance for colleges to effectively promote college students to participate in the social entrepreneurship.

2 Literature Review and Research Assumptions

2.1 Literature review

College students' social entrepreneurial willingness is the motivation and understanding of individual plan or decision to put into action, and it dominates the attitude and behavior intensity of entrepreneurial practice activities (Conner, 1998; Fan Jinghao, 2018). Gender, entrepreneurship education, family environment, financial support and other factors affect college students' willingness to start the social entrepreneurship (Liu Yuexiu, 2013). Social entrepreneurship is oriented by social demand, which innovates the solving ideas and ways, and shows strong characteristics of sociality, innovation and market orientation (Zhang Rui, 2015). At present, college students' social entrepreneurship is in its start stage, there are some problems, such as lack of value cognition, lack of policy and university support, lack of funds and talents, etc. (Lin Aiju, 2016). In view of this, the scholars suggest that we should create a social public welfare culture atmosphere, build the social entrepreneurship incubator, explore the four-party cooperation mode of "school and government, school and society, school and enterprise, school and youth", so as to promote the sustainable development of social entrepreneurship (Wang Yiming, 2007; Mei Yingying, 2016).

2.2 Research assumptions

2.2.1 Impact of values

Values play a significant role in promoting entrepreneurial activity, such as Protestantism, which spawns entrepreneurial spirit and leads to innovation and entrepreneurship (Weber). Similarly, the participation of college students in social entrepreneurship will also be affected by the values (literature). The values of college students' social entrepreneurship mainly include dedication, social responsibility, social risk awareness and other social personality (Hou Qian, 2017). Therefore, this paper argues that the values can be divided into three types: egoism, altruism and public, among which altruistic values have an impact on college students' willingness to set up social entrepreneurship. Based on this, the author puts forward the hypothesis H1 that the students who have more strong altruistic value, the more inclined to choose social entrepreneurship.

2.2.2 Impact of the family

Distinct occupation of parents has different influence on college students' entrepreneurial action tendency, meanwhile, the relationship between family economic status and college students' entrepreneurial intention is "U", that is, the students with the best and the worst family conditions have the strongest entrepreneurial intention (Krueger, 1993; Chu Chunxing, 2016); However, some scholars think that parents' occupation has little influence on their children's entrepreneurial intention, and that family factors have no great influence on college students' entrepreneurship (Brenner, 1991; Ghazali, 1995; Xie Xijin, 2018). Then whether the family factors affect the social entrepreneurial willingness of college students, this paper puts forward the hypothesis H2 that the students who have richer entrepreneurial atmosphere in family, the more inclined to choose social entrepreneurship.

2.2.3 Impact of entrepreneurship education in colleges and universities

Social entrepreneurial education refers to the education of consciousness, spirit, knowledge, ability and related social entrepreneurial practice activities needed by social entrepreneurship (Tang Yayang, 2011), most scholars study the impact of entrepreneurial education on entrepreneurial intention from entrepreneurial curriculum and innovative talent training mode of colleges and universities (Xiang Hui, 2014). From the perspective of theory and practice, this paper studies whether entrepreneurial education affects the willingness of social entrepreneurship, and puts forward hypothesis H3 that stronger the atmosphere of entrepreneurial education in colleges and universities, the students will be more inclined to participate in the social entrepreneurship.

3 Research Methods and Variable Selection

3.1 Research methods

This paper conducts the questionnaire survey on university students' willingness to start social entrepreneurship in Wuhan. The questionnaire is divided into four parts: basic information, value impact, family environment, and entrepreneurial education in colleges and universities. The project team issued 505 questionnaires in 211 universities such as Wuhan University and Wuhan University of Technology, all of which were withdrawn. Among the respondents, 247 men and 258 women accounted for 48.9% and 51.1% of the total sample respectively.

3.2 Variable selection and description

This paper chooses the social entrepreneurial willingness and non-social entrepreneurial willingness as dependent variables. Social responsibility, voluntary service spirit, innovation spirit, adventure spirit and sense of wealth achievement are all selected as independent variables among the value factors, among which social responsibility and voluntary service spirit are altruistic values, innovation spirit and adventure spirit represent the public value, while the sense of wealth achievement is regarded as the egoistic value; Family factors choose family entrepreneurial atmosphere as independent variables, school entrepreneurial education factors choose policy support, entrepreneurial education, entrepreneurial lectures and entrepreneurial competition as independent variables. The control variables of this paper are gender and discipline. The assignment, meaning and descriptive statistics of relevant variables are shown in Table 1 below:

Table 1 The Assignment, Meaning and Descriptive Statistics of Related Variables

Variable name	Variable meaning and assignment	Mean value	Standard deviation
Social responsibility	Very agreed=0; Comparative agreed=1; Generalization=2; Not quite agreed=3; Very disagreed =4	0.82	1.025

4 Research Model and Analysis

4.1 Research model

This paper carries on the multivariate Logistic regression analysis to the data through SPSS, puts the values, the family, the university entrepreneurial education into the model step by step, and constructs the "model of social entrepreneurial willingness" and "the model of non-social entrepreneurial willingness", then compares the characteristics of social entrepreneurship with the non-social entrepreneurial intention model, highlights the relevant characteristics of college students with social entrepreneurial willingness.

Table 2   The Results of Entrepreneurial Willingness Model of College Students

Variables	The model of college students' willingness to start the social entrepreneurship			The model of college students' willingness to start the non-social entrepreneurship

4.2 Quantitative analysis

4.2.1 Altruistic values are significantly related to social entrepreneurship willingness

The social entrepreneurship emphasizes the promotion of social value and social welfare, and its essential requirements are consistent with altruistic values. The conformity of ideas makes it easier for altruistic college students to recognize the model of social entrepreneurship, and the desire for personal material return and enjoyment is lower, which shows relatively stable and long-term participation power of social entrepreneurship. Public values have neutral value characteristics and have significant relationship with social entrepreneurship and non-social entrepreneurship in general. Public values enhance the sensitivity and ability to capture social problems, and increase the possibility of success in social and non-social entrepreneurship. The influence factors of the social entrepreneurial value are complicated, which involves the egoistic value and the altruistic value, but it is generally controlled by the altruistic value.

4.2.2 Family entrepreneurial atmosphere is significantly related to social entrepreneurship willingness

The study finds that 88.4% of the college students' financial resources are dependent on the financial support of their parents, so their independent personality and behavior choice are greatly affected by the will of the family. Family entrepreneurship atmosphere represents the degree of support on family entrepreneurship support, capital and other social capital. A good family entrepreneurial atmosphere can effectively integrate family resources, interpersonal relationships and other social capital. They even assist and guide their children to participate in entrepreneurial activities. Therefore, family will directly affect the willingness of college students to begin the social entrepreneurship.

4.2.3Entrepreneurial education in college and university is significantly related to social entrepreneurship willingness

In the perfect stage of entrepreneurial policy, the effect of the entrepreneurial willingness of college students is remarkable, but when the entrepreneurial policy of college students is relatively perfect, the flexible space of entrepreneurial policy to affect entrepreneurial willingness is reduced. In the current society, non-social entrepreneurial competition is the mainstream. College students have a high degree of awareness and participation in the "Challenge Cup" and other entrepreneurial competitions, while the social entrepreneurial competition is in its infancy, most of which belong to a part of non-social entrepreneurial events, and lack a better practical platform. Cultivating and triggering the entrepreneurial motivation of college students as a starting point, integrating entrepreneurial policy support, curriculum education and entrepreneurial competition resources, entrepreneurial education provide intellectual support and ability training for college students.

5 Conclusion

5.1 Conclusion of research

Through multiple Logistic regression analysis, it was found that altruistic values, family entrepreneurial atmosphere, entrepreneurial education in colleges and universities had a significant relationship with the social entrepreneurial willingness of college students. Altruistic values make college students have relatively stable motivation to participate in social entrepreneurship, good family entrepreneurial atmosphere can guide their children to participate in entrepreneurial activities, entrepreneurial education provides intellectual support for social entrepreneurship. In view of this, this paper puts forward the following suggestions, hoping to provide certain reference significance for the government and universities to promote the social entrepreneurship of college students.

5.2 Countermeasures and recommendations

5.2.1 Fostering and internalizing altruistic values

The theory of social cognition points out that people's beliefs and motives often strongly dominate and guide people's behavior. The government and society should strongly advocate the spirit of "commonweal" and the culture of "entrepreneurship", and integrate altruistic values into the talent training mechanism. Colleges should pay attention to the cultivation of college students' sense of social responsibility, increase the value education of the first classroom, promote the students to form the concept of social welfare and social responsibility; Strengthening the construction of the second classroom in colleges, taking social practice and volunteer service as the platform, so that college students can deeply understand society and discover social problems, and participate in voluntary service activities through many channels, so as to enhance the sense of charity and social responsibility of college students.

5.2.2 Improving the entrepreneurial education system

Colleges should build and perfect the entrepreneurial education system which combines theory with practice. Set up a high-quality team of social entrepreneurial teachers combining theory and practice, invite

successful alumni to return to school for reports and lectures, and act as outside guidance teachers for practice teams and associations; Vigorously build a diversified practical training platform, link government and social organization resources support on the platform of social entrepreneurial incubator, provide funds, talents, consultation and other services for college students' social entrepreneurship; Encourage college students to participate in the social entrepreneurial competition, and promote the transformation of outstanding entrepreneurial projects into market operation.

Abstract: This articleexamines nascent agricultural enterprise's performance effect ofthe justice perception of equity distributionand entrepreneurial intention, we contextualized the corporation governance theory and operationalized as equity distribution, and adopted 198 nascent small and micro-sized agricultural technological enterprises'datato explore the causality that why the entrepreneurs chose to entry and exit? The results indicate that the justice perception of equity distribution affects entrepreneurial entry and exit behaviors; entrepreneurial entry and exit behaviors impact on performance; and the entrepreneurial entry and exit played mediated role between the justice perception of equity distribution and entrepreneurial performance; the justice perception of equity distribution impacts on performance positively.
Key words: Justice perception; Equity distribution; Entrepreneurial entry and exit; Performance

1 Introduction

Equity distribution signifies the degree of trust for the team members, some empirical evidences show that the harmonious relationship among entrepreneurial team's members will positively impact on nascent entrepreneurial performance (Gemmell, et al, 2012). Certainly, it is emerging as a crucial method in coordinating the equity balance between entrepreneur and other co-founders (Wasserman, 2006). As a reasonable equity distribution of nascent start-ups, it is explored obviously that it will positively motivate the entrepreneurial teams' morale and improve the company's speedy growth, and vice versa, the perception of equity distribution will impact on the entrepreneurial intention: entrepreneurial entry or exit. Entrepreneurial exit is widely regarded as inevitable experience during entrepreneurial process (DeTienne, 2010). In practice, a successful starts-up may specifically get several rounds entrepreneurial entries and exits (DeTienne and Chirico, 2013). Although some existing researches depict that the heterogeneity of founders and co-founders will appeal to more new investors, simultaneously, the operational contradiction amongst original entrepreneurs and new participators also may lead to entrepreneurial exit, and the individual level's ambidexterity is correlated negatively with entrepreneurial entry (Yeganegi S et al, 2018),indeed, the previous researches are prone to discuss identification and exploitation of entrepreneurial opportunity (Shane and Venkataraman, 2000) and how to successfully establish a new business. For small and micro-sized firms, yet, the equity distribution setting has not been paid more attention and not widely recognized, under no circumstance should not we neglect the truth that the equity distribution will play a critical role during new businesses forming and small businesses growing process (Luzzi and Sasson, 2015). This paper will examine the performance effects of equity distribution perception and entrepreneurial entry and exit intentions in nascent small and micro-sized agricultural technological Enterprises.

2 Theoretical Framework and Hypotheses

Obviously, the nascent small and micro-sized agricultural technological enterprises,which compared to the large-sized mature corporations with stable internal control mechanism, own relative flexible corporation governance mechanism (Blatt, 2009) and face high risk of failure challenge when they are entering in an industry (Schjoedt et al, 2013). Indeed, the original founders or family members will dominate the stocks shares that shows highly ownership concentration, it seems to mean that they will bear high proportion entrepreneurial risk (Hall and Woodward, 2010). Nevertheless, the members of nascent entrepreneurial team will undertake more free space to issue new strategy and flexible to implement strategy. On the flip side, both the nascent firms and the mature incumbent firms seek for sustainable development through reasonable governance mechanism: the formers will preserve some

proportion for non-family members or new entry members, who own unique specialties; the latters will properly set a systematic governance mechanism, which consists of "Shareholders'meeting, Board of directors and Board of Supervisors", will help the founders to keep balance of internal relationship. However, the firms' performance is not only constrained by the ownership concentration, they also be influenced by the feeling of new members of the firms, that is referred to the perception of equity distribution. Hence:

Hypothesis 1: The Justice perception of equity distribution will encourage the new members choosing entrepreneurial entry, vice versa, it will choose to exit from the entrepreneurial team.

Actually, entrepreneurial exit is a proactive behavior when the firm will face unbearable difficulties, the entrepreneurial exit aims to take good opportunity to re-enter at a good market situation. The experience and background of entrepreneurial exit will enhance the survival rate of future entrepreneurial process (Albion-S ánchez, 2016). Furthermore, once we discuss the entrepreneurial exit intention or motivation from the individual perspectives of entrepreneurs, we cannot ignore the truth that if the core founder of a nascent firms, who masters the competitive technology, chose to entrepreneurial exit would exert negative influence on the performance (DeTienne and Cardon, 2012). Some scholars will analyses the causing factors through industrial or firm's perspectives(Sarkar et al,2006). Hence:

Hypothesis 2: Entrepreneurial entry will exert positive influence on nascent technological firms'performance; Entrepreneurial exit will negatively impact on Agri-enterprise's performance.

The disequilibrium of market will affect the diffusion of new technology and creative destruction with new methods of production(Hass, 2015).Actually, imbalance is a normal situation that entrepreneur will encounter during the whole entrepreneurial process, nevertheless, there are plenty of literature focused on entrepreneurial entry, and at same time, fewer researches emphasized on entrepreneurial exit, in fact, both of above dual entrepreneurial behaviors are correlated with each other: the high profitable industry will induce thousands of entrepreneurial entries that obviously cause the fierce competition, that means some incumbents will be displaced by nascent firms and forced to entrepreneurial exit. Entrepreneurial exit consists of three strategies: Business is inherited by family member exit or merger and acquire by other companies; bankruptcyliquidation, and the exit types are classified into two dimensions: Firm exit and Founder exit (DeTienne, 2015). Whatever the exit patterns are chose by entrepreneur, the intention will negatively impact on the staff morale, and the entrepreneurial entry will encourage the existing business. Hence:

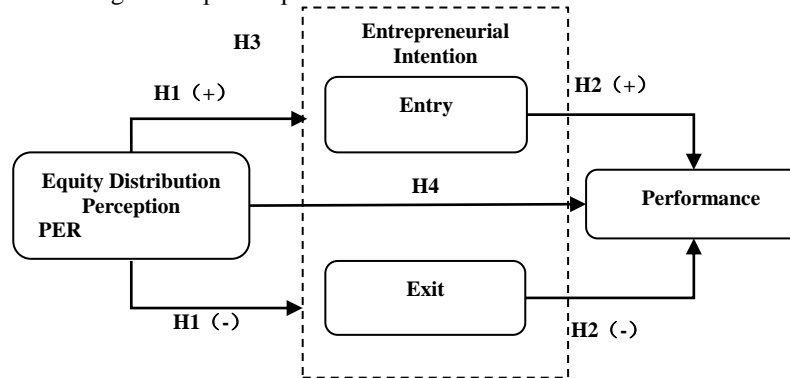
Hypothesis 3: Entrepreneurial entry and exit will mediate this relationship between perception of equity distribution and Agri-enterprise's performance.


Figure 1   The Concept Model

Due to the mobile internet context, some new governance patterns emerge recently, such as crowd-founding, which may cause equity distribution more uncertainty and ambiguity for the entrepreneurial team than traditional governance mechanism. If the member of entrepreneurial team owns high level justice of equity distribution, it will reduce the coordinated cost, avoid agency conflicts (Breugst et al,2015), and also attract more new partners or investors joining in the team, that produce a positive effect on enterprise's performance,otherwise,the distrust will exert a negative effect on firms' valuation as the partners take such perception that injustice for equity distribution. Hence:

Hypothesis 4: The justice perception of equity distribution will positively impact on Agri-enterprises' performance.

3 Data and Methodology

3.1 Sample

As this paper sets the nascent small and micro-sized agricultural firms as research target, the first and foremost thing is to define the nascent firms, that refer to the company which was founded less than 3 years, and then, the agricultural technological firms, which refer to the enterprises that engage in farming, forestry, husbandry and fishing businesses with some innovative technologies. Finally, we defined the small and micro-sized firms as that their annual operation revenue was less than RMB5million yuan according to the definition of Ministry of Industry and Information Technology of the People's Republic of China in 2011. Under the guidance of Economic, Trade and Information Commission of Xiaogan Municipality, our questionnaire investigation was held from July,2015 to September, 2015, we totally sent out 220 questionnaires and recycled valid 198 questionnaires, the valid recovery rate is 90%.

3.2 Measures

Dependent Variable. In entrepreneurial researches field, there is no consensus for measuring entrepreneurial performance as the relative objective financial data is not easy to investigate for business secret, on the other hand, the subjective 5 or 7 scale data cannot signify the firm's real performance. However, under the assistance of local Statistics Bureau, we collected the proactive financial data submitted, which ranges from 2013 to 2014, through the sample Agri-firms, thus, we adopted the ROE (Return on Equity) testified the Agri-firms entrepreneurial performance according the Dupont Analysis Method.

Independent Variables and Mediated Variables. The ownership concentration of a company usually be measured by HHI (Herfindahl-Hirschman index) (Bruton et al, 2010), yet the justice perception of equity distribution as an independent variable is very difficult to be examined by the objective index, as it stands for a psychological cognition for the nascent company, thus we employed five dimensions, which consist of Regulatory Corporate Finance, Position'sOpenness, OwnershipClarity, Reasonable Equity Distribution, and Scientific Organizing, to measure Equity Distribution. Entrepreneurial entry and exit as mediated variables are measured by the intention question items Do you like to accept a new partner joining in your company? Are you plan to exit the company if you feel unfair with the equity distribution?

Controls Variables. In this paper, we also controlled the firms 'size (log employees' number), the form (the firms 'ownership type), and the industry (the various firms from different sectors, farming, fishing etc.)

3.3 Analysis

We employed Multivariate Regression Analysis to analyze how ED (equity distribution) and Entrepreneurial intentions affect Agri-firms' performance. We adopted Two-Stage Least Squares Regression to avoid the endogeneity effect, the first step to take the Entry and Exit as endogenous variables, which they will show in Model 1 and Model2, on the second step, we treated entry and exit as instrumental variables with other independent variables and controls variables to predict performance. Referred to prior scholars' suggestion, we also made a Robustness Test by splitting the sample into two partial samples (Pohlmann, 2002) to testify the entry and exit's effect on Agri-firms' performance respectively.

4 Results

The Table1 shows the factors loading and Cronbach's α value for the five dimensions' Perception of Equity distribution, the values are 0.849,0.850,0.759,0.861,0.903,and the measuring scale's *KMO* and *Bartlett* value is 0.917, all the indicators provide a good reliability level for the scale (*Cronbach's α>0.6;KMO>0.7*); The Factor Loading value of five dimensions are amongst *0.53-0.85*, it presents the scale owns a good convergent validity, and the scale's discriminant validity is acceptable as it is indicated by the *AVE> 0.5*thereof.

To testify our four hypotheses, we employed two steps and six models to analyses the relationship among equity distribution, entrepreneurial entry and exit, Agri-firms' performance in the regression. The Table2 demonstrates that when we take entrepreneurial entry(Entry for short) and entrepreneurial exit (exit for short) as endogenous variables during model1 and model2, the latter one shows that ED (abbreviation for perception of equity distribution) produces positive effect on Entrepreneurial entry($\beta=0.499,p<0.01$) in the first step(the sample number is 198),on the second step and robust test(the sample number is 108),the ED is negatively related with Entrepreneurial exit($\beta=-0.227,p<0.05$),which is

consistent with Hypothesis *1*.The model4'results respectively show positive association between Entrepreneurial entry and performance($\beta=0.157,p<0.05$) in first step and negative association between Exit and performance in second step($\beta=-0.331,p<0.01$），which are in line with Hypothesis *2*.In model 5 and model 6, presumably added the instrumental variable Entry and Exit, the coefficient value β of ED.

Table 1　ED' actors Loading andCronbach's α

Item	Regulatory corporate finance Cronbach's α=0.849					Position's openness Cronbach's α=0.850

Entry (198)				0.157** （0.032）		0.173** （0.037）
Exit (108)				-0.311*** （0.031）		-0.267*** （0.030）
<ED>		-0.227** （0.088）			0.350*** （0.029）	0.301*** （0.028）
R^2	0.046	0.290	0.002	0.025	0.005	0.026
ΔR^2	0.031	0.275	-0.013	0.005	-0.016	0.001
F	3.104**	19.668***	0.131	1.264	0.242	1.035

Note: ∗, ∗∗,∗∗∗ : statistically significant at the10%, 5%, and1% level, respectively

Related with performance respectively decreases into -0.0031 and 0.301, however, the association is positive between Entry and performance($\beta=0.173,p<0.05$),oppositely, Exit is negatively associated with performance($\beta=-0.267, p<0.01$),which is consistent with Hypothesis 3,it means that Entrepreneurial entry and exit play mediated effect between ED and Agri-firms'performance. However, in model6, Hypothesis4 is not verified by the first step, it is supported by the second step($\beta=0.350, p<0.01$; $\beta=-0.301, p<0.01$).

5 Conclusion

Most prior researches pay more attentions to the governance mechanism of mature companies, and neglect the new potential partners 'justice perception for nascent small and micro-seized firms' equity distribution. Thus, this paper extends the equity distribution governance theory to discuss how it will affect on entrepreneurial intentions: entry or exit and then the Agri-firms' performance during a special context such as agricultural industry? This study employed the nascent small and micro-sized agricultural technological companies' sample in Xiaogan Municipality to testify our four hypotheses.

Specifically, our study results show that the justice perception of equity distribution will positively affect the entrepreneurial entry, otherwise, the potential relative stakeholders, which include Venture Capital and Private Entity, will chose to entrepreneurial exit as they emphasize on the equality of equity distribution. Generally speaking, if the original founders over-emphasized their own team's interest will cause the suspiciousness of new partners, that will expel the new participators withdrawing investing

from the current company, hence, the nascent agricultural companies should establish a reasonable governance mechanism that make co-founders feeling justice treatment at the early stage.

Certainly, we consider the endogenous effect of entrepreneurial entry and exit, our findings show that entrepreneurial entry will directly enhance the nascent firm's value, as new investors will input money and other resources after entering; entrepreneurial exit may produce significantly negative effect on firm's performance in short term, yet it couldn't make sure that it will exert a bad influence in a long time, under some circumstance, the entrepreneurial exit will be a promising strategy that beneficial to the nascent firm. On the second step analysis, we operated the entrepreneurial intentions: entry and exit as instrumental variables, the results shew that the entrepreneurial entry and exit respectively produce positive effect and negative effect on the relationship between Equity Distribution and Agri-firms' performance. Obviously, the entrepreneurial entry will encourage the temporal team, that will combine more heterogenetic abilities and resources to improve the firms' value, on the flip side, entrepreneurial behavior will discourage the current staff morale, contemporarily it will decrease the firms 'value.

In the agricultural industry context, the evidence from small and micro-sized firms data shows positive association between the Equity Distribution and firms'performance, it means that the VC or PE will be more sensitive to the governance mechanism at nascent step than mature companies, it also be supported by the findings 'result shown in Table 2 that the Size of firm is negatively related with the performance. Finally, the trust amongst co-founders is crucial to the growth of nascent small and micro-sized technological agricultural firms, it will increase the survival rate of nascent start-ups.

Research on the Relationship among Ethical Leadership, Knowledge Sharing and Organizational Innovation

Xia Xuchen

School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070

(E-mail: 1280447041@qq.com)

Abstract: In today's complex and competitive environment, how knowledge-intensive companies can improve their knowledge management capabilities and organizational innovation levels is an important research topic. Although theoretical researchers have recognized the effect of ethical leadership on knowledge sharing and organizational innovation, empirical studies examining the relationship among the three have not been widely reported.This study found that there is a significant positive correlation between ethical leadership and knowledge sharing by reading a large number of documents and empirical investigations of 159 knowledge-intensive companies; at the same time, it is found that knowledge sharing plays a partial intermediary role between ethical leadership and organizational innovation. Our research enriches the literature on knowledge management and provides useful insights for ethical leadership practices and organizational innovation management practices.

Key words: Ethics leadership; Knowledge sharing; Organizational innovation; Knowledge-intensive enterprise

1 Introduction

1.1 Ethical leadership

The broad-based ethical leadership adopts a normative perspective and focuses on the universal ethical leadership connotation. "Leadership" is the process by which individuals in a leadership role in an organization lead their subordinates to accomplish organizational goals.. "Ethics" is a shared view of "right and wrong" (Brown & Mitchell, 2010). It is a social norm.Integrating the two, "ethical leadership" is the process of demonstration, regulation, and practice of leadership in relation to "right and wrong" standards. The focus of this definition is on "ethics," which ethical norms the leader follows or which moral qualities the leader has. In the narrow sense of ethical leadership, according to the definition of Brown. Ethical leadership is a leadership style that demonstrates normative and agreeable behavior through personal actions and interpersonal relationships, and promotes these behaviors in subordinates through two-way communication, reinforcement, and decision making (Brown, 2005).

1.2 Knowledge sharing

Knowledge sharing is a communication process in which knowledge owners share ideas, issues, and information related to work through communication media and programs. In other words, it refers to the sharing of work-related information, advice, and experience among members of the organization. Nahapiet and Ghoshal pointed out that knowledge sharing among employees can not only promote the use of existing knowledge of organizations, but also promote the creation of new knowledge within the organization. Knowledge sharing is beneficial for companies to acquire knowledge resources and enhance their competitive advantages, and good knowledge sharing has a significant role in promoting corporate performance (BI Wenming, 2017). Huang emphasized that it is also necessary to explore the various factors that affect knowledge sharing in different contexts. From the individual level, they explored the influence of "face concept" and "relationship orientation" on knowledge sharing in Chinese situation.

1.3 Organizational innovation

According to Damampour's study, the most commonly used criterion for classifying organizational innovation is the thoroughness of innovation and the Binary model (Damanpour, 1991). The former divides organizational innovation into gradual innovation and radical innovation. The latter divides organizational innovation into technical innovation and management innovation. Among them, technological innovation can be divided into product innovation and process innovation. This study adopts the binary model definition of technological innovation and management innovation.

2 Research Hypothesis

2.1 Ethical leadership and knowledge sharing

The relevant literature shows that employees within the organization may not be willing or able to

effectively share knowledge. Nahapiet and Ghoshal define social capital in the Social Capital Theory as "the sum of potential or existing resources embedded in the network of relationships owned by individuals or social units". The sum of "Social capital theory" (Nahapiet, J&Ghoshal S, 2000) points out that social capital can provide people with the material support and emotional support they need. Knowledge is essentially a category of information resources, and its access to a large extent depends on the individual's social network. While leadership is an important part of social network relationships, Blau pointed out in the Social Exchange Theory that social exchange is the foundation of interpersonal interaction, with the aim of gaining valuable resources. Knowledge sharing to some extent embodies the interpersonal exchange interaction with knowledge as the object, "ethics" and "morality" are considered to be interchangeable, and ethical leaders are more inclined to empower subordinates and encourage their personal growth, based on social capital theory and social exchange theory, we know that employees will "feedback" their own gains. The organization acts to create an atmosphere of respect for knowledge, resulting in the spread of knowledge.

In summary, ethical leaders can promote knowledge sharing. On the one hand, they can directly inspire individual employees, by encouraging individuals to talk, create, and share. On the other hand, Ethical leadership will influence or control individual employee knowledge sharing behaviors through organizational trust, ethical atmosphere, psychological security, Subordinate relationship (Yang Xia&Li Wen, 2017) and enhance the organizational knowledge sharing atmosphere (Wang Yongyue&Ye Jiajia, 2015). Therefore, we propose the following assumptions:

Hypothesis 1: Ethical leadership has a positive effect on knowledge sharing.

2.2 Knowledge sharing and organizational innovation

Innovation has become an important source of organizational competitive advantage, and the knowledge possessed by the organization is an important resource that affects organizational innovation (Rosenkopf,L&Almeida,P, 2001).Whereas the knowledge possessed by the organization is distributed among different departments and individuals within the organization, through the sharing and exchange of different departments and employees, these knowledge scattered in different departments and individuals can be fully mobilized within the organization. It helps to promote the integration of different kinds of knowledge (Easterby-Smith&Fang les, 2008). Researchers have recognized that the organization's ability to integrate different internal knowledge is a key factor affecting its organizational innovation (Henderson, R&Clark, K, 1992).At the same time, there are studies that show that knowledge sharing within an organization, including informal knowledge sharing and formal knowledge sharing within an organization, can significantly promote technological innovation, while informal knowledge sharing within organizations and between organizations. Knowledge sharing has a positive impact on management innovation.

In summary, organizational innovation is inseparable from knowledge sharing. Knowledge itself provides a resource basis for organizational innovation. Organizational innovation is inseparable from the knowledge enhancement and knowledge innovation brought about by the organization's internal and external knowledge sharing process. So, we propose the following hypothesis

Hypothesis 2: Knowledge sharing has a positive effect on organizational innovation

2.3 The mediating role of knowledge sharing

Studies have shown that there is a significant positive correlation between ethical leadership and employee innovation behavior. Interaction fairness has a complete intermediary role between ethical leadership and employee innovation behavior. Ethical leadership can motivate and induce employees to increase creativity and improve Job satisfaction and create innovative behavior (ZhaoYu&MoShenjiang, 2015). The innovative behavior of employees is an important content and guarantee of organizational innovation. And as Gupta and Singhal have studied, the main asset of innovative organizations is people, not products. Subramaniam and Youndt pointed out that the organization of human capital has an active role in promoting organizational innovation (Subramaniam, M.&Youndt, M, 2005). In other words, only employees who are important human capitals in an organization are the participants and Practitionersof organizational innovation, and employees have the knowledge they possess. It is a key resource for inspiring innovation. Throughout the organization's entire innovation process, employees effectively contribute to organizational innovation by effectively sharing and applying their own knowledge and skills. In order to make the best use of human capital, organizations need a leadership style that is conducive to employees' innovative behavior and organizational innovation atmosphere.

According to the foregoing discussion, we believe that in the process of promoting organizational innovation, ethical leaders can exert their positive effects by effectively influencing the behaviors of participants and Practitioners of organizational innovation, especially such as knowledge sharing

behavior. In other words, the ethical leadership does not directly affect the final organizational innovation results, but it does so through important organizational intermediary such as knowledge sharing. Therefore, we have the following assumptions:

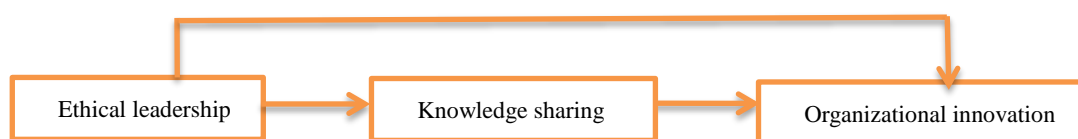
Hypothesis 3: Knowledge sharing mediates ethical leadership and organizational innovation.


Figure 1   Research Model

3 Research Methods
3.1 Research sample and data collection
Ethical leaders may influence different organizational resources and capabilities in different industries. According to the purpose of the study, this paper uses knowledge-intensive companies as research objects. Among them, sample companies mainly include consulting companies, advertising companies, training companies, law firms, and IT companies. We used paper questionnaires and electronic questionnaires to collect data. A total of 324 questionnaires were sent. After screening, we obtained 172 questionnaires. However, due to the deletion of 13 questionnaires that were incomplete, the final questionnaires received 159 copies. The questionnaire recovery rate is 49.0%.

3.2 Measurement of variables
In order to ensure the validity and reliability of the measurement tools, the scales used in this study are all scales that have been used in existing literature at home and abroad, and have been appropriately modified according to the purpose of this study. Ethical leadership.

The Chinese Ethical Leadership Questionnaire (Meng Hui&Song Jiwen, 2014). In view of the special connotation of ethical leadership in the context of China, this paper used MengHui to develop the Chinese moral leadership questionnaire. They used interviews and factor analysis to determine the 24 items and 3 dimensions of the scale: moral quality, respect and tolerance, and moral reward and punishment. A coefficient of the overall questionnaire was 0.949. The coefficients of the moral quality dimension, respect and inclusive dimension, and moral reward and punishment dimension were 0.923, 0.918, and 0.867, respectively. CELQ can be considered as having high reliability.

Knowledge sharing. This article uses a scale with four items used by Cabrera to measure the behavior of employees sharing information, advice, and experience. The fourth item is reverse-encoded. (Cabrera, A&Collins, W. C, 2006). Based on this, we have made appropriate changes to the scale. We changed the subject "I" of the original scale into a "company employee" to measure the overall situation of the organization. The internal consistency reliability coefficient of this scale is *Cronbach's a = 0.67.* which Reflecting the fit of the factor model is acceptable.

Organizational innovation. Jimenez-Jimenez and Sanz-Valle (Jimenez-Jimenez, D&Sanz-Valle, R, 2008) used a scale with nine items to measure three aspects of organizational innovation: product innovation, process innovation, and management innovation. The internal consistency reliability coefficient of this scale is *Cronbach's a = 0.91.* which Reflecting the fit of the factor model is acceptable.

4 The Results of the Study
4.1 Correlation analysis
The mean, standard deviation, and correlation coefficients of all variables are shown in Table 1. From the correlation coefficient matrix table, we can see that there is a significant correlation between ethical leadership, knowledge sharing, and organizational innovation. Moreover, there is a positive correlation between ethical leadership and knowledge sharing, knowledge sharing, and organizational innovation.

Table 1   Correlation Coefficient Matrix

variable	Mean	S.D	1	2	3	4	5
Age of company	19.55	26.78	1				
Company Size	2.82	0.98	0.389***	1			
Ethical leadership	56.66	11.42	0.153	0.044	1		
Knowledge sharing	20.72	4.20	0.058	-0.142	0.519***	1	
Organizational innovation	41.78	12.05	0.063	-0.055	0.376***	0.409***	1

Note: 1.*** indicates P<0.01, ** indicates P<0.05, * indicates P<0.1

4.2 Hypothesis testing

For the hypothesis test, this study used statistical analysis software SPSS11.5 to conduct multiple regression analysis.

4.21 Regression analysis of the relationship between ethic leadership and knowledge sharing

Table 2   Regression Analysis

Variable	Knowledge sharing		Organizational innovation	
	Model 1 Regression coefficients	Model 2 Regression coefficients	Model 3 Regression coefficients	Model 4 Regression coefficients
Control variable				
Age of company	0.102	0.051	0.032	-0.025
Company Size	-0.196*	-0.188**	0.057	0.112
Ethical leadership		0.598***		
Knowledge sharing				0.317***
R^2	0.038	0.257	0.029	0.107
Adjusted R^2	0.019	0.292	-0.022	0.090
ΔF	1.921	32.694***	0.178	12.898***

Note: All regression coefficients have been standardized

This study assumes that ethical leadership has a positive effect on knowledge sharing. Model 1 of Table 2 examines the effect of control variables on knowledge sharing. Model 2 shows that there is a significant correlation between ethical leadership and knowledge sharing after controlling the age of the company and the size of the company. The standardized regression coefficient is *Beta=0.598, p<0.01*. This means that ethical leaders who focus on employee development have a positive impact on knowledge sharing. Hypothesis 1 of this study was supported.

4.22 Regression analysis of the relationship between knowledge sharing and organizational innovation

In this study, we assume that knowledge sharing has a positive effect on organizational innovation. Models 3 and 4 of Table 2 show the test results of this hypothesis. In Model 3, we only examined the impact of company age and company size on organizational innovation. Model 4 shows that there are significant correlations between knowledge sharing and organizational innovation after controlling for the age and scale of the company. The standardized regression coefficient is *Beta=0.317, p<0.01*. Hypothesis 2 of this study has been supported. This shows that within the organization, different employees actively share their knowledge, experience and experience can bring about a higher level of organizational innovation.

4.23 Analysis of the mediating role of knowledge sharing

The second important purpose of this study is to test the mediating role of knowledge sharing between ethical leadership and organizational innovation. According to the research(Baron R. M &Kenny D. A, 1986),to verify the intermediary role played by knowledge sharing, four conditions need to be met.: (1) The relationship between ethical leadership and knowledge sharing is obvious; (2) The relationship between knowledge sharing and organizational innovation is significant; (3) The correlation between ethical leadership and organizational innovation is significant; (4) After the variable of knowledge sharing is added to the theoretical model, the ethical model The relationship between leadership and organizational innovation will change. If the original correlation does not exist, it indicates that knowledge sharing plays a complete mediating role; if the original relationship weakens, it indicates that knowledge sharing plays a partial intermediary role.

In order to test the mediating role of knowledge sharing, we tested the regression coefficients in turn according to the above criteria. The results are shown in Table 3.

Table 3   The Mediating Role of Testing Knowledge Sharing

Variable	Organizational innovation		
	Model 1 Regression coefficients	Model 2 Regression coefficients	Model 3 Regression coefficients
Control variable			
Age of company	0.026	-0.023	-0.035
Company Size	0.051	0.047	0.092
Ethical leadership		0.356***	0.244**
Knowledge sharing			0.236*
R^2	0.028	0.132	0.151
Adjusted R^2	-0.023	0.094	0.123
ΔF	0.171	12.884***	3.873*

In Table 3, we use Model 1, Model 2 and Model 3 to test the mediating role of knowledge sharing between ethical leadership and organizational innovation. Model *2* shows that after controlling the company's age and company size, there is a significant correlation between ethical leadership and organizational innovation *(p<0.01)*. Model 3 is a full model. After adding the variable of knowledge sharing, the regression coefficient of the ethical leader became 0.244, and the correlation with organizational innovation was reduced, and its significance became *0.01<p<0.05*. At the same time, knowledge sharing the regression coefficient for this variable is 0.236, and it is statistically related to organizational innovation as a general correlation *(0.05<p<0.1)*. This means that after the variable of knowledge sharing was added, the influence of ethical leadership on organizational innovation was reduced, and knowledge sharing partially replaced the effect of ethical leadership on organizational innovation. Therefore, we believe that knowledge sharing plays a partial intermediary role between ethical leadership and organizational innovation.

5 Conclusion

This article takes a knowledge-intensive enterprise as the research object and discusses the relationship among ethical leadership, knowledge sharing, and organizational innovation. We have mainly done two tasks: (1) examining the influence of ethical leadership on knowledge sharing; (2) and testing the mediating role of knowledge sharing in the relationship between ethical leadership and organizational innovation. The main conclusions are as follows: (1) The ethical leader has a positive role in promoting the sharing of knowledge among employees. Since many researchers have investigated the impact of ethical leadership on employee innovation behavior, following this logic, hypothesis 1 was supported *(p<0.01)* by theoretical analysis and empirical tests. This shows that the organization managers can use ethical leadership to enhance the relationship and communication between managers and employees, and promote the sharing of knowledge among employees. (2) Knowledge sharing can promote organizational innovation (hypothesis 2). This study hypothesis was also supported by empirical results *(p<0.01)*. This shows that knowledge sharing can promote organizational innovation by facilitating the flow of knowledge within the company and accelerating the integration of knowledge within the organization. (3) Knowledge sharing plays a partial intermediary role between ethical leadership and organizational innovation (hypothesis 3).

There are also deficiencies in this article. This study does not control the nature of the ownership of the company. Considering that foreign companies, state-owned enterprises, and private enterprises may have different incentives for innovation, future research needs to control this variable. In addition, you can also continue to study the relationship between the level of ethical leadership and employees' knowledge sharing. Future research should focus on these issues.

A Study on Burden-reduction Strategies in Chongqing Small and Medium-sized Enterprises

Fu Meiju, Cheng Yanxia
School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: 574972976@qq.com, chengyanxia221@126.com)

Abstract: As the number of SMEs in Chongqing is growing, they have become the key to the smooth running and development of Chongqing economy. It also plays an important role in absorbing employment. However, for small and medium-sized entrepreneurs whose own capital is relatively scarce, they feel too much pressure by these burdens like high taxes and financing cost etc. Government adopts a series of burden-reduction policies of benefiting enterprises to reverse the situation and help SMEs to resolve difficulties. Through reading all kinds of literature to understand the existing countermeasures and implementation, through the issuance of questionnaires to a number of SMEs, a practical understanding of the source of the burden of SMEs, and a profound understanding of the difficulties of the managers of SMEs. This article mainly studies the reasons of heavy burdens in Chongqing SMEs, and the financing channel of entrepreneurs to find effective ways to get them out of trouble.
Key words: SMEs; Burden-reduction; Strategies; Heavy burden; Financing difficulties

1 Introduction

At present, SMEs trapped in the mire of weak capital, lack of resources, lack of ability, and many taxes and difficulties. The government has the right and obligation to support SMEs. "The reduction of negative" action is imperative. In addition, with the slowdown of economic growth, the performance of enterprises is declining, and the whole economic environment is at a low pressure. Therefore, the research on reducing the burden of SMEs in Chongqing is in line with the current economic development situation and plays a vital role in the future economic development of Chongqing.

Domestic scholars have done a lot of research on the issue of "burden reduction". Zhang Long (Zhang Long, 2012) believes that the macro negative tax collected by China don't compared well with the developed countries, but the main problem is all kinds of miscellaneous taxes. In addition to the positive tax, the tax obligation of the enterprise is also required to deal with the administrative charges on the heels of the governments at all levels. Gen Lin (Gen Lin, 2011) believe that the burden of SMEs is mainly because of the difficulty of financing. Aiming at the problem of burden reduction for SMEs, domestic scholars have worked hard and put forward some measures to solve this problem. Wang Lijuan said (Wang Lijuan, 2001), rational use of tax planning methods, making full use of various preferential tax policies, and emphasizing the establishment of long-term mechanism are important measures to reduce burdens. While foreign countries also attach great importance to the reduction of enterprises, Ebiringa(Ebiringa, 2011) said, the governments of Britain and U.S.A have issued a series of "negative" decrees from the thorough examination of government functions, simplification of reports and records and preservation.

2 Development of SMEs in Chongqing

2.1 Concept of SMEs

SMEs are relatively small economic units in terms of personnel size, asset size or scale of operation compared with large enterprises in the industry. This kind of enterprise is made up of a single person or a small number of people, and the number of employees and the turnover are less, so the business is generally managed by the owner and is less interfered by the outside world (Yin Danli, 2009).

2.2 Basic situation of SMEs in Chongqing

In 2017, 127 thousand new SMEs set up in the city. The number of registered households reached 727 thousand at the end of last year, accounting for more than 99% of the total number of enterprises in the city. The added value of 820 billion 470 million yuan, up 10.1%, higher than the GDP growth of 0.8 percentage points, accounting for 42% of the total economy in the city, is an important force in the economic and social development of the city (Chongqing Municipal Bureau of small and medium enterprises, 2018).

Table1   Important Economic Indicators of SMEs in Chongqing in 2016-2017

Index name	2016	2017
1The number of enterprise units (ten thousand)	67.0	72.7
2 Employees (tens of thousands of people)	710	761.2
3 Added value (billion yuan)	7020	8204.7
4 Contribution to GDP growth	42.6%	42%
5Year-on-year growth	11.1%	10.1%

2.3 Characteristics of SMEs in Chongqing

First, the industrial structure has been optimized gradually, but it still needs to be improved compared with the developed areas. SMES are dominated by traditional industries, and the proportion of new and high technology industries is relatively small.Two, the quality of enterprise managers is gradually improving, but competitiveness remains to be improved. Most of the SMES are family enterprises. Many managers lack the theoretical knowledge of management and manage the enterprises only by experience. The decision is not prudent, the strategy is not long, the use of people is not appropriate and the enterprise governance structure is unsuitable, which will lead to the development of the enterprise not long. Finally, it can only choose "close the door". Three, the financing situation is still grim. At present, there are many financing channels, but the total amount of financing from the capital market direct financing and private placement is still weak, and the financing structure needs to be optimized. Besides, the financing of SMES needs to pay high cost, including interest expense and financing cost (Jian Jie,2015).

3 Investigation and Analysis on the Burden of SMEs in Chongqing
3.1 Survey design

In order to understand the source of the burdens of SMEs in Chongqing, the author visited many districts and counties of Beibei, Bishan, Jiangjin, Banan, Fuling and other districts. The project group teacher issues a questionnaire, and successfully recovered 336 questionnaires, by sorting out the questionnaire to get the following data.
Figure 1   The Types of Tax and Fee of 336 SMEs Undertake
Figure 2   The Proportion of 336 SMEs Undertake the Tax and Fee

3.2 Specific analysis of the burden of tax and fee

According to the data, the first major tax types paid by 336 small and medium sized enterprises each year belong to the transfer tax, and 221 enterprises have paid the value-added tax, which accounts for 65.77% of all the research enterprises. There are many SMEs have not reached a large scale, so when they pay the VAT,small scale taxpayers' input tax is not allowed to be deducted and can't enjoy the preferential treatment of the general taxpayer. The second "right-hand man" is income tax, which takes all income as the object of taxation. In addition to various kinds of "taxes", there are various kinds of "fees". Education surcharge, social insurance fee, local education fee, employment fund for the disabled, trade union funds and so on. In addition, it also includes administrative charges levied by many government departments, such as industry and commerce, environmental protection, quality supervision, and so on. Many of these charges are not to be paid by the business profit or not, but must be paid (Wu Wenjia, 2012).

4 Reasons of the Burdens of SMEs in Chongqing

4.1 Government fees

The main types of taxes in China are value-added tax, income tax and business tax, and other taxes and fees are often related to it. In addition, the phenomenon of random charges occurs, but the tax is mandatory, unpaid and fixed, and SMEs can only "eat the Coptis in dumb". Finally, the government has alarge number of charges, and often prone to duplication of fees, cross billing and other phenomena.

4.2 Governance

Some scholars have suggested that the government's corruption has also increased the burden on enterprises to a certain extent. In the form of "eat, drink and play", the expenditure of "eat, drink and play" belongs to all kinds ofnon-taxation burdens, which increase the operating cost and economic burden of the enterprise. The function of our government has not been changed in place, and the revenue and expenditure of the government has not been adequately supervised and restrained by law.

4.3 Policies and benefits

Tax incentives for a certain type of SMES, and indifferent to other enterprises, reflects the unfair market, it is not conducive to the SMES to go hand in hand, and will give local government a huge space for the operation of dark boxes, easily cause political and enterprise undivided, breeding corruption. There is not enough preferential policy will be unfair. The existing structural tax cuts "avoid the heavy lifting" and the effect of reducing the burden of enterprises will give a big discount.

5 Reduction Countermeasures

5.1 Conscientiously implement tax incentives

Small and micro businesses that do not exceed 20 thousand yuan in monthly sales or turnover are temporarily exempt from business tax or value-added tax. To encourage SMEs to give subsidies to the local remaining parts of the enterprise income tax, value-added tax and business tax, and to effectively implement the preferential tax policies to support SMEs (Wang Huilin, 2012).

5.2 Strengthen the management of the fee for enterprise

The establishment of a list of catalogues, the reduction of the amount of the charge items in the government departments, the clearer content and the standard of the charge, the clear and clear payment of the enterprises, which effectively contain all kinds of charges, disorderly fines and disordered apportionment. Charges related to enterprises are open and sunshine, and fees have been reduced greatly.

5.3 Establish a long-term mechanism for reducing the burden ofSMEs

The establishment of long-term effect reduction mechanism will provide a reasonable legal guarantee for the work reduction work, and consolidate the existing achievements of the burden reduction work, and will not make the results of the income reduction in various regions fall down, and can also make up for the defects of the existing system in our country. The state and governments at all levels also realized the importance of establishing a long-term mechanism for reducing burdens. The government of Shanxi has put forward "an effective approach to the construction of long-term mechanism and actively explore the effective way to do a good deal of special governance" (Yi He, 2014). The government of Chongqing suggests "a long-term guarantee mechanism for reducing the burden of enterprises," and so on.

5.4 Work on improving the financing environment

In order to increase the credit of SMEs, it is necessary for the commercial banks to increase the growth rate of loans, increase the increment, simplify the procedure of loan, establish circular loan and so on, and strictly prohibit the "loan deposit" and "deposit and loan link". Establish a docking mechanism for industrial guidance fund projects, so that enterprises can get external support and expand financing channels.

6 Conclusion

Through the analysis of the sources of enterprises' burdens on the spot, this paper puts forward some effective measures for reducing the burden of burden: 1, implementing the preferential tax policy; 2, strengthening the management of the fee for enterprises; 3, establishing a long-term mechanism for reducing the burden of burden; 4, and improving the financing environment. The four above are guided by the government and hope that these jobs will be improved qualitatively during the 13th Five-Year. The government is the main force in reducing the burden of enterprises, and the strength of enterprises should not be underestimated. This article is only limited to the government's point of view and puts forward the countermeasures. In the future, we still need to find the important means of reducing the burden from the enterprise, and combine the government policy with the enterprise action effectively and play a beautiful "combination boxing".

Impact of Strategic Planning and Management on Performance of Small and Medium-sized Enterprises in Laos

Phoungphaynome Inthavong, Liu Guoxin
School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: Inthavongphoung77@yahoo.com, syliuguox@126.com)

Abstract: Small and medium-sized enterprises (SMEs) play a vital role in the economic development of Laos. However, SMEs in Laos are relatively small and lack competitiveness. The inflow of foreign direct investment (FDI) and trade liberalization in Laos brought both opportunities and challenges for SMEs in Laos. Over the last two decades, SMEs have gained wide recognition as a major source of income generation, poverty alleviation, employment and regional economic development in Laos People's emocratic epublic (PDR). However, issues relating to SMEs and assessment of SMEs performance are not well understood due to lack of studies. The factors such as locus of control need for achievement, risk-taking propensity, strategy making, environmental uncertainty, and infrastructure have been viewed as critical factors for the performance of SMEs. The objective of this study is also to evaluate the aforementioned factors in assessing the performance of SMEs in Vientiane Province in Laos. Following the survey research design and convenient sampling method, data for the study was collected from 100 SMEs in Vientiane Province using structured questionnaires. The data were analyzed using Pearson Correlation and hierarchical regression to identify the relationship between study variables and impact on the performance of SMEs. The findings indicate that the owners have a high level of internal locus of control and need for achievement; owners willing to take a moderately high-level risk and significant differences between male and female owners on the locus of control, need for achievement and risk taking propensity.
Key words: SME; Performance; Factors; Laos

1 Introduction

Laos joined the Association of Southeast Nations (ASEAN) in 1997 and Asian Free Trade Area (AFTA) in 1998. As part of its commitment under the AFTA agreement, Laos had to reduce the tariff rates to 0 to 5 percent in 2008. Reducing tariff rates would increase imports and have a negative impact on the domestic economy. Moreover, increasing FDI is expected to play an important role in increasing SMEs productivity. On the other hand, FDIs may reduce the number of domestic investments, especially those of SMEs. Most SMEs in Lao face challenges and constraints, such as lack of financial support and inadequately skilled labor, and low level of competitiveness.

It is widely accepted that SMEs play a very important role in Lao's economy. In 2004, medium enterprises numbered about 722 and small enterprises, 25,271. In term of employment, SMEs offer more than 60,000 job opportunities, which accounted for 40 percent of the country's total employment. To save Lao SMEs from the adverse impact of globalization, it is crucial to identify the issues confronting SMEs and evaluate the government policies and the impact of trade liberalization and FDIs on SMEs.

Despite the important role that garment SMEs play in SMEs in Laos, the termination of the Agreement on Textiles and Clothing (ATC) in December 2004 caused a shift in the global textile and garment industry in terms of trade and investment flows. The export value and employment of the garment industry were expected to decline (Unido, 2003). Moreover, the safeguard policy will be eliminated in 2008 and China will pose an even greater obstacle to Lao garment exporters. The government of Laos (GoL) would do well to formulate appropriate policies to support garment SMEs and enhance their competitiveness.

According to Kyophilavong (Kyophilavong, 2007), about 10 percent of establishments are performing well in Vientiane Municipality (VTM) and Other Provinces (OTP). In addition, about 20 percent of the SMEs in VTM and 17 percent in OTP are optimistic about the future of their businesses, saying they anticipated better business prospects. These show that economic prospects in Laos are favorable. Kyophilavong (Kyophilavong, 2007) said the obstacles to running a business in VTM and OTP are the same as the top four obstacles among SMEs in Laos, namely, high tax, high inflation, unstable exchange rate, and lack of fund (Table 2). Based on interviews with SME owners, the tax collection system lacks transparency (Lord Montague, 2006).

At the height of the Asia financial crisis during 1997-1998, Lao suffered like other affected countries in the region. Among the impacts on its economy was high currency (kip) depreciation that led

to hyperinflation. SMEs, in particular, bore the brunt of the crisis. These problems continue to hound SMEs. Until now, no banks or financial institutions provide credit support to SMEs. The banking sector in Laos is dominated by the state-owned Commercial Bank, which has limited assets and deposits and offers no credit facilities to SMEs. Moreover, the banking sector does not have incentives to provide credit to SMEs(Kyophilavong, 2008). Therefore, SMEs mainly depend on informal sectors for credit and funding. Based on the foregoing, what SMEs specifically need government to do is to ease their tax burdens and provide them with capital support (Kyophilavong, 2008).

Notwithstanding the important role of SMEs in the economy, by far there are few studies which have examined the factor influencing on the financial performance of SMEs in Laos(Kyophilavong, 2007; Souksavath, Kyophilavong, & Phoyduangsy, 2012; Southiseng, Ty, Walsh, & Anurit, 2008). Especially quantitative assessments of impacts of locus of control, need for achievement, risk-taking propensity, strategy making, and environmental uncertainty on firm performance are very limited in both number and scope(Souksavath et al., 2012; Uchikawa & Keola, 2008). Therefore, the main objective of this study is to examine the relationship between the aforementioned factors and the performance of SMEs.

2 Literature Review

Small and medium enterprises are recognized as one of the most important players in the economy regardless of the size of the economy. Even in a huge economy, take for example Japan, "large enterprises" and "SMEs" have always been coexisting in the so-called "dual structure." SMEs are often affiliated with and/or work as subcontractors or suppliers for large assembly firms in a vertical production network. Previously, SMEs were perceived as less efficient, having low technological and skill level, and temporary employment, etc. However, the image of SMEs has gradually changed as they have contributed significantly to Japanese industrialization. With their huge number, they have provided employment opportunities to a large portion of the labor force, created various industrial agglomerations, and enabled regional development (Ito & Ito, 1992).

In a global context of developing countries, SMEs are considered as the backbone of the private sector that has the potential for rapid growth in employment, income generation and poverty reduction (IFC, 2011). In a discussion on the role of SMEs in economic growth, it is argued that the contribution of small firms to an economy is related to higher growth but might not be pro-poor. Active and vibrant private enterprises can help enhance the effectiveness of aid projects in developing countries. Many SMEs in supporting industries and export-oriented industries have developed as part of a transnational production network or have been established by means of FDI, such as garment firms. Many of the foreign-owned SMEs (wholly or partly) would eventually grow and develop themselves to large enterprises.

On the other hand, the majority of domestic market-oriented establishments are SMEs which are often founded in cities having a relatively large population and sharing the border with Thailand or Vietnam, such as the Vientiane Capital City, Savannakhet Province, Champasack, Khammuan, Xayabury, Xiengkhuang, and Vientiane Province. For instance, most of SMEs in cottage industries are family business and groups of villagers producing and selling handicrafts to retail shops and the like. These middlemen (shop owners) would directly resell the products, or modify the fashions, or distribute them to domestic and foreign markets. One remarkable development event of enterprises of this type was the "One Village One Product" movement initiated by the Japan International Cooperation Agency (JICA) in 2002. The Lao version of this movement is the "One District One Product" (ODOP) movement. One major problem faced by SMEs in this category is the lack of information and coordination (Uchikawa & Keola, 2008). In addition to the asymmetric information issue, challenges facing SMEs in Laos include business climates (tax issues, red tapes, etc.), limited access to financial sources, and lack of labor skills (Onphanhdala & Suruga, 2010; Souksavath et al., 2012; Southiseng et al., 2008). Especially, enabling broader access to sources of finance and strengthening education and skill training for workers would enhance firm performance, attract more FDI, accelerate economic growth and reduce poverty (Onphanhdala & Suruga, 2010).

Number of studies have been carried out to assess the relationship between entrepreneur's characteristics and the performance of the SMEs. Within the broad category of owner-manager characteristics, five elements which are likely to influence the performance of a firm were suggested by Storey (Storey, 2006) such as age, gender, motivation, education, previous work experiences of the owner-manager. On gender of entrepreneur, Kentor (Kentor, 2001) and Chell (Chell, 2001) reveled that

most SMEs firms owned by men were bound to perform better than those owned by women. Jones-Evans (Jones Evans, 2000) emphasized that this difference could be arisen due to limited access to finance, stringent collateral requirements and women's double duties. On the effect of the age of the entrepreneur, the younger entrepreneur has the necessary motivation, energy and commitment to work and is more inclined to take risks as the older entrepreneurs are likely to have reached their initial aspiration. Basic education enhances the overall quality of the business owner by providing the basic numeric and literacy skills, thus increasing the chance of survival (Carter and JonesEvans, 2000). Some studies state that the fact that a business owner has a higher level of education seems to stimulate the growth and better performance of the firm, thus having an impact on survival, growth and performance (Hall, 2001). The converse argument is that SMEs entrepreneurs who have higher level of education generally achieved lower performance rates than those less well educated (Kenneth, 2006).

Cant and Lightelm (Cant and Lightelm, 2003) in a survey of small business failure maintain that entrepreneurs often have good ideas and are competent but they do not have a clue on how to run a business in an uncertain environment and have no underlying appreciation of business fundamentals. Professional experience has been cited as an important factor affecting many aspects of entrepreneurial firms. Experience takes many guises and breadth of experience is shown to be an important factor driving the performance of firms, with the number of previous jobs positively related to new firm performance (Lumpkin and Marvel 2007). Thapa (Thapa, 2007) reported that the likelihood of SMEs failure was also found to be associated with the owner/manager's work experience prior to business launch and education. The ability of the SMEs entrepreneur to motivate affects the performance of a firm. Beaver (Beaver, 2003) makes a distinction between positive and negative motivation. Positive motivation includes the perception of market opportunities for a product or service and the desire to make money while negative motivation encompasses dissatisfaction with an existing employer and threat of actual unemployment. Blackman (Blackman, 2004) showed that the characteristics of the entrepreneur would influence the following: market opportunity, ways of handling business challenges, personal achievement, employment creation, independence, improvement of social status, profit, growth target thereby having effect on the performance of the firm.

3 Materials and Methods

The objective of this study is to investigate factors influencing of small and medium enterprises in Laos. This study adopts a survey research design to achieve this objective. Data for the study were collected through a standardized questionnaire distributed among 100 owner managers selected from manufacturing SMEs in the Vientiane province. As there was no official list of SMEs established in the Province, 100 SMEs were selected through convenient sampling. In addition to descriptive analysis procedures, bivariate and multivariate analysis of hierarchical linear regression, ANOVA and Chi-square test procedures were used to determine the general relationship between the variables.

4 Results and Discussion

The results of the study show that the respondents have a high level of internal Locus of Control (LOC) and the need for Achievement (n-Ach) in their goal achievement process. Further, the results also prove that owner-managers willing to take a moderately high level of risk in their business activities. The results revealed that owner-managers are in lacking strategy making(Inmyxai & Takahashi, 2012; Onphanhdala & Suruga, 2010; Souksavath et al., 2012; Southiseng et al., 2008) behavior and facing a high level of uncertainty in their business environment. ANOVA shows that significant statistical differences between male and female owner on LOC, n-Ach and risk-taking propensity (RTP).

Table 1   Correlation Coefficients Matrix

Variable	Mean	LOC	n-Ach	RTP	Strategy Making	Environment Uncertainty
LOC	8.25	1.00				
n-Ach	4.35	0.58**	1.00			
RTP	3.36	0.35**	0.25**	1.00		
Strategy Making	3.56	0.12	0.65**	0.07	1.00	
Environment Uncertainty	3.34	0.10	0.38*	0.06	0.62**	1.00
Firm Performance	3.25	0.36**	0.34*	0.03	0.78**	-0.36**

*** Significance at 0.01*
* Significance at 0.05

According to the correlation analysis (Table 1), positive significance correlations were found between LOC, n-Ach with firm performance. Literature relating to the RTP suggests that RTP is positively influenced towards the firm performance, unexpectedly, no significant correlation found between RTP and firm performance. A significant positive relation was found between strategy making and firm performance, and it also identified as a mediating variable strengthens the relationship between an entrepreneur's traits and firm performance.

The moderated influence of environmental uncertainty on strategy making and firm performance were evaluated using hierarchical regression. Table 2 shows the ability of business strategy in explaining the higher variance of firm performance after inserting the variable of environment uncertainty to the model, that is, 47 percent to 48 percent. Partially, the influence of strategy making is positive toward firm performance, but the influence of environmental uncertainty is negative. This means that business strategy implemented by firms will motive firm performance; however, environmental uncertainty will weaken the achievement of good firm performance. The results also show that the interaction variable can explain the change in firm performance significantly (R^2 change by 0.029 and F change by -21.12, p = 0.00). Therefore, it can be concluded that environmental uncertainty is moderating variable towards the relationship between strategy making and firm performance.

Table 2   Regression Summary for the Moderator Variable

Independent Variables	Dependent Variable (Firm Performance)					
	B	p	B	p	B	p
Business strategy (BS)	0.72**	0.00	1.20**	0.00	7.43**	0.00
Environment Uncertainty (EU)	-	-	-0.43*	0.05	4.19**	0.00
Interaction BS x EU	-	-	-	-	-1.212	0.00
R2	0.45		0.56		0.419	
R2 change			0.04		0.121	
F value	132**	0.00	60.32**	0.00	52.14*	0.00

** Significance at 0.01
* Significance at 0.05

5 Conclusion

The aim of this study was to review some of the critical factors that may determine the performance of the SMEs in the Lao context. The study has revealed some important findings. It is also concluded that internal factors such as entrepreneur's internal Locus of Control and Need for achievement and strategy making are positively correlated with firm performance. Further, strategy making abilities of entrepreneurs are vital to achieve their desired business objectives and superior performance in the environment which is rapidly changing, competitive and hostility in the present arena. As the study was limited to only manufacturing SMEs in Laos, replication of the study in other industries, as well as other regions in the country, are needed to validate the current findings. Future studies should give due attention to investigate the benefit of entrepreneurship development and policy implementation in business promotion. To promote the development of the private sector, assessment of the quality and appropriateness of education deserves more consideration in the policy formulation for human resource development (HRD) and Private sector development (PSD). If the policy targets of the government of Laos (GOL) are to be attained, equally important will be needed for systematic monitoring and evaluation of policy implementation.

Grey Relational Analysis of Factors Influencing High-tech Service Industry in Hubei Province of China

Han Xue
School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: shixiaohanxueya@163.com)

Abstract: According to the 13th Five-year Plan of service industry in Hubei province, it is urgent to carry on strategies to upgrade service industry, promote its efficient and innovative development and thus build up a service industry highland of the middle and lower reaches of Changjiang River. This paper comprehensively uses the second-hand data analysis method and grey relational degree analysis method to study the factors that influence the development of high-tech service industry in Hubei province. It finds that researchers and R&D expenditure are the most important factors among others. Therefore, it proposes that Hubei province should increase scientific and technological input and improve facilities.
Key words: High-tech service industry; Grey relational degree; Innovation; Strategy

1 Introduction

With the development of productivity, the service industry has been recognized by many scholars as the upgrading of the national economy and the supply of labor market. High-tech service has been the subject of domestic research since the beginning of 21th century, mainly because of the fact that high technology in China began to develop in the century. Different scholars have different definitions of it: the main input factor of high-tech service industry is knowledge, with innovation input and innovation performance (Wei Jiang, 2003); high-tech service industry is the development of high-tech and modern management concept, mode of operation and organizational form (Zhou Zhenhua, 2005). High-tech service industry is the service industry, which is mainly affected by the process of industrialization and the division of social production, and uses modern technology, new service mode and new mode of operation to transform the traditional service industry (Xia Jiechang, 2007). The importance of the innovation in the high-tech service industry has also been affirmed by scholars, the knowledge-intensive service industry is one of the most important agents of technological change and economic growth (Yuan Lihong, 2007). The core of the high-tech service industry is to strengthen the customer participation in the innovation process, and promote the knowledge interactive delivery (Xiao Deyun, Xu Ke, 2013). Service innovation is considered to be the primary driver of innovation performance in a service environment (Chao-hung Wang, 2014).

2 Characteristics and Classification of High-tech Service Industry
2.1 Features of the high-tech service

As a product of technological progress, the high-tech service industry has different characteristics compared with traditional service industry. It has the following characteristics (Lu Weixia, Zhao Liang, 2014):

a. High-tech. High-tech service industry relies on high and new technology. Such information as the influence of macro-economic regulation on consumer's consumption habits can be made through data analysis to make better decisions. Thus, it is necessary to acquire high technology first in order to obtain more accurate information.

b. High added value. High-tech can bring higher service value, while improving the service experience can reduce the waste of resources.

c. High quality of employees. Only when they have a good command of the high-tech can the personnel provide better service.

d. High innovativeness. In order to sustain the competitive advantages in the high-tech service industry, an enterprise should strengthen the innovation of high-tech service industry and form the advantages of differentiation.

2.2 Classification of high-tech service

From the technology dimension high-tech service can be divided into new technology users, the carrier of new technology and the integration of new technology generation (Windrum, 1999); from the knowledge dimension, it can be divided into consulting service, electric business service and technical

service (JinXuejun, 2002); from the interactive dimension, it can be divided into the professional service organization and the mass production service organization(Silvesrour, 1992); from the source dimension, it can be divided into public science&technology service industry and enterprise science & technologyservice industry (Lee, 2003); based on the joint dimension, service dependency and service standardization, high-tech service industry is divided into technical knowledge service, peripheral support service and professional knowledge service industry (Qian Zhongqian, 2004).

3 Analysis of the Development of High-tech Service Industry
3.1 Advantagestatus quo of high-tech service industry in Hubei
The 12[th]Five-year Plan saw a rapid development of service industry in Hubei province,which is playing a more and more important role.

a. The scale of market continues to expand and market participants continue to grow. The growth of service industry in Hubei has kept increasing since 2010, with annual growth rate reaching 10.8%, higher than GDP growth of Hubei. Participants in service industry has also grown rapidly. Up to 2015, service enterprises have reached 65.45million.

b. Hubei is rich in human resources, with strong innovative potential. Hubei province is a talent gathering place, with the number of college students ranked top three and the number of senior technical personnel working in such as the Chinese Academy of Engineering ranked top five in the country.Human resource is the core resource and the core competitiveness of the development of high-tech service industry. In recent years, the number of accepted patents in Hubei is in the forefront of the country, and both the volume of accepted patents and approved patents have kept growing during the decade.

Table 1   Patent Situation in Hubei Province from 2005 to 2016

Project	Accepted Volume (a)				Approved Volume (a)			
	2005	2010	2015	2016	2005	2010	2015	2016
Total	11534	31311	59050	74240	3860	17362	28290	38741
Invention	2038	7410	22536	30204	733	2025	4855	7766
Utility model	4835	12792	27829	35676	2238	10431	19801	25298
Exterior design	4661	11109	8685	8360	889	4906	3634	5717

c. The contribution of service to economic development continues to increase. Finance, logistics, technology information, e-commerce and other modern service industry has accounted for 41.5%of service and have become an important part of the service industry.As to facilitate residents' life, the high-tech service industry, such as e-commerce and shared bicycles, has brought greater convenience to the residents.
3.2 Weakness status quo of high-tech service industry in Hubei
a. Brain drain. Hubei has more than a million college students each year, which is the necessary resource for the development of high-tech service in Hubei. However, the brain drain is very serious.Take Wuhan as an example, with 1.3 million university students, has the second largest number of college students, but brain drain is almost the most serious in China.According to the Antgold's report on university students employment flow in 2015, it shows the top five popular trans-provincial employment migration routes, respectively, Wuhan → Shenzhen, Wuhan → Beijing, Changsha → Shenzhen, Wuhan → Guangzhou and Harbin → Beijing. The main reason why college students can't stay in Hubei is that they are dissatisfied with salary and employment development, and there is a big gap between Wuhan and first-tire cities.

b. Insufficient funds of R&D investment. Until the end of 2010, population in Hubei has reached to 58 million,GDP per capita 50635.85 yuan,and investment in R&D for 5617415 million, which only accounted for 1.896% of GDP in Hubei. The GDP of third industry in Hubeiis 1273.7 billion, accounting for 42.65% of the GDP. It shows that the development of high-tech service in the tertiary needs to be improved, and the government should increase the investment in R&D.

c. Lack of adequate hardware facilities. Infrastructure is the foundation for the development of high-tech industries, including transportation, servers, machinery and equipment, housing and so on. Regions equipped with advanced infrastructure canattract more talents and enterprises gathering. The infrastructure construction of Hubei is not perfect, mainly are:i. not equipped with advanced infrastructure to appeal talents; ii. the real estate problem of high-tech industry area is also a factor restricting the development of high-tech industry. Due to the industrial cluster effect, the store of the

industrial park has become the target of the real estate business, which will make some companies in the high-tech service industry move out of the park because they can't afford the exorbitant rents, which has affected the innovation development of the whole high-tech industry. For instance, 798 Cultural Creativity Zone in Beijing, because the rent is too high, many companies moved out of the park.

4 Grey Relational Degree Analysis

For a factor between two systems, the measurement of the degree of association that changes over time or between different objects is called the correlation degree. In the process of system development, if the trend of two factors is consistent, the degree of synchronization change is high, so the correlation degree is high; if not, the correlation degree is low. Research has shown that there is a positive correlation between science and technology input and industrial economic growth, but the impact of science and technology input on high-tech service industry is still under study, this paper introduces science and technology input as the first research variable which is expressed by R&D funding and scientific activity personnel.

Region with high level of economic development, the value of the service industry will also be higher. High-tech service industry acts as an important part of the service industry, whose development closely related to the whole service industry, which provides a good market environment for high-tech service industry, should be relevant to economic development. The level of economic development is expressed in terms of GDP per capita. And as people's income rises, many new requirements are created, such as VR experience, unmanned aerial aircraft technology, etc. The higher the level of consumers' demand is, the higher the likelihood that high-tech service will be consumed. The level of consumption demand can be expressed in CPI.

In comprehensive, in the grey relational degree analysis, R&D funding, scientific activity personnel, GDP per capita and CPI these four variables are introduced. Because of the lack of access to the production of high-tech service, so here the value of added production is used as another system variable of high-tech service industry. Due to different statistical calibers, the added production of high-tech service was not counted before 2012, therefore, only data from 2012-2016 will be analyzed. MATLAB is used to analyze the influence of these four factors on the added production of high-tech service industry. Table 2 shows the value of these five variables from 2012 to 2016 (The data come from the Hubei provincial statistical yearbook 2013-2017).

Table 2   Value of Five Variables from 2012 to 2016

year	R&D funding (10000 yuan)	Scientific activity personnel(Person)	GDP per capita (yuan)	CPI (%)	added production of high-tech service (million yuan)
2012	3845239	339786	38572.33	1444.3	258.3
2013	4462690	365502	42825.76	1597.4	337.9
2014	5108973	388430	47144.60	1769.9	467.88
2015	5617415	378828	50653.85	1932.7	609.04
2016	6000422	393333	55038.40	2120.2	726.67

The steps are as follows:

a. Set $\{X_i, X_J, X_k, X_l, X_m\}$ as R&D funding, scientific activity personnel, GDP per capita, CPI and added production of high-tech service industry the grey system that forms, where X_i represents i variables from 2012-2016, $x_i= \{x_i(1), x_l(2) ... x_i(5)\}, X_i, X_j, X_k, X_l$ are for comparison series, X_m is a reference sequence.

b. Make the variabledimensionless. Because the data in each factor column of the system may be different in dimension, it is difficult to compare or to get the correct conclusion in comparison, so we should first eliminate the influence of dimension. In this method, the average value of each sequence is compared with the average of the whole sequence, thus new series $\{ X_i', X_j', X_k', X_l', X_m'\}$ are obtained.

c.Handle parameters. Setting the difference series between series X_i' and series as a new series:

$$\Delta_{i,m} =(\Delta_{i,m}(1) ... \Delta_{i,m}(5)),\tag{1}$$
$$\Delta_{i,m}(') =| X_i'-X_m' |,\tag{2}$$

setting the difference series to $\{\Delta_{im}\}$;

setting environment parameter, $\Delta max = \max_{i} \max_{m} \{max\Delta_{i,m}(')\}$, (3)

$$\Delta min = \min_{i} \min_{m} \{min\Delta_{i,m}(')\},$$ (4)

setting resolution factor $\zeta=0.5$;

   d. Calculate association coefficients:

$$r_{i,m}(') = \frac{\Delta min + \zeta \Delta max}{\Delta i,m(') + \zeta \Delta max},$$ (5)

   grey relational degree:

$$r_{i,m} = \frac{1}{5} \sum_{,}^{5} = 1 r_{i,m}(')$$ (6)

Repeat steps c, d, r_{jm}, r_{km}, r_{lm} can be calculated separately, and results shows in figure 1, these four factors all have strong impact on high-tech service industry, especially R&D funding and scientific activity personnel. According to China statistical yearbook (2017), GDP per capita in Hubei is ranked 11[th,] and CPI is ranked in 13th, and science and technology input has grown a lot, which contributes a lot to the development of this industry in Hubei. However, there is big gap in technology input in comparison with other provinces, where needs more efforts-making.
Figure 1   Result of Grey Relational Degree About High-tech Service Industry

5 Innovative Development Strategy for High-tech Service

According to the problems encountered in the development of high-tech service industry in Hubei and the results of grey relational analysis, the following strategies are proposed:

a. Government should increase its investment in high-tech service. In recent years, the R&D funding in Hubei has grown, until year 2016 has grown to 56178 million, but compared to Zhejiang and Jiangsu, whose R&D funding is far more than that Hubei, increased investment is needed. The differentiation advantage of high-tech service industry is embodied in the innovation of science and technology, but innovation is accompanied by high cost and high risk. Many enterprises can only be deterred from innovation, so the government should provide some policy support to encourage innovation. By providing low-interest loans, tax concessions and various subsidy policies, the provincial government can increase its investment in enterprise research and development, thus reduce cost of innovation and reduce risk of innovation and increase the enthusiasm of enterprise innovation. Enterprises should also take advantage of the support of government to strengthen the research and development capabilities of the enterprise, to promote the industry's technological innovation.

b. Strengthen talent retention and achievement transformation in high-tech service industry. The shortage of talents in high-tech service industry is an important restricting factor for the slow development of high-tech service industry in Hubei. Besides R&D funding, scientific activity personnel is another part of technology input. On the one hand, it is important to cultivate a group of high-tech service personnel by cooperating with colleges and universities, fully tap the talent resources; on the other hand, creating a good employment environment, while improving the salary of college students.

The scientific research institutes in Hubei have accumulated a lot of scientific research achievements such as patents and technology, some of which are cutting-edge achievements, but the industrialization of scientific and technological achievements in Hubei is seriously insufficient. Therefore, the scientific and technological service intermediary in Hubei should strive to promote the effective transformation of scientific and technological achievements in the area. For one thing, overcome the institutional mechanism obstacles to the transformation of scientific and technological achievements, resolutely implement the central and Hubei policy measures on encouraging the transformation of scientific and technological achievements; for another, organize the scientific research

institutes in Hubei and the relevant enterprises, especially small and medium-sized enterprises and entrepreneurial enterprises interaction, narrowing the cognitive gap between the two sides, transferring scientific and technological achievements to specific industrial development projects.

c. Perfect hardware facility configuration. On the one hand, we should strengthen the facilities allocation of transportation, logistics and so on, so as to reduce the transaction cost of enterprises; on the other hand, we should actively establish industrial park and absorb enterprises to enter the park, creating a good environment for high-tech service enterprises andforming industrial cluster effect.

d. Encourage the service sector to increase the level of openness. Government should encourage the high-tech service enterprises in Hubei to learn experience from other regions, especially like Beijing, Shanghai and Guangdong; in the area of international cooperation, government should make efforts to attract foreign enterprises to invest in Hubei or set up branch offices, which can introduce new technology to Hubei, and encourage enterprises in Hubei to step into the international market and open their horizons, so better know how to improve the high-tech service industry in Hubei to accelerate its development.

6 Conclusion

Through the grey relational degree analysis, this article obtains the most important two factors that influencing the development of high-tech service in Hubei are R&D funding and scientific activity personnel, and GDP per capita and CPI also have strong impact. Combined with the problems in the current development of high-tech service industry in Hubei, countermeasures of strengthening the innovation and development of high-tech service industry are put forward: government should increase investment in high-tech service, strengthen talent retention and achievement transformation in high-tech service industry, perfect hardware facilities configuration and encourage the service sector to improve the level of openness.

This paper only discusses the development of high-tech service industry in Hubei province, the scope of research is relatively narrow, and the factors introduced in grey relational degree analysis are relatively not sufficient, and the analysis is not comprehensive enough. It is hoped that the future research will be able to study the problem in a larger scope and introduce more factors which affect the development of high-tech service industry to drive the development of this industry.

Research on Financing Efficiency of Technology Based on SMEs in NEEQ Market: A Case Study of Beijing

Lian Junsha, Li Ke
School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: 793234412@qq.com, 22870946@qq.com)

Abstract: Technology-based SMEs are the driving force and important carrier for promoting China's economic development, but their financing difficulties have not been resolved. This article uses the DEA model based on the financial data of the Beijing technology-based SMEs in the NEEQ for the period from 2015 to 2016, from the financing of input and output as the breakthrough point, the financing efficiency of around 2015.Results found that NEEQ market met the financing needs of technology-based companies and its efficiency increased after financing. However, there were still serious problems such as serious capital idling, low capital utilization and excessive scale expansion. Finally, this paper puts forward some suggestions to further enhance the financing efficiency of enterprises from three aspects: the technology-based SMEs,the NEEQ market and the government.
Key words: Technology-based SMEs; NEEQ market; Financing efficiency; DEA model

1 Introduction

Technology-based SMEs are the main carrier of China's technological innovation and an important driving force for economic growth. Although the state attaches great importance to the development of technology-based SMEs, and various departments are encouraged to take various measures to support the development of SMEs. However, the innovation and development of China's technology-based SMEs still face many problems. The establishment of the NEEQ has improved the financial environment of SMEs and has played a significant role in actively promoting the healthy, stable and sustainable development of financial in China. Due to the economic system, foreign scholars have less research on financing efficiency, and there are many domestic research articles on enterprises finance efficiency and the NEEQ. In the research on financing efficiency, applying the DEA model to find that the financing efficiency of SMEs listed on SME board and the GEM is generally inefficient (Gao Shan, 2010); Using the DEA-Malmquist index method to find out the financing efficiency of China's technology-based SMEs, the financing efficiency of China's SMEs is low, and there is a waste of input resources (Wu Juan, 2012); Using the DEA model to measure the financing efficiency of SMEs listed on SME board and the GEM found that its resources have not reached the optimal allocation (Song Guanghui,2017). Although the NEEQ market has eased the problem of financing difficulties, its mechanism still has many problems(SuYa, 2015). The paper selects the research object of the technology-based SMEs, which reduces the bias caused by the individual differences between the research objects in the analysis process. At the same time, the selection of Beijing technology-based SMEs financed by the NEEQ Market as a sample to reduce the influence of regional differences on the analysis.

2 Research Methods

2.1 Model selection

DEA was proposed by the famous American operations researcher Charnes,Coper and Rhodes in 1978. It is a mathematical programming method for the relative effectiveness of homogeneous decision-making units (DMUs). Its essence is to calculate the weight of each input and output variable of the DMU. C^2R and B^2C are two basic models of DEA. The premise of using the C^2R model is the assumption that the scale returns are unchanged and the technical efficiency (TE) is obtained. The technical efficiency index can be decomposed into pure technical efficiency (PTE) and scale efficiency (SE). The technical efficiency of a company when pure technical efficiency is changed by scale returns can be solved by the B^2C model. Assume that there are no decision units, each of which has K inputs and M outputs. Under the assumption of constant scale returns, the C2R model of DEA input Angle:

$$Min_{k,1}K$$
$$s.t.\, Y_1 - y_j \geq 0, k_{x_j} - X_1 \geq 0,1 \geq 0 \tag{1}$$

Under the assumption of variable returns on scale, the B^2C model of DEA input perspective:

$$Min_{k,1}K$$
$$s.t. Y_1 - y_j \geq 0, k_{x_j} - X_1 \geq 0, I_1 = 1, 1 \geq 0 \qquad (2)$$

Among them, for the first j decision unit, the K-dimensional input column vector and the M-dimensional output column vector are represented by x_j and y_j, respectively, and X and Y represent the input data matrix and the output data matrix of the n decision units respectively. For K rows and N columns and M rows and N columns of matrices. I am used here to represent an n-dimensional row vector whose elements are all 1. l is an n-dimensional column vector whose elements represent the weight of the corresponding decision unit.

2.2 Selection of indicators

Technology-based SMEs are characterized by high investment, high risk, high profit and fast growth. Therefore, it is necessary to determine the input and output indicators that meet the characteristics of the enterprise in order to correctly use the DEA method. Considering the scientificalness and effectiveness of data, this paper selects three input indicators and three output indicators.

Table 1   Input and Output Indicators

Financing efficiency index	Index name	Index meaning
Input indicator	Total assets	Reflects the size of the company
	Main operation cost	Reflects the ability of the company to use assets
	Debt to assets ratio	Reflects the impact of capital structure on financing efficiency
Output indicators	Return on equity	Measures the efficiency of corporate capital operations
	Main operation income growth rate	Reflects the company's future development capabilities
	Total assets turnover	Reflects capital operating capacity and internal management

2.3 Data selection and source

The paper selects Beijing as a case. It mainly considers that Beijing is one of the most economically active cities in China. Technology-based SMEs cover a wide range of industries and are representative. This article selects the technology companies that were listed on the NEEQ in Beijing from 2014 to 2016, and excluding those companies that have been delisted, incomplete financial statements and abnormal financial conditions, a total of 45 sample companies have been selected. The data comes from the company's annual financial report and the WIND financial advisory database disclosed on the official websites of the exchanges.

3 Empirical Research

3.1 Statistical description of the sample

Data of input and output indicators were obtained from the annual reports of each sample company in 2014, and their mean values were calculated. The statistical results were shown in table 2 and table 3.

Table 2   Input Indicators

Asset size (10000 ￥)	Number of companies (45)	Debt to assets ratio(%)	Number of companies (45)	Main operation cost(10000 ￥)	Number of companies (45)
≥10000	3	≥80	1	≥6000	2
7000-10000	1	50-80	10	4500-6000	1
4000-7000	6	20-50	24	3000-4500	6
1000-4000	31	<20	10	1500-3000	8
<1000	4	—	—	<1500	28
Mean	3172.95	Mean	35.53	Mean	1797.34

Table 3   Output Indicators

Return on equity(%)	Number of companies (45)	Main operation income growth rate(%)	Number of companies (45)	Total assets turnover(%)	Number of companies (45)
≥40	8	≥100	10	≥200	8
30-40	2	70-100	3	160-200	7
20-30	7	40-70	7	120-160	10
10-20	8	10-40	13	80-120	10
0-10	18	0-10	7	40-80	8
<0	2	<0	5	0-40	2
Mean	23.72	Mean	72	Mean	141.23

In table 2, companies with total assets of 10-40-million-yuan account for 68.89% of the total number of companies, and the average asset size of the sample company is less than 40 million yuan., and the main operation cost is relatively low, with an average of 17.97 million yuan.The average debt-to-equity ratio is 35.53%, and the asset-liability ratio of more than half of the companies is less than 50%, indicating that the debt-to-asset ratio of selected SMEs in Beijing is relatively low.

In table 3, 40% of the company's return on equity is 0-10%, the average value of sample companies is 23.72%; the growth rate of main operation income is higher than 100% of the companies reached more than 22% of all companies. It can be seen that the technology-based SMEs in Beijing had strong growth before they were listed;The mean value of total assets turnover rate is 141.23%, and the total assets turnover rate of 35 companies is over 80%, accounting for 77.78% of the company. Among them, the total assets turnover rate of 8 companies is over 200%, which reflects that the total assets turnover rate of the sample company is relatively high.

3.2 Financing efficiency static analysis

The C^2R model and the B^2C model were constructed using the input and output indicators before financing, in the year after financing, and in the second year after financing, selected from the raw data of 45 sample companies listed on the NEEQ market in Beijing. The data envelopment analysis software DEAP2.1 calculates the financing efficiency and obtains the average financing efficiency of the sample companies in 2014,2015 and 2016. The calculation results are shown in Table 4:

Table 4   The Mean Value Financing Efficiency of Sample Companies

The efficiency of the mean	TE	PTE	SE
Before financing(2014)	0.408	0.622	0.600
After financing(2015)	0.542	0.725	0.691
Follow-up financing(2016)	0.556	0.681	0.799

As can be seen from table 4, whether it is TE, PTE or SE,the average value of 45 sample companies in Beijing after financing is greater than that before financing. Among the 45 sample companies, the technical efficiency (TE), scale efficiency (SE) and pure technical efficiency (PTE) after financing were higher than the number of enterprises before financing, which were 26, 29 and 26, accounting for 57.78%, 64.44% and 57.78%, respectively, of the 45 sample companies. It can be seen that the financing efficiency of financing has been further improved.

3.3 Dynamic analysis before and after financing: 2015-2016

The static financing efficiency of selected sample companies in 2015 has not yet fully demonstrated their overall situation. So, we can compare the financing efficiency of 45 companies listed in Beijing in 2015 and 2016. From Table 4, we can see that in addition to the average value of pure technical efficiency lower than 2015, the average financing technology efficiency and scale efficiency in 2016 are higher than in 2015.
Figure 1　Comparison of Effective Financing Efficiency of Sample Companies

From figure 1, we can see that after listing on the NEEQ market, the financing efficiency of enterprises tends to increase. The increase of financing efficiency in 2016 is the main reason for the improvement of the financing technology efficiency. This is also consistent with the trend of China's vigorously supporting technology-based SMEs. With the introduction of some national policies, and the development of financing platforms becoming more and more standardized, it can be seen that the financing efficiency of Beijing's SMEs is gradually improving. It shows that technology-based SMEs are vulnerable to the impact of national policies, and the improvement of their financing efficiency is closely related to the country's environment. However, the majority of companies still experience diminishing returns to scale. Therefore, the scale should be appropriately reduced and funds should be invested in efficient projects. The reduction in pure technical efficiency also indicates that it should increase its technical level of input, increase output, and reduce the problem of redundant funds.

4 Conclusion

By using the DEA model to calculate and analyze the financing efficiency of 45 technology-based SMEs in Beijing before and after financing, we can find that the financing efficiency of the technology-based SMEs has been improved, and the NEEQ market to a certain extent, to satisfy the small and mid-sized enterprise financing needs, but after the financing of SMEs, there are serious idle funds, low capital utilization, and excessive expansion. For this reason, based on the above research, we can propose suggestions for further improving the financing efficiency of SMEs:

4.1 Suggestions for Technology-based SMEs

First, technology-based SMEs strengthen innovation and upgrade their core competitiveness. For technology-based companies, innovation is the driving force for development. Second, companies must enhance the efficiency of the use of funds and avoid the idle and waste of funds. They should maintain a moderate expansion strategy, control their own development scale and improve the efficiency of resource. Third, companies choose the right financing method. Whether it is listed on the NEEQ, the Main Board or the Growth Enterprise Market, the most important thing is to adapt to own financing needs and consider the financing costs of the listing.

4.2 Suggestions for the NEEQ market

On the one hand, the internal mechanism should be improved to strengthen the review and screening of listed enterprises.The NEEQ market just started running, due to the internal screening mechanism is not perfect enough, and the financial threshold is low, which leads to the lack of attention to the integration of funds after listing, making the development and financing of enterprises in an inefficient state. On the other hand, we must improve the transfer and delisting mechanism of the NEEQ market and accelerate reform of the market-making business system. Improving the mechanism of refunding can stimulate the development of enterprises and provide a good financing environment.

4.3 Suggestions for the government

On the one hand, as the supervisory department of the industry, the China Securities Regulatory Commission must actively maintain a fair, open and fair market environment for the NEEQ market and maintain a good market order. The government must strengthen its guiding role and introduce relevant support policies. Therefore, the government can optimize the technology and financial environment and increase financing channels through various financial intermediaries such as venture capital guidance funds, policy guarantee institutions, and technology sub-branches.On the other hand, we must strengthen

the construction of multi-tiered capital markets and promote the rapid development of SMEs. With the gradual increase of the thresholds for the listing of small and medium-sized boards and GEM, the NEEQ market and the regional equity transfer market have become the best choice for technology-based SMEs in the seed period, start-up period and growth period to get out of financing difficulties.

Impact of Institutional Ownership on the Corporate Governance

Lin Bo

School of Business, Wuhan Huaxia University of Technology, Wuhan, P.R.China, 430223

（E-mail: 258382150@qq.com）

Abstract: A great number of enterprises reform the ownership structure, for the sake of improving the corporate governance structure and promoting financial performance. Actually, institutional ownership plays a positive role in improving the corporate governance. Company managers are expected to introduce institutional ownership, so impact of institutional ownership on the corporate governance becomes the hot spot atpresent. In this article, after introducing the classification and features of institutional investors, the author analyzed the participating mechanism of institutional investors in corporate governance, selected the financial data of listed companies as samples, and constructed the mathematical model for statistical analysis, the result shew that there was a positive correlation between institutional ownership and financial performance. Finally, the research proposed suggestions on developing the governance role of institutional investors.

Key words: Institutional investors; Corporate performance; Corporate governance; Ownership structure

1 Introduction

In China, since listed companies generally have the ownership structure of the single-large shareholder. In addition, considering omission of other governors, it is common that substantial shareholders encroach on interests of corporations. Learning from western countries, institutional investors develop an important role on corporate operation and supervision. As a result, the supervision department places great hopes on institutional investors, which will develop a positive effect on corporate governance.

It is widely believed that the academic circles have the diverse comprehensions on institutional investors. The Western Scholars(Davis, Steil, 2001) described institutional investors as special financial institutions and gathered medium and small investors together to stand for their interests, engaged in investment activities in the specific range of time and risks, and pursued for benefit maximization. The Chinese scholars(Zhou Zhengqing, 1998) enumerated institutional investors as eight categories including insurance companies, securities companies, social insurance funds, securities investment funds, and qualified foreign institutional investors(QFII) in the Textbook of Securities Knowledge.

From the perspective of the relationship between institutional investors and corporate governance, after scholars(Bushee, 2000) investigated more than 200 institutional investors, the author found that when these investors make an investment decision, they pay more attention to the corporate governance status in line with investment status. In addition, the study of professor (Mcconnell, Servaes, 2003) also showed that the stocks held institutional investors have the positive correlation. While the study of Chinese scholars (Wang Kun, Xiao Xing, 2005) indicated that Chinese institutional investors can participate in the corporate governance activities to some extent. The professor(Li Qiang,2015）selects listed companies in China as the research object, and concludes that institutional investors' shareholding can promote the performance of enterprises. The author(Xu Qin, 2016) believes that the regulatory mechanism of institutional investors in China's capital market is not perfect, which is not conducive to the improvement of corporate performance. Comprehensive domestic and foreign research, because of large investment, institutional investors have the power to supervise the operation of the enterprise and assess the management activities, thus promoting the improvement of the enterprise financial performance level.

2 The Mechanism Analysis for Institutional Investors to Participate in the Corporate Governance

By making a comparison between institutional investors and individual investors, institutional investors have the following features: (1) Professional project management: institutional investors generally set up a professional department in information collection, corporate study, and decision-making analysis. Experts will be responsible for operation, but individual investors are often lack of professional knowledge and skills. (2) Structural modularization: capital of institutional investors gather the idle funds, so they are relatively sensitive to capital safety and risks. In order to reduce the

investment risks, institutional investors often devote themselves to optimizing investment structure. In fact, individual investors often have limited capital, so they are hard to do the effective portfolio. (3) Behavior standardization: institutional investors are economic entities with status of a legal person, so their investment behaviors are supervised in multiple aspects. At the same time, in order to improve investment earnings and maintain customer interests, institutional investors will autonomously standardize their investment behaviors （Xu Meifang, 2010）.

Corporate governance refers to supervise and balance operators by subsidiary corporation owners, including the governance structure constituted by shareholders, directors, supervisors and managers. Just institutional investors are equipped with the above-mentioned features, so they own the stock voting right for units to be invested, so as to participate in the governance activities through communication with managers, performance assessment and proposal of shareholder, improve management efficiency of the companies, gain investment earnings and reduce investment risks.

2.1 The mode for institutional investors to participate in the corporate governance

Collection of voting right: under the circumstance with the scattered stocks, a single shareholder holds few shares, so it is hard to play a decisive role in voting in the general meeting of stockholders, thus when institutional investors express different opinions and strive for voting right, they can collect stock voting right of other minority shareholders, so as to reinforce its role in decision-making and governance by virtue of proxy voting.

Communication with managers: institutional investors can positively communicate with company managers through board meeting, private meeting, visiting and investigational studying to effectively discuss investment decision-making and governance structure.

Proposal of shareholders: when the power of institutional investors is constantly expanded, their proposal is hard to be neglected by company managers. Particularly, when the proposal of institutional investors gains the higher approval rating, this proposal becomes the weight of institutional investors to negotiate with managers.

Performance assessment: institutional investors can exert pressure on company managers by evaluating board of directors and assessing corporate performance. Meanwhile, institutional investors can link corporate performance with managers of directors' salary, so as to affect the corporate governance.

2.2 Effect of institutional investors to participate in the corporate governance

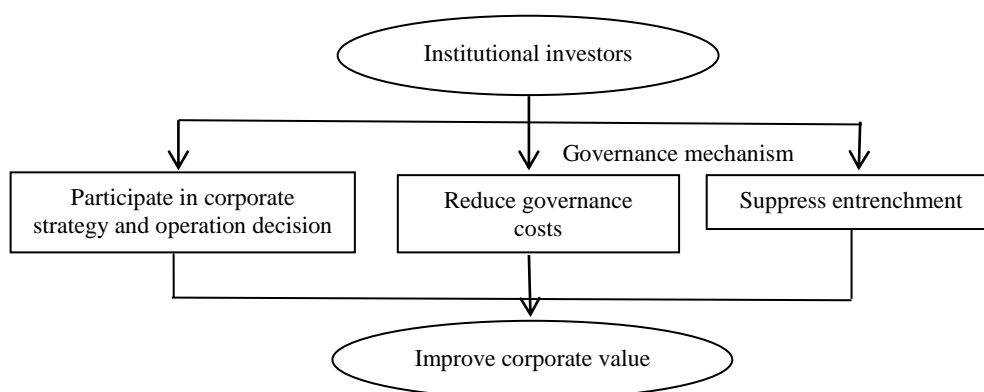
They can reduce governance costs and form economy of scale. Institutional investors can gather idle funds to invest. With the expansion of capital scale, governance costs of apportion per share are decreased (Huang Qian, 2009) At the same time, due to large capital trading volume, it is easy to form the economy of scale.


Figure 1　Mechanism for the Institutional Investors to Participate in Corporate Governance

When institutional investors participate in corporate governance, they can reduce dilemma of the single investor. Since the single investor holds few shares, the power is limited. Therefore, it is difficult to do effective communication with company management and hard to master full information, thus it is not good for participating in the corporate governance, so as to form the dilemma of the single investor. Institutional investors gather idle funds and have more shares, so they are relatively easy to participate in the corporate governance.

When institutional investors participate in the corporate governance, they can restrain entrenchment

of controlling shareholders (Wu Xiaohui, Jiang Yanfu, 2006). Controlling shareholders use their status and information asymmetry and utilize related-party transaction and malignant bonus to embezzle company property and damage interests of minority shareholders. Institutional investors can utilize information control and stock voting right to restrain entrenchmenteffectively.

3 Correlation Analysis Between Shareholding of Institutional Investors and Financial Performance

3.1 Research hypothesis

Institutional investors participate in corporate governance to implement the direct supervision on the management. They have the stock selling right in the secondary market, so as to indirectly supervise managers. All of these can promote management to improve the corporate governance and improve financial performance. In addition, it is good for institutional investors to gain the higher investment earnings.

As a result, this author in this thesis showed that shareholding of institutional investors can promote the improvement of financial performance, thus the author proposed the research hypothesis in this thesis.

Hypothesis: there is a positive correlation between shareholding of institutional investors and financial performance.

3.2 Sample selection

In this thesis, the author selected financial data disclosed by A-share listed companies in Shanghai and Shenzhen from 2009-2016 and treated with it in a necessary manager, including eliminated ST and *ST listed enterprises and eliminated incomplete enterprises of data disclosure. In the end, the author gained 10320 samples. After conducting the preliminary statistics, the author used Stata software for analysis.

3.3 Variable design

Dependent variable: the return on total assets of enterprises was used to measure the financial performance, marked as IAROA.

Independent variable: shareholding ratio of institutional investors was measured by using the absolute shareholding ratio and relative shareholding ratio, marked as INSH and Balance, respectively.

Regulated variable: the factor affecting the financial performance was designed as the regulated variable, including SIZE, R&D, LEV and GROWTH.

Table 1   Variable Design and Explanation

Types	Name		Marks	Notes
Dependent variable	Financial performance		IAROA	If the return on total assets is larger, it shows that financial performance of enterprises will be higher.
Independent variable	INST	Absolute shareholding ratio	INSH	If the sum of investors' shareholding ratio is higher, it shows that institutional investors have the higher occupation in stock rights.
		Relative shareholding ratio	Balance	The specific value between institutional investors' shareholding ratio and controlling shareholders' shareholding ratio
Control variable	R&D		R&D	Specific value of innovative input in business incomes
	LEV		LEV	Specific value between total liabilities and total assets
	SIZE		SIZE	Absolute number of total assets
	GROWTH		GROWTH	Growth rate of business incomes

3.4 Model construction

In order to demonstrate the hypothesis in this thesis, the following regression model was constructed:

$$IAROA = \beta 0 + \beta 1 INSN + \beta Balance + \beta R\&D + \beta 4 LEV + \beta 5\ SIZE + \beta 6\ GROWTH + \varepsilon \qquad (1)$$

3.5 Result analysis

As shown in Table 2, the regression coefficient between the absolute shareholding ratio of institutional investors(INSH) and financial performance IAROA was 0.438, while the regression coefficient between relative shareholding ratio Balance and financial performance IAROA was 0.402,

indicating that absolute shareholding or relative shareholding passed the significance testing, showing that there was the positive correlation between shareholding of institutional investments and financial performance.

Table 2   Statistical Analysis Table

Variables	IAROA		
	B	T	P
Con_s	0.661	5.93	0.0031
INSH	0.438	4.93	0.0044
Balance	0.402	4.64	0.0015

4 Suggestion on Reinforcing Institutional Investors to Participate in Corporate Governance

4.1 Cultivate diversified institutional investors

Shareholding of institutional investors has the important role on improving corporate governance, thus it is necessary to promote harmonious development of institutional investors, cultivate diversified institutional investors, expand social security funds and scale of entry for pension funds, and broaden admission of QFII, while stabilizing securities investment funds.

4.2 Guide institutional investors to develop a positive role on corporate governance

Institutional investors develop a positive role on the corporate governance by virtue of stock voting right and right of making motions, so as to improve financial performance. As a result, it is necessary to positively guide governance role of institutional investors and support in-depth participation in corporate governance and supervision in policy-making and system design.

4.3 Optimize ownership structure and create conditions for introducing institutional investors

In China, since ownership structure of listed companies is irrational, controlling shareholders become the single-large shareholders. Hence, controlling shareholders occupy the absolute predominance in the corporate governance and they often embezzle interests of corporations. To sum up, it is imperative to reform the ownership structure in listed companies. Institutional investors can be positively introduced in the reform with certain ratio and this is good for main shareholders to balance each other and improve governance level of the companies.

4.4 Reinforce supervision on institutional investors

Capital of institutional investors is originated from investment individuals. The capital earnings and safety influences are extensive, thus it is necessary to reinforce supervision of institutional investors' investment behaviors, intensify capital delegation responsibilities, and implement the effective performance assessment on fund managers, promote rational investment of fund managers, reduce risks, and positively develop governance role of institutional investors.

5 Conclusion

It can be observed from the above-mentioned analysis that shareholding of institutional investors exactly will improve corporate governance structure, so as to improve financial performance. After multiple years of development, Chinese institutional investors have certain scale with the development of capital market, but the effect in corporate governance is not enough, because institutional investors don't have enough cognition on participation in corporate governance. As a matter of fact, institutional investors in corporate governance can enhance corporate performance and it is mutually promoted with the development of institutional investors. Under the background of sound development in the capital market and improvement of governance in listed companies, it is necessary to cultivate the diversified institutional investors and develop the positive governance effect.

In this thesis, the author studied the relationship between shareholding of institutional investors and corporate performance, drew a conclusion that institutional investors can improve corporate governance. However, the author didn't conduct the in-depth study on specific performance of institutional investors in the corporate governance behaviors, so it is expected that the author will further discuss it in the future study.

Executive Incentives, Innovation Investment and Enterprise Growth

Luo Mengan
School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: luomengan@qq.com)

Abstract: In order to explore the relationship among the top management incentive, the innovation investment and the enterprise growth, this article takes the GEM listed companies as the research object, selects the data from 2014 to 2016 as samples, and applies multiple linear regression analysis. The results show that, (1)The executive incentive of payment and shareholding are both positively related to corporate growth. But the correlation between promotion incentive and corporate growth is not significant. (2)Either the implementation of compensation incentive or equity incentive is conducive to the promotion of investment on innovation projects, while promotion incentives have no significant effect on corporate innovation investment. (3)Innovation investment plays an intermediary role in the effect of executive incentive on enterprise growth.
Key words: Executive incentives; Innovation investment; Enterprise growth; Mediating effect

1 Introduction

Now China is in an important stage of economic transformation. Efforts to carry out innovation-driven strategies, to develop High-tech business, help improve China's capital market and promote the sustainable socioeconomic growth. With the development of technology, technological economy leaded by science is becoming a new form of economic development. Technological innovation has gradually become one of the ways for the enterprise to seek the long-term development. In the GEM market, which is dominated by high-tech enterprises in China, the demand for improving the ability of independent innovation is more intense.

Foreign and domestic scholars hold different views on the relationship between executive incentives and corporate performance.Mehran (Mehran, 1995) finds that CEO compensation incentives are the driving force behind CEOs' ability to improve company performance and corporate performance is positively related to CEO shareholding. Sesilt et al. (Sesilt et al., 2007) and Frye (Frye, 2001) find that companies provide employees with more equity incentives perform better.Kothari (Kothari, 2005) obtains empirical data from relevant companies in three countries: Higher level of executive incentives exists in enterprises with better growth ability, and the level of executive incentives is positively correlated with performance.Marianna et al. (Marianna et al., 2006) use panel data analysis to study the relationship between executive stock ownership and corporate performance in listed companies in the United States.The results proved that with the increase in the number of stock options held by executives, executive stock holdings will have a certain positive impact on corporate performance. Gasparyan and Gasparyan (Canarella G, Gasparyan A, 2008) show that there is a significant positive correlation between executive currency compensation and company performance.Some Chinese scholars believed that there is no significant positive correlation between executive compensation and corporate value. Due to the interference of external factors, the effect of China's listed companies on the compensation incentives of executives is not satisfactory, and it is necessary to further optimize the corporate governance mechanism to enhance the effect of executive compensation incentives (Zhou Yean, 2000; Wei Gang, 2000). Chen Xiaohong et al. (Chen Xiaohong et al., 2007) confirm that the growth of small and medium-sized companies is significantly positively correlated with management's salary and there is a significant U-shaped relationship with shareholding ratio, indicating that salary incentives and moderate equity incentives have a positive impact on the company's growth.Hou Jianping, Li Yunxin (Hou Jianping, Li Yunxin, 2015) divide executive incentives into compensation and equity incentives. After using EVA to measure performance indicators, it is concluded that executive incentives promote corporate performance, while corporate performance also promotes executive incentives to a certain extent.

Himmelberg et al. (Himmelberg et al., 1999) pointed out that in order to encourage managers to engage in more technological innovation activities, high-tech enterprises should pay more attention to the implementation of executive incentives. The conclusions of Lee et al. (Lee et al., 2005) indicate that different regions and industries have different characteristics, so the role of executive incentives in the technological innovation investment is different. In U.S. high-tech companies, the increase in executive compensation will prompt executives to "outsource" technology and equity incentive will encourage

senior executives to strengthen internal R&D efforts (Xue Y., 2007). Bulan & Sanyal (Bulan, Sanyal, 2011) argue that equity incentives are significantly positively related to the number of patents, and that the number of corporate patents will increase as the sensitivity of stock prices held by executives increases.In China, based on the data of China's GEM listed companies in 2009-2012, Yu Xueran, Hu Yan (Yu Xueran, Hu Yan, 2015) find that short-term remuneration and long-term equity play a certain role in promoting R&D investment.Chen Yan (Chen Yan, 2015) also confirms the view that executive incentives, which are measured in terms of shareholding and compensation, are positively affecting corporate performance. But Du Jian, Zhou Xin and Zeng Shan (Du Jian, Zhou Xin, Zeng Shan, 2012) found that the executive incentive mechanism is not the positive impact and technological innovation R & D investment level.

Du Yong et al. (Du Yong et al., 2014) point out that R&D investment is significant and positively related to a firm's profitability in China. Zhu Naiping et al. (Zhu Naiping et al., 2014) find that there is a significant positive correlation between R&D expenditures in innovation investment and corporate performance, and there is no significant correlation between the number of innovators and firm performance.

In summary, the review of relevant literature in this paper find:Whether it is foreign or domestic scholars, there have been many research results based on executive incentives, innovation investment and corporate performance.These research results show that there is a high probability that innovative R&D investment may have a dual identity, which may be the result of executive incentives or the cause of corporate performance improvement. In previous studies, most researches on executive incentive focused on compensation incentive and equity incentive. Our study will introduce promotion incentive, and take technological innovation as a mediator to explore the impact of executive incentives on GEM listed company's growth.

2 Empirical Predictions

Incentive theory points out that the implementation of effective compensation incentive by enterprise can improve the enthusiasm of managers. Managers will make more efforts to increase their own salaries and make decisions that are conducive to the growth of the company. Due to the separation of ownership and management, senior executives often choose conservative projects and give up high-risk projects in pursuing their own good. As an important incentive method, equity incentive can closely link the management personal interest with the cooperate interest, leading executives to consider the long-term development of the company. With the extension of tenure and the increasingly improvement of management capability, the returns required by executives are no longer limited to the increase in remuneration, but also the pursuit of non-remunerative incentives, especially the pursuit of promotion. When the company is difficult to evaluate the individual performance of the executives, the promotion incentives may have more advantages than the material incentives (Kato and Long, 2011). Based on the above analysis, we propose our first hypothesis:

H1: There is a positive correlation between executive incentives and enterprise growth.

Maslow's hierarchy of needs points out that companies meet executives' compensation demands can make them think their own interests are not threatened, and then their enthusiasm for innovation can be mobilized.Some foreign scholars believe that managers will reduce their investment in technological innovation because of their own interests. In recent years, most scholars in China have found that executive compensation incentive has positive effect on innovation input (Wang Yanni, 2011; Chen Xia, 2017). It probably related to China's policies.China's accounting policy provides that enterprises can capitalize eligible R&D expenses, so cooperate profit will not be significantly reduced. To some extent, this policy, encourages management to increase investment in technological innovation.To obtain high yield, those GEM listed companies with high-growth have strong dependence on future possibilities of investment, and appropriate executive incentives will encourage managers to increase their R&D efforts on high-yield products. So effective executive incentives can have positive impact on innovation investment.Based on the above analysis, we propose our second hypothesis:

H2: Executive incentives have positive effect on corporate innovation investment.

The high-tech companies in GEM listed companies account for a large proportion. For these companies, innovation is an important source of business growth. On the one hand, enterprises can provide differentiated products and services for users through technological innovation, improve new profit margin and gain persistent competitive edge. On the other hand,Enterprises can update equipment, increase production efficiency, reduce manufacture cost, and then obtain price advantage in the market.

Stable income and profit are the key to the sustainable growth of enterprise.Based on the above analysis, we propose our third hypothesis:

H3: Innovation investment is positively associated with enterprise growth.

Most of the companies listed on the GEM are technology-intensive enterprises. Technological innovation is beneficial to the company's long-term vitality. Implementing incentive measures for senior executives will lead managers to increase technological innovation when making decisions. Thus,innovation investment plays an important role in the process of executive incentives affecting corporate growth.Executive incentives can promote innovation investment, while investment in innovation can promote business growth.Based on the above analysis, we propose our fourth hypothesis:

H4: Innovation investment plays an intermediary role in the effect of executive incentives on enterprise growth.

3 Sample and Proxies
3.1 Research sample and data source
Our dataset is obtained from the China Stock Market and Accounting Research Database (CSMAR) developed by Shenzhen GTA Information Technology Company.We selects the initial sample of China's GEM listed companies from 2014 to 2016, including 283 companies after the screening process. We eliminate firms in the financial sector (banks, insurance, and other financial firms), as they are subject to different disclosure requirements in China. ST/PT firms are also excluded because their financial conditions are abnormal. Additionally, the key financial variables are winsorized at the 1st and 99th percentiles to avoid the influence of outliers. And we adapt SPSS22.0 and STATA14.0 to process the data and perform analysis.

3.2 Variable designs
Regarding how to evaluate enterprise growth, domestic and foreign scholars have put forward many different methods, but there is no uniform standard. In order to overcome the limitations of the single indicators, based on the summaries of existing scholars, this paper selects seven indicators that represent the company's financial status and future development potential and to construct a comprehensive evaluation system for corporate growth, including profit growth, growth rate of gross operating income, assets profit margins, return on equity, growth rate of total assets, net profit ratio and BM ratio. SPSS22.0 is used for factor analysis to calculate comprehensive index of corporate growth (*Growth*).

This paper describes the level of executive incentives in terms of compensation incentives (*Pay*), equity incentives (*Sto*) and promotion incentives (*Gap*). Executive compensation incentives (*Pay*) are measured by the natural logarithm of the total remuneration of directors, supervisors, and executives. Higher value indicates the better effect of incentives. To measure equity incentives (*Sto*), we use the percentage of shares held by senior executives in the total number of corporate shares. Following the literatures of Kale et al. (Kale et al., 2009) and Kini et al. (Kini et al., 2012), this paper uses the pay gap between non-chairman executives and the chairman of the board to measure promotion incentive (*Gap*). According to the practice of Wang Yanni (Wang Yanni, 2011), this paper selects the variable of R & D input / revenue of major activities to reflect the intensity of the company's innovation investment (*RD*). Based on previous literature, this paper selects the size of the company (*Size*), asset-liability ratio (*Lev*) and annual (*Year*) as control variables. And the size of the company is described by the natural logarithm of the number of employees at the end of the period.

3.3 Model
To examine the impact of executive incentives on corporate growth, executive incentives are used as independent variables, and cooperate growth is the dependent variable. The following model is established:

$$Growth = \beta_0 + \beta_1 Pay + \beta_2 Sto + \beta_3 Gap + \beta_4 Size + \beta_5 Lev + \beta_6 Dual + \varepsilon \qquad (1)$$

To examine the impact of executive incentives on innovation investment, executive incentives are used as independent variables, and innovation investment is the dependent variable. The following model is established:

$$RD = \beta_0 + \beta_1 Pay + \beta_2 Sto + \beta_3 Gap + \beta_3 Size + \beta_4 Lev + \beta_5 Dual + \varepsilon \qquad (2)$$

To examine the impact of innovation investment on the enterprise growth, innovation investment is used as an independent variable and enterprise growth is a dependent variable. The following model is established:

$$Growth = \beta_0 + \beta_1 RD + \beta_2 Size + \beta_3 Lev + \beta_4 Dual + \varepsilon \qquad (3)$$

In order to examine the moderating role of innovation investment in executive incentives influencing corporate growth, this paper adapts the method of Baron and Kenny (1986) to test the mediating effect and controls the impact of innovation on the basis of model (1). If the mediating effect exists, the influence of executive incentives on enterprise growth should be reduced. In other words, when β_1, β_2 and β_3 are reduced and the correlation is insignificant, the innovation investment is totally mediated. When β_1, β_2 and β_3 are reduced but the correlation is still significant, the innovation investment is partially mediated. Therefore, the following model is established:

$$Growth = \beta_0 + \beta_1 Pay + \beta_2 Sto + \beta_3 Gap + \beta_4 RD + \beta_5 Size + \beta_6 Lev + \beta_7 Dual + \varepsilon \qquad (4)$$

4 Empirical Methodology

Table 1 shows summary statistics of variables. The maximum value of executive compensation incentive indicators is 16.394, the minimum value is 13.924, and the standard deviation is 0.520. It indicates that there are certain differences in executive compensation incentive levels of China's GEM listed companies, which may be due to differences in the number of senior executives. The managers' shareholding ratio gap is large, but the average is 0.346 and the standard deviation is 0.186. This shows that the phenomenon of executive ownership is common and the ratio is relatively high. The average value of promotion incentive indicators is 12.633, the maximum is 14.338, and the minimum is 10.592, indicating that the pay gap of the top management is relatively large. The standard deviation of the investment index for innovation is 0.064, with an average of 0.074. From the data, it can be concluded that the GEM listed companies are highly valued in innovation investment and provide favorable support for the company to maintain a good growth. In addition, the company size and capital structure of different companies are quite different.

Table 1   Summary Statistics of Variables

variable	min	max	mean	sd	N
Growth	-1.014	1.349	-0.003	0.400	846
Pay	13.924	16.394	15.058	0.520	846
Sto	0.002	0.706	0.346	0.186	846
Gap	10.592	14.338	12.633	0.742	846
RD	0.005	0.371	0.074	0.064	846
Size	5.056	9.198	6.934	0.816	846
Lev	0.041	0.684	0.294	0.158	846

In model (1), the coefficient of executive compensation incentives and equity incentive indicators pass the significant test, indicating that greater compensation incentives and higher proportion of senior management shareholdings will lead to better enterprise growth. But the correlation between executive promotion incentives and corporate growth is not significant, indicating that the effect of executive pay gap on the company growth is not obvious. The regression coefficient of firm size is positive and significant at the level of 1%, showing that large firm size can generate economies of scale and bring more funds to the company, which helps the enterprise to increase its competitiveness. The regression coefficient of the asset-liability ratio is negative, and a 1% level of significance test is adopted, indicating that a high proportion of debt structure will limit the long-term development of the company.

Model (2) shows that executive compensation incentives and equity incentives, are significantly positively correlated with innovation investment at the 1% and 10% levels, respectively, indicating that both of them are positively related to innovation investment. That is, by increasing executive compensation incentives and equity incentives, companies can significantly improve the managers' work enthusiasm and promote their decision to increase investment in technological innovation. However, there is no obvious correlation between executive promotion incentives and innovation investment, which is inconsistent with H2. The asset-liability ratio has a significant negative correlation with innovation investment, which means that companies with high proportion of liabilities will have greater financial risks in the future and will reduce investment in innovation. There is a significant positive correlation between firm size and investment in innovation, indicating that large firms are more capable of research and development.

From the results of model (3), the regression coefficient of innovation investment is negative although it passes the significance test, indicating that there is a negative correlation between innovation

investment and company growth. So H3 is not valid. This may be due to the fact that most of the GEM listed companies are not mature enough in scale and have weak anti-risk capabilities, and that the investment in innovation tends to require a large amount of capital.

According to Baron and Kenny's method of verifying the mediating effect, by comparing the model (4) and the model (1), the regression coefficients of executive incentives for enterprise growth decreases, and the significance level of equity incentives drops from 1% to 5%, indicating that innovation investment plays an intermediary role in the effect of executive incentives on corporate growth.

In order to test the reliability of the regression results, this paper uses substitution variables to test the robustness of the above regression results. Scholars usually use two methods to measure innovation investment. One is the ratio of R&D expenditures divided by main business income, the other is the ratio of R&D expenditures divided by total assets. Therefore, this paper uses the latter to reexamine hypotheses. The results are consistent with the regression results above and further support the hypothesis.

Table 2　The Estimation Results of Regression Models

Note: ***, ** and * represent significance at 1%, 5% and 10% level, respectively, with t-values in parentheses.

5 Conclusion

Based on the examination of the relationship between executive incentives, innovation investment, and corporate growth, this paper explores whether innovation investment plays an intermediary role in the relationship between executive incentives and corporate growth. The study shows that: (1) Executive compensation incentives and equity incentives have a significant positive effect on firm growth. Performance appraisal can link corporate interests with executive compensation levels, control the behavior of managers, increase the degree of effort of managers, and urge them to pay attention to the long-term development of the company and thus enhance the growth of the company. (2) Executive compensation incentives and equity incentives have a significant positive impact on corporate innovation investment, that is, the implementation of reasonable compensation incentives and equity incentives for senior executives can help enterprises to carry out technological innovation activities and increase the scale of innovation investment. (3) The investment in innovation has an adverse effect on the growth of the company. In theory, as the investment in innovation increases, the R&D intensity of the enterprise increases, and the production technology and efficiency of the enterprise will increase to some extent, thereby enhancing the enterprise competitiveness. (4) Innovation investment has a partial mediating effect on executive compensation incentives and equity incentives that affect corporate growth. Innovation input is the result of executive incentives, and it is also a factor that affects the growth level of companies.

Executive compensation incentives and equity incentives can guide management to increase investment in innovation, thus affecting the company growth.In view of the above conclusions, China's GEM listed companies should optimize corporate executive compensation structure and improve executive incentives. On the one hand, companies can link executive compensation with company performance, and appropriately increase the percentage of senior management holdings, and make full use of executive incentives to promote corporate growth. On the other hand, companies should combine executive compensation incentives and equity incentives according to their own status quo, set appropriate proportions, maximize incentives for senior executives, and further promote corporate

growth. For innovation investment, companies must strengthen their awareness of innovation, attach importance to innovation investment, and ensure the continuity of innovation activities.

In the future research, further improvements can be made from the following aspects: (1) Since the nature of different industries may influence the research results, the sample size can be increased and a comparative study can be conducted according to industry type. (2) Innovation investment indicators can be comprehensively considered, technical personnel can be included. (3) There is a lag in innovation investment, and future research can combine the lags in the investment in innovation with the regulatory effects to build new models.

Study on Management of Entrepreneurship Education for College Students in China

Bai Yu, He Xinyuan
School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: baiyu_whut@163.com, 21750091@qq.com)

Abstract: College students' entrepreneurship education is one of the important topics in the current society, which is of great significance to the cultivation of innovative talents. This paper analyzes and summarizes the problems existing in the management of entrepreneurship education for Chinese college students, points out the correct orientation of the management of entrepreneurship education for college students in China, and the main contents of the management of entrepreneurship education for college students. Also, it puts forward the concrete countermeasures to improve the management of College Students' entrepreneurship education so as to provide valuable reference for the management of entrepreneurship education for college students in china.
Key words: College student; Entrepreneurship education management; Countermeasure research

1 Introduction

21st century is the age of "innovation". Competition worldwide is focused on the entrepreneurial strength and the level of competition. Innovation and entrepreneurship education has become an engine and power for socio-economic progress. Countries around the world are actively introduced policies to encourage and support innovation and entrepreneurial activities.

Wang et al. (Wang et al., 2005) Summarized the basic function of Chinese college students' entrepreneurship education management: changing employment idea, cultivate pioneering consciousness, cultivate and develop students' entrepreneurial ability, realize the life values of college students.Huang (Huang, 2012) Put forward the main content of Chinese college students' entrepreneurship education management including seven links, that entrepreneurship education mode selection management, risk management, business knowledge and skills reserves and social responsibility management, business incubation service socialization of management, business management, business process management, entrepreneurial culture. Xuan (Xuan, 2015) put the bottleneck of current Chinese college students' entrepreneurship education management summed up as three aspects. The emphasis on entrepreneurship education level is not high including wrong ideological understanding and entrepreneurship education atmosphere is not strong. The teaching system of entrepreneurship education still needs to be improved, including the curriculum system is not complete, lack of specialized teachers, teaching management matching degree is low. The social support for entrepreneurship education is not enough including the society is skeptical about the entrepreneurship of college students, and the support of entrepreneurship education is not enough. And she also put forward the corresponding countermeasures for these problems. To strengthen the management of entrepreneurial education leadership, optimize the teacher team construction, improve the management system, to strengthen the security service system, to set up for entrepreneurial education services department, the monitoring system of entrepreneurship education, to monitor all aspects of factors in the process of entrepreneurship education.

Jiang (Jiang, 2014) pointed out that currently there is no perfect management authority of the entrepreneurship education and entrepreneurial environment and entrepreneurial education management evaluation system is not sound. She suggested to establish specific and efficient coordination mechanism, to optimize the structure; Establishing scientific and reasonable evaluation index system, assessment of entrepreneurship education quality management. Jiang (Jiang, 2015) constructs the evaluation index system of the management of college students' entrepreneurship education According to her previous research, and provides a valuable reference for the future of entrepreneurship education management evaluation.

To sum up, the Chinese college students' entrepreneurship education management has received extensive attention of scholars, at the same time they also points out the bottleneck, the existing research results on the management of college students' entrepreneurship education for future in-depth study and how to promote the entrepreneurship education in colleges and universities management has played a guiding role, and provides a theoretical basis.

However, it should be pointed out that, at present China's government, society and university has

the policy support, capital support, the business place, the respect such as entrepreneurship competition for college students entrepreneurship provides a strong protection. But for entrepreneurship education management of culture idea, thought erroneous zone, such as soft power, the present theoretical system and framework is not perfect, countermeasure research lack of certain depth remains to be strengthened. Therefore, this article will take this as the center of gravity to launch the thorough research.

2 The Correct Positioning of Chinese College Students' Entrepreneurship Education Management

"On deepening the reform of the institutions of higher learning innovation entrepreneurship education implementation opinion" pointed out that we need to fully implement the party's education policy, insist on innovation leading entrepreneurship to create more employment opportunities initiatively to adapt to the economic development of the new normal to promote quality education as the theme. In order to improve the quality of personnel training as the core, we focus on innovative personnel training mechanism to improve the conditions and policy support for the support. To promote the combination of higher education and science and technology, economy and society, to speed up the training of large-scale, innovative spirit, the courage to join the practice of innovative talents team, improve the contribution of higher education to the steady growth of promoting reform and structural adjustment and improve the livelihood of the people. To build an innovative country, implementation, "the two" one hundred goals and the great rejuvenation of the Chinese nation the Chinese dream provide strong intellectual support.

It shows the college students' entrepreneurship education management that one of the main line, two strategic perspectives, the three major changes.

2.1 The main line

Expression of the State Council on innovation and entrepreneurship education for college students and positioning of the show that to entrepreneurship, innovation ability as the core competence of composite type, high-quality personnel training is the basic goal of the innovation and entrepreneurship education of college students, but also to deepen the reform of higher education important task. Therefore, the innovation and entrepreneurship education of college students is quickly integrated into the university personnel training system, and it has become a main line for the orientation and sustainable development of innovation and entrepreneurship education for Chinese students.

2.2 Two strategic perspectives

One is to innovate entrepreneurship education as the starting point, further promote the reform of higher education itself, improve the quality of education and teaching, cultivate talents to promote the economic development and innovation oriented country construction of entrepreneurial, occupation of talent quality bonus heights, and participate in the competition of the international market.

Second, implementation business elite (entrepreneurs: college students start their own businesses and entrepreneurship of inclusive education (post entrepreneurship educators) to promote college students' employment and enhance quality and entrepreneurship of through innovation and entrepreneurship education to improve the students' professional quality and professional ability.

2.3 Three major changes

1) To enhance the level of employment, quality of employment shift from raising the employment rate.

2) Transformation from traditional entrepreneurship education to entrepreneurship education and professional education.

```

└─────────────────────────────────────────────┘
```
Figure 1   The Three Major Changes

3) The realization of the transformation from the cultivation of independent entrepreneurs to the cultivation of post entrepreneurs as the main, supplemented by independent entrepreneurs (Figure 1).

In the next 10 years, the goal of entrepreneurship education management in China is mainly based on post entrepreneurs.

The cultivation of entrepreneurial ability should not be free from the professional courses, but should be based on the professional teaching process of teaching. Taking entrepreneurship education into professional education can lead students to pay more attention to the development and reform of the professional field, so that innovation itself becomes a part of the subject knowledge.

3 The Main Contents of Chinese College Students' Entrepreneurship Education Management

At present, most of the myths about the sense of innovation and the ability to start a business in Chinese society are totally wrong. The sense of creativity and entrepreneurship is neither magic nor mystery. It is related to the ability of the entrepreneur. Entrepreneurship education of college students cannot simply be judged with the number of college students' business entity, or simply use the performance to the success of start-ups to judge; But with the level of the college students' entrepreneurial quality training to judge. Therefore, university students' entrepreneurship education should grasp the main body of uniting the content.

3.1 The cultivation of innovative consciousness

Innovation is necessary to create a talent. The cultivation of innovative consciousness and the starting point of the development to create talents. So, cultivating college students' innovative consciousness, it is a major historical responsibility of modern university (Figure 2).
Figure 2　The Cultivation of Innovation Consciousness

3.2 The cultivation of entrepreneurship consciousness

Entrepreneurship refers to have find or create a new field, we are committed to creating new things to understand (new products, new markets, new production process or raw materials, a new method of organization existing technology), and be able to use various methods to utilize and develop them, and the ability to produce all kinds of new results. In general, entrepreneurial ability mainly includes: opportunity recognition and development capabilities, resource organization and management, strategic planning and management skills, relationship building and operating ability, risk identification and control ability, civil commitment ability. Cultivating college students' entrepreneurship is an important task of modern higher education.

4 Specific Measures to Improve the Management of Chinese College Students' Entrepreneurship Education

The primary problem of college students' entrepreneurship education is the education of values and beliefs, so that the majority of students firmly establish the Chinese dream of achieving the great rejuvenation of the Chinese nation, and the ideal and feelings of the way to make money. To this end, the management of College Students' entrepreneurship education should take the following ways and methods.

4.1 Carry out "the three clear" education of college students' entrepreneurial quality perfection

1) Let college students understand why to start a business.

Entrepreneurship is not to start a business. Business is in dealing with the pursuit of human development, so scientific and technological progress and economic prosperity, people's happiness, and social harmony are very important. Therefore, the essence of the college students' innovative consciousness and ability training is to nurture their attention and enthusiasm to solve the problem of social development, cultivating college students' sense of mission to solve the problem of social development. College students who have the sense of mission to solve the problem of social

development will focus on entrepreneurship. It is basic logic to cultivate college students' innovation consciousness and ability.

2) Let students understand "inputs and unremitting diligently" is the foundation of innovative entrepreneurial success.

When college students have a prosperity for the country and the people fighting feelings, has committed to the sense of mission to solve the problem of social development, as long as there is enough attentively, will be able to find and establish its think must to solve "the most important question. Establishing goals, be about to try (business actually don't need a perfect plan, plan can be as creative practice and gradually improve) is the beginning of an innovative entrepreneurial undertakings, the most important thing is to "adhere to the" next, the so-called "as long as kung fu deep, iron pestle ground into a needle". College students' innovation consciousness and ability cultivation education is to make college students believe that always pay attention to chase, you will change the world!

3) Let students understand "look ahead" is the basic rule of traction startup business sustainable development.

In the startup business, we often encounter questions about "can we succeed?", "can we earn money?". Actually, we don't have to answer them. But you must teach them to learn to "look ahead", "forward" must be filled with challenges. Success is to dare to meet challengers testimonials. Mr. Ma's word makes sense, that "compared with 15 years ago, we are great; but compared 15 years later, we are still a baby."

4.2 Adhere to the entrepreneurial quality education of college students "Five in one, overall progress " mode

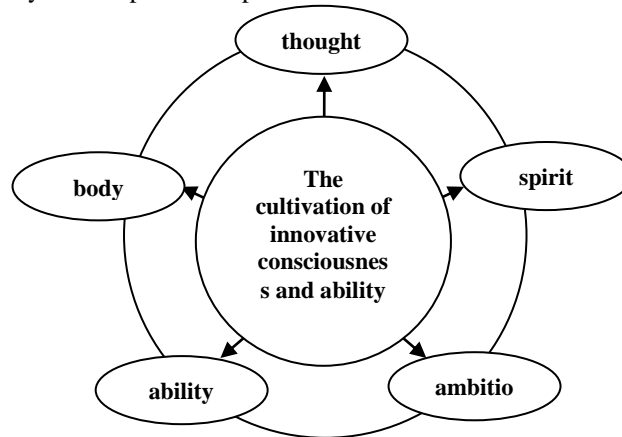
The cultivation of college students' innovation consciousness and ability of entrepreneurship is a full range of systems engineering. The main terms, the cultivation of college students' innovation consciousness and ability of entrepreneurship should be "five in one and coordination" (Figure 3).


Figure 3   The "Five in One, Overall Progress " Model

4.3 Build a "3 and 6 ecosystem environment" of the cultivation of college students' entrepreneurial quality

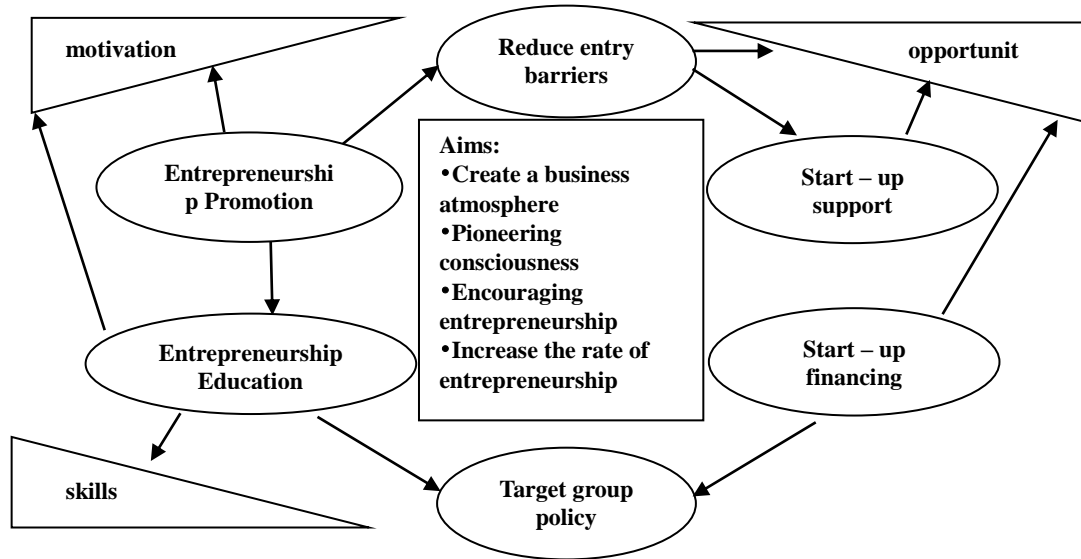
A good entrepreneurial environment is the basic premise for college students' successful entrepreneurship, as good soil can have a good harvest. As the main body of the college students' innovative entrepreneurial leadership in government, enterprises and institutions of the subject of service (especially the financial institutions, the media), the main responsibility of colleges be short of one cannot. Especially in colleges as the main body of responsibility especially the position and role of: education of and colleges have to reform the existing model. Education quality of colleges is not only to let more employers complete the quality education, but also to strengthen college students' consciousness of entrepreneurship, and take entrepreneurial ability training. Colleges must reform the current teaching plan, and take venture education into a compulsory part. Also, self-employment rate of college students has to be included in the evaluation index system of colleges (Figure 4 and Table 1).


Figure 4   3 and 6 Ecosystem Environment

Table 1   The 6 Ecosystem Environment

Entrepreneurship education	Entrepreneurship education at all levels
Entrepreneurship Promotion	Create a culture of entrepreneurship and a positive attitude towards Entrepreneurship
Reduce entry barriers	Reduce the threshold of the enterprise
Start – up support	Support the creation of new enterprises, such as entrepreneurship, incubator, one-stop service
Start – up financing	Provide seed money and loans to new businesses
Target group policy	Special policies for special groups (e.g., young people, women, technology entrepreneurs)

5 Conclusion

College students' entrepreneurship education is the inevitable trend in the development of higher education. The current management of Chinese entrepreneurship education colleges is still at the exploratory introducing stage. There are still a lot of problems. This paper is based on the relevant research of entrepreneurship education management, summary of the current problems and the specific countermeasures of the scholars. We found that currently support for policy, funds, place, etc, have been gradually perfected. But for the understanding of entrepreneurship education in colleges and universities, the concept of entrepreneurship education management such as soft power remains are waited to be promoted. Therefore, this can be taken as a breakthrough, and the following conclusions are obtained:

1) We need to correct positioning for China's college students' entrepreneurship education management.

2) The cultivation of innovative consciousness and ability is the main content of Chinese college students' entrepreneurship education management.

3) The key to solve the current problem is to develop soft culture education, make the ideas into the life of the students

Evaluation for Sustainable Development of the Integration on Internet Crowd Funding and College Student Entrepreneurship

Cai Chun

School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070

(E-mail: 21770646@qq.com)

Abstract: Internet crowdfunding is increasingly becoming an important platform for college students to start their own businesses. There is bound to be a large number of unknown risks for new things. The evaluation of the sustainable development of the integration of internet crowdfunding and college student entrepreneurship is an important part of promoting the long-term development of innovation and entrepreneurship. This article clusters the keywords of the related literatures of Chinese Internet Crowdfunding and college student entrepreneurship, and then taps the core indicators of integrated evaluation. According to distance entropy, the weight of each index is obtained, and then the comprehensive evaluation value is obtained through geometric weighted average. The study finds that the current integration of Internet crowdfunding and college student entrepreneurship focuses on innovation and industry, while having lower expectations for the team, and there are more indicators across teams and innovation.

Key words: Internet crowdfunding; College student entrepreneurship; Clustering; Evaluation

1 Introduction

According to the 2013-2016 college student's employment and entrepreneurship-related data, the proportion of college students who start their own businesses after graduation has increased year by year, which has reached 4.6% by 2016. The investigation and analysis of college student entrepreneurship showed that the difficulty of college students' venture financing is an important factor that restricts the survival of most college students' entrepreneurial projects. The emergence of Internet finance, which complements traditional finance, enriching the financing channels for college students to start their own businesses, and increasing the chances of success of entrepreneurship. With the continuous deepening of the popularization of higher education in China, the employment of college graduates faces a grim situation. With the continuous development of Internet technology, human wisdom has been fully released. Some college students began to use the Internet to start their own businesses. They used the Internet platform in traditional industries to realize industrial upgrading and life values.

The "Thirteenth Five-Year Plan" outline proposes that we must integrate popular entrepreneurship and innovation into all areas of development, encourage multiple entities to develop new technologies, new products, new formats, new models, and create new engines for development. Popular entrepreneurship and innovations require financial innovation to provide risk dispersion and provide financing services. Equity crowdfunding, as a new financing method in the "Internet+" era, is an important form of financial innovation and an organic part of the capital market. It is also an important way to realize innovation and entrepreneurship, effectively link social needs and market resources.

Crowdfunding is a kind of innovation of traditional financing mode,it based on the development of Internet technology. Crowdfunding comes from a combination of concepts such as microfinance (Morduch J, 1999) and crowdsourcing (Brabham D C, 2008). As China's Internet crowdfunding market is still at an exploratory stage, there is no strict screening system. "An individual" in any corner of the world, as an investor or a financier, can participate in this platform. This leads to various risks such as uneven crowdfunding projects, opaque financials and lack of third-party supervision, and examples of failure of the crowdfunding projects are not uncommon. At present, the main problems concerning the integration of Internet crowdfunding and college student entrepreneurship are manifested in inadequate ideological understanding, lack of entrepreneurship education, imperfect entrepreneurial policies, imperfect financial system in science and technology, the weak ability of comprehensive tracking of the project, lack of continuity of funding supply, and more intense information competition, and so on.

Based on the method of co-word clustering, the paper focuses on the integration and development of crowdfunding and youth entrepreneurship, constructs a risk indicator system and indicator condensing model for youth entrepreneurship in the new era, and then determines the weights of various core indicators through distance entropy, and obtains the comprehensive evaluation value through geometric weighted average. From the perspective of the new era of youth entrepreneurship, the

research findings explore the general features and characteristics of youth entrepreneurial risks, and provide some reference for the implementation of China's innovation and entrepreneurship policy and the improving of the country's independent innovation ability. It also provides some ideas for a policy of promoting the healthy development of college student entrepreneurship.

2 Research Status Quo and Current Situation of the Integration of Internet Crowdfunding and College Student Entrepreneurship

Crowdfunding means a financing model that the sponsors of innovative projects publish projects based on online platforms and set the target amount of financing, and use social networks to raise funding for the general public. According to the form of returns, crowdfunding is divided into donation-based, incentive-based (product crowdfunding), loan-based (P2P lending), equity-based, and revenue-sharing. The scope of this paper is equity-based crowdfunding. In this model, the sponsor can obtain certain shares of the sponsor company based on the amount of funding. The typical representative of equity crowdfunding is the United States Angel list platform. There have also been several equity-based crowdfunding platforms in China. Equity crowdfunding refers to publicly micro-equity financing through the Internet. It can provide financing services for small and micro enterprises and entrepreneurs in a more flexible manner. It can meet the investment needs of the middle class and is considered to be the "twin sisters" of "double-invented". It is an important way that researching the current situation of young entrepreneurs who birthed after 1990s and promoting their innovation and entrepreneurship to improve the employment level of the entire society and promote economic and social transformation and upgrading.

At present, the classic models of entrepreneurial risks mainly include entrepreneurial potential theory model(Raab G, Stedham Y, Neuner M, 2005), entrepreneurial tendency evaluation model (Li ñán F,2008), entrepreneurial quotient model (Obschonka M, Silbereisen R K, Schmitt-Rodermund E, 2010), entrepreneurial quality assessment (Souitaris V, Zerbinati S, Al-Laham A, 2007). It also contains qualitative indicators and theories of many scholars for various fields and groups (Douglas E J, Shepherd D A, 2002; Douglas E J, Shepherd D A, 2007).

In 2017, the "China Crowdfunding Platform Rating Report" constructed a set of evaluation system, including 5 first-level indicators of enterprise background, operational capabilities, information disclosure, risk control and compliance, and influence, and 18 second-level indicators, 52 third-level indicators. While the evaluation target sare limited to the crowdfunding platform, and the crowdfunding platform adopts different standards in the review of the youth innovation and entrepreneurship project. On the one hand, it is not conducive to the scientific assess the strength of the youth innovation and entrepreneurship project, and on the other hand, it is not conducive to identifying the risk of youth innovation and entrepreneurship. Youth innovation and entrepreneurship uses internet crowdfunding to obtain various kinds of resource support, but core technology and business model innovation are necessary conditions for crowdfunding projects to continue to retrieving resources. The survival rate of entrepreneurial projects from government-recommended (57.1%) and personal professional interests (58.5%) is lower, while the survival rate of projects with core technologies (67.7%) is higher than that of projects without core technologies (63.6%). In the current Internet innovation and entrepreneurship project, examples of success mainly include new technology products and new farmers. Internet finance is a powerful pusher for the improvement of the current economic situation. However, whether there are hidden dangers behind the current prosperity growth and how risk factors are considered and controlled. What is the attitude of society towards the development of internet finance? At present, some practices are "buy tickets after getting in the car", because the Internet crowdfunding is a new thing, public expect is high, many communities. The government sometimes adopts a "high lift, gently drop" strategy when facing risk issues.

The level of financial development varies greatly in different regions, and Internet finance has broken the boundaries, and whether it has an impact on the coordinated economic development of each region. For one crowdfunding project, one investor, the risks are shared among the individual investors, but whether the total amount of risk which raised by the Internet crowdfunding is reduced. Comparing to the country's financial system, current overall size of Internet crowdfunding is still very small, with two orders of magnitude worse. However, the monitoring of funds raised by Internet crowdfunding is very difficult. Perhaps an immature innovative product can also obtain crowdfunding funds. After A and B rounds of burning money, the responsibility and development of the company immediately falls away.

Although the standardization of internet crowdfunding and the improvement of the supervision

system can certainly provide some risk prevention, the innovation and entrepreneurship of undergraduates are closely linked to risks. It is necessary to form a comprehensive understanding of the risks of innovation and entrepreneurship for undergraduates in the Internet, and then explore effective integration and healthy development of college students' innovation and entrepreneurship.

3 Policy Integrated Sustainable Evaluation Model
3.1 Co-word clustering mining core indicators
Because there are many indicators related to crowdfunding and college student entrepreneurship, the widely-collected indicators are as high as more than 100 indicators. We must achieve the reduction of indicators through factor reduction or clustering to find the core indicators and as a basis for the integration of evaluation indicator system.

Co-word analysis can find out the intimacy between words by counting the number of times a set of keywords (indicators) appear in the same document (CallonM, LawJ,Rip A, 1986),and then to explore the core indicators.

The integration of internet crowdfunding and innovation and entrepreneurship has made entrepreneurs more diversified in personality and quality. The operation of social relations and the improvement of external cooperation capabilities are more critical. Current team building and strategic planning can be supported by more data support and consulting services.According to the latest 210 Chinese documents from 2015 to 2017, extracting the high-frequency keywords and co-word Matrices of youth innovation and entrepreneurship in Internet crowdfunding.

Using the social network analysis tool Gephi, the high-frequency keyword co-word matrix was visualized, as shown in Figure 1. The size of the node characterizes the intermediate nature of the keyword, and the larger the node, the greater the "mediation bridge" role that the keyword plays in the network, and the greater the ability to link different keywords together, the more likely to become a key word for other research themes. The lines between the nodes represent the co-occurrence relationships between the keywords, and the thicker the lines represent the stronger the co-occurrence relationship between the keywords.

Figure 1 shows that team cohesion, market demand, target amount, and number of followers are the basic keywords. These indicators should be used for integrated evaluation, and the number of participants is more intermediary, indicating that the number of participants is a "bridge" for integrated evaluation, and the impact of many indicators needs to be reflected by the number of participants.
Figure 1　High-frequency Keywords Co-word Network

3.2 Entropy weight method determines indicator weight

According to the explanation of the basic principles of information theory, information is a measure of the degree of order of the system, and entropy is a measure of the degree of disorder of the system; if the information entropy of the indicator is smaller, the amount of information provided by the indicator is greater, and the greater the role it is played in comprehensive evaluation, the higher the weight should be.

The distance entropy (Guan Qingyun, Chen Xuelong, Wang Yanzhang, 2015) is the distance between the various units in the system measured by the Euclidean distance,and use the distance ratio to represent the probability of an individual appearing in the system, and the resulting entropy.

It is assumed that there are m sequences in the integrated set. There are p information units in each sequence that describe the sequence values of the integrated objects. The distance entropy of each sequence is calculated as follows:

$$d_{ij} = \sqrt{\sum_{k=1}^{p} (x_{ik} - x_{jk})^2}, \quad i,j=(1,2,\ldots,m) \tag{1}$$

The ratio of the distance to the sum of all distances in the sequence is calculated as the probability of occurrence of each information unit in the information entropy, from which the distance entropy of the sequence is obtained:

$$E_i = -\sum_{i=1}^{p} \frac{d_{ik}}{\sum_{k=1}^{p} d_{ik}} \cdot \ln \frac{d_{ik}}{\sum_{k=1}^{p} d_{ik}} \tag{2}$$

From the extremum of entropy, the closer the probability of occurrence of each information unit is, the greater the value of distance entropy is, the greater the distance entropy E_i, the smaller the discrepancy between each information unit and the optimal value, the closer to the best information unit. Based on the distance entropy, the entropy weight assignment method can be used to calculate the weight of each sequence. The entropy weight assignment method determines the index weights according to the size of the information load of each indicator. The size and quality of the information that the decision maker obtains from the information in the decision-making process and, which greatly influences the accuracy and credibility of the decision. The entropy value can be used to measure the amount of information. The smaller the entropy value is, the greater the variation of the indicator is, and the larger the amount of information is, the greater the role it plays in the decision, and the higher the weight. The entropy value that characterizes the importance of decision of sequence i:

$$e_i = -\frac{1}{\ln m} E_i \tag{3}$$

After normalization, objective weights of sequence iare obtained:

$$w_i = \frac{1 - e_i}{m - \sum_{i=1}^{m} e_i} \tag{4}$$

The determination of w_i is based on objective information. Therefore, it has strong objectivity and uses distance entropy to calculate entropy weight. It can effectively reflect the preferences and quality of information, and provides objective and scientific guarantee for the decision-making integrate information and weight.

3.3 Comprehensive evaluation

Since the integration of internet crowdfunding and college student entrepreneurship is a high-risk attempt, so the use of a weighted geometric average model is more appropriate. The weighted geometric average model is synthesized by multiplication and has a strong sensitivity to score differences between indicators. Once a certain indicator has a zero score, its comprehensive evaluation value is zero.

$$Z_t = y_1^{w_1} \cdot y_2^{w_2} \cdots y_t^{w_s} = \prod_{t=1}^{s} y_t^{w_s} \tag{5}$$

Where y_t is the No.t core indicator, a total of s items.

4 Evaluation of the Integration of Internet Crowdfunding and College Student Entrepreneurship

Crowdfunding is a new type of investment project,because of its individualized and diversified value pursuit, it is more matching with the core concept of the investor's transfer value of the customer.

For investors, the balance between the total value of the project and the total cost determines its final investment behavior.

According to the collected data, the weight of each indicator is calculated by distance entropy (as shown in Table 1). These weights can be used to evaluate the single project expectations, and can also be used to evaluate the development trend of integration of crowdfunding and college students' entrepreneurial.

Table 1   Weights of Core Indicators

No	indicator	weight	No	Indicator	weight
1	Project novelty	0.626659	9	Return rate	0.368507
2	Leader's awareness	0.266945	10	Total financing	0.4567406
3	Transparency of financial information	0.355056	11	Credit investigation	0.265812
4	Information richness	0.265381	12	Followers	0.465734
5	Equity structure	0.170212	13	Target amount	0.269029
6	Team unity	0.466712	14	Awareness of risk	0.365154
7	Market demand	0.664524	15	The number of participants	0.167318
8	Industry sector	0.265552			

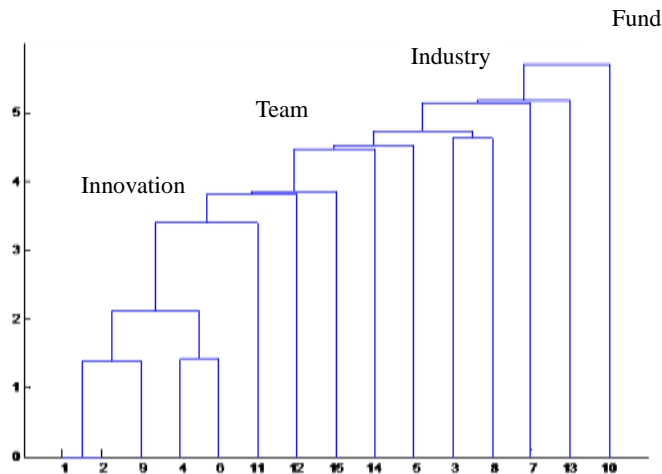
From the above table, it can be seen that the weights of project novelty, transparency of financial information, and credit investigation are not high, while the industry sector, return rate, followers, Equity structure, and Awareness of risk are higher weighted, reflecting that in the integration of crowdfunding and college student entrepreneurship, the public has a high degree of attention to college students' innovation and entrepreneurship, but their actual investment willingness is not high. The investment intentions pay more attention to the evaluation indicators of traditional projects such as industry, market, and returns, while lower to team unity, leader's awareness, and target amount. This shows the public's concern about the entrepreneurial experience of college students.


Figure 2   Co-word Network of High-frequency Keywords

Through hierarchical clustering (as shown in Figure 2), it is found that the topics are divided into four categories at the top of the hierarchy: innovation, team, industry, and fund. Among them, innovation involves project novelty, leader's awareness, information richness, team unity, and response rate of a project. The team involved the most factors, including team unity, information richness, credit investigation, followers, number of participants, awareness of risk, equity structure, and so on. The industry mainly involves the transparency of financial information, market demand, and industry sectors. The funds mainly relate to the total financing and the target amount. It is worth pointing out that due to the level of division, the factors involved in various aspects may exist in cross-cutting situations. For example, there are many crossover factors in terms of innovation and team.

5 Conclusion

Most crowdfunding groups in China are concentrated by 1980s and 1990s. The elites in the youth are actively innovating in all walks of life, stimulating more people to participate in the "national for entrepreneurship". The integration of internet crowdfunding and college student entrepreneurship is still in its infancy, and policy support, education, funding, and innovation are still being explored. Through this research, we can discover the key factors of the integration of internet crowdfunding and college student entrepreneurship through research hot-spots, so as to more reasonably evaluate the sustainability of youth innovation and entrepreneurship. Youth innovation and entrepreneurship in the crowdfunding of the Internet to achieve creative cohesion, capital accumulation, information gathering, from the reputation, financing, market and other aspects of coordinated development, will not let young people daunting entrepreneurial, but have good expectations and unbreakable faith.

Real Earning Management and Firm Investment: Empirical Evidence from Manufacturing Sector of Pakistan

Umair Saeed, Zhang Youtang, Ali Khawaja
School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: umair_444@hotmail.com, 495940524@qq.com, ali_khawaja818@hotmail.com)

Abstract: Stakeholders of the firms use financial statements to make decisions about their investments. The firms are using different earning management techniques to present a financial position of the firm which is not actual. Accrual management (AEM) is popular among policy makers to manage the earnings of the firm but recently more firms were using real earning management (REM) techniques to manage the earnings. REM is change in course of business to show results which are aligned with the management view of the company. It affects negatively on the different indicators of the firm and in the long run its consequences are dangerous. Firm made capital investments to align its goals with the overall strategy of the firm. As firm is involve in REM activities, so it is hypothesis of the study that firm will make more investments than in normal routine of business. The manufacturing sector of Pakistan is taken to study this trend. Panel data set is used to conduct this study for the period 2006 to 2015 from the manufacturing sector of Pakistan. OLS regression is used to check overall effect of REM on firm investment. The result of the study shows that firm which are increasing their sales with discounts to customer are making ineffective capital investments. This article points out to the academicians and policy makers to not only focus their energies only to detect AEM activities in the firm but also investigate REM activities of the firm.
Key words: Real earning management; Firm investments; Agency contract; Manufacturing sector

1 Introduction

The importance of financial reporting quality (FRQ) cannot be denied. The stakeholders of the firm are using these financial statements to decide about the future course of action with the firm. The most important factor to decide for the company is to decide about investment in the projects. The theory suggests that firm should invest in all those projects which have positive NPV and not to invest in those projects which destroy the value for the company (Myers, 1984). The firms with enough financial resources are also faces the dilemma of investing in those projects with suboptimal returns due to managers preference for projects or their self-wealth maximizing objective (Jensen, 1986). As the firm presents its internal situation to external stakeholders of the firm, it creates chances for the firm to invest only on those projects which are beneficial for the firm, so firm investment efficiencybe increased (Biddle et al., 2009). As quality of firm financial reporting quality improves it helps firm in two aspects, one is it reduces the information asymmetry between firm and its stakeholders and secondly it mitigate the risk of unprofitable and nonproductive investment made by the firm (Bushman et al., 2011). Real Earning Management (REM) is the alteration of best practices in the business to report results which benefits the management of the firm for a particular period (Roychowdhury, 2006). The firm level and executive personality characteristics influence the firm managers to engage in REM activities (Cohen and Zarowin, 2008). REM is the activity which can give incentive to the firm for the short period of time but in the long term it is regarded as an activity which damages the value of the firm and engage firm in those sorts of activities which destroy the value of the firm. The management of the firm with the help of REM activities mislead the users of the financial statements of the firm and by this they try to get private benefits for themselves (Wongsunwai, 2013).

This study is to ascertain how REM activities in the context of Pakistan's manufacturing sector effects the quality of investment made by the firm.　This study is unique in the sense that it is the first study in the context of South Asia, where it is questioned how REM is impacting the investment policy of the firm. Earlier this type of studies is conducted in the context of developed countries, but this is first of its kind of study, as per best of our knowledge. South Asia is important region of the world and quite a large number of middle income people lives there. So, this study will contribute in literature in a sense that it will tell readers that if South Asians firms are engaged in REM and if yes how it impacts the overall firm investment performance. The result of the study reveals that firms in Pakistan are doing both kind of REM activities i.e. by increasing sales through sales discounts and by overproduction. The REM through sales discounts induce firms to invest more, on the other hand through overproduction there is no relationship found between these two variables. The data is taken from 2006-2015, for

manufacturing sector companies of Pakistan. The OLS pooled regression is used to get the results for the study. The paper is compiled as follows. In the second section of the study there is Literature review and hypothesis development for the study, in the third section data and research methodology for the study is discussed. Fourth section there is discussion on results and in the last section of the study we present the conclusion of the study.

2 Literature Review and Hypothesis Development

The firms are generally involved in two kinds of earning management techniques i.e. Accrual Earning Management (AEM) and Real Earning Management (REM) (Healy and Palepu, 2001). In case of AEM firms manage their earnings by manipulating their earnings within the scope of Generally Accepted Accounting Principles (GAAP), on the other hand in case of REM firms manage their earnings by managing the actual business operations of the firm like delaying sales, producing more products, giving extra discount to debtors and many other real business activities. As laws become stricter and punishment become severe for management if they involve in earning management activities, so firms start to manage their operational activities to manage their earnings. After 2000 many academicians start focusing their attention on REM activities in the corporate world. Graham et al. (Graham et al.,2005),after his study on REM activities in USA reported that 80% of the executives in USA are willing to involve in such activities where real operating activities of the firm are compromised.

2.1 Real earning management

Roychowdary(Roychowdary, 2006), defined REM as "departure from normal operational practices motivated by managers' desire to mislead at least some stakeholders into believing certain financial reporting goals have been met in normal course of operations." The reasons why executives of the company are engage in REM is due to their personal benefits, to hide the bad performance of the company or to manage their earnings in such a way to lower the variability in earnings (Healy and Wahlen, 1999). The firms which are involve in REM face many economic consequences in future, as the debt holders of the firm require more rate of return on their capital (Zang, 2012). Cohen and Zarowen(Cohen and Zarowen,2008), research on the operating performance of the firm after seasoned equity offering and they provide evidence that future operating performance of the firms which are engage in REM declines more sharply than firms which are involve in AEM.

The firms which are involve in REM face stricter audit by auditors as detection of REM is more difficult and it needs a lot of scrutiny of the firms operational activities (Kim and Park, 2014). The firms after SOX are more involved in REM than in AEM due to pressure from regulators and difficult in detection of REM than AEM (Zang, 2012). The REM is an ongoing process and to manipulate earnings firm manage their activities in any time of the year, on the other hand AEM is mostly done at the end of the year. Chi et al. (Chi et al., 2011), are of the view that as regulations are more strict so executives are reluctant to engage in AEM and they prefer harder to detect earning management activity which is REM. In literature to detect REM three types of proxies are used, which are first used by Roychowdery in his seminal work on REM. These three proxies use sales manipulation, overproduction and discretionary expenses as variable of interest for the detection of real earning management. Arturo et al.(Arturo et al., 2017), study shows that environments where more focus is on individualism and uncertainty avoidance are negatively attracted to the real earning management activities, on the other hand environments where focus is on power distance are positively associated with the REM activities.

2.2 Earning management and firm investment

Modigliani and Miller(Modigliani and Miller,1958), in their seminal work argued that in a frictionless market the determinants of profitability and cashflow position of the firms determine the investment policy of the firms. The markets are not perfect and there are many factors which must be come into consideration for firms to decide about their investment policy. The main purpose of the firms to invest in the project or not to invest is to create value for the firm. The firms which are in the high growth stage need to invest money in the capital intensive projects to support the growth of the firm (Biddle et al., 2009). The firms instead of investing money to create value for the firm due to agency problem and moral hazard invest in value decreasing projects and adverse selection projects (Jensen, 1986, Myers, 1984). The firm investment efficiency improves as firm presents true picture of its activities to its stakeholders. As the quality of financial information improves which implies that firm is not involve in earning management activities results in lowering the information asymmetry which ultimately improves the quality of the investment made by the firm. Financial statements are important source of information for the stakeholders of the firm and the quality of these statements impacts the

quality of financial markets in the economy (Bushman et al., 2011). The quality of financial reports also impacts the cost of capital of the firm and as information asymmetry increases it impacts to raise the cost of capital for the firm. As firm is involve in REM activities it leads firm to invest inefficiently. The more earning management activities companies are involve in they lead them to over-invest (McNichols and Stubben, 2008). As the reporting quality of the firms improves the firm which is engage in underinvestment increase their investment to optimal level, on the other hand firm which is engage in overinvestment reduce their investment to optimal level, which create value for the firm (Chen et al., 2011). The other research in this area gives mixed results where some studies suggest that there is no relationship between accounting information and firm investment level while other result suggests that firm do more investment with earning management activities (Xu et al., 2012, Gilaninia et al., 2012). The studies on the matter point out that earning management activities increases the information asymmetry results in decrease in quality of the investment quality of the firm and it impacts negatively on the firm value.

2.3 Hypothesis for the study

The studies show that as firms are involved in the earning management activities their investment efficiency decreases and firms involves in such investments which are not creating value for the company. The firm is a bound by nexus of contract and if contract is violated than it damages the overall structure of the firm. There is possible information asymmetry between providers of capital and executives of company. This information asymmetry creates mistrust and firms' investment efficiency decreases. Real Earning Management is done by management to hide the true picture of events in firm from different stakeholders of firm and to get personal benefits. This conflict of interest between management and firm shareholders create agency conflict, this conflict leads to investment in such projects which are negative NPV projects or to not invest in positive NPV projects by the management. Financial statements are important source of information for different stakeholders and due to real earning management activities, the quality of financial statements compromised.

Roychowdary (Roychowdary, 2006), shows through his work that as firms are involve in REM, the firms are either involve in overproduction of products or providing cash discounts to increase sales or reduce the discretionary expenses of the firm to increase the firm profit. The firm which are involve in overproduction of products reduces their per unit cost of production which leads to decreases the overall cost of production of the company which ultimately results in increase of company profit for this period. The firm investors and other inside managers of the company are not aware of the company REM gets wrong signal by more production activity of the firm and they anticipate that in future firm prospects are bright. This wrong signal by overproduction activity leads firm to overinvestment in its capital projects. So, for this reason first hypothesis for this study is as follows:

H$_1$: Overproduction activity of the firm leads firm to do overinvestment

The firm managers at the end of financial year show their performance to the shareholders and if they miss some targets than managers may not get bonuses, or it ultimately leads to firing of firm management. REM activity helps management of the firm to show rosy picture of the firm affairs to the shareholders. The management to increase firm's sales gives undue discounts to its customers, which results in increase of sales for the company in this period and shareholders and other inside managers of the firm get a wrong signal that firm sales are improving and to meet these increase sales company must invest in more capital-intensive projects to support this increase in sales. On the other hand, this increase in sales is only artificial one and it cannot be sustainable for long period of time. So, based on this argument, we propose the second hypothesis for the study as follows:

H$_2$: Sales Discounts leads firm to do overinvestment.

3 Research Methodology

The research is conducted in the context of Pakistan. The firms are selected which are listed in the Pakistan Stock Exchange (PSX). Mainly firms are divided into different sectors in PSX, so the firms which lies in financial service sectors are not included into the data for this study. The main reason that financial firms are not included for this study is that the accounting and management style is different of financial firms from the other sectors, so it is not appropriate to include it in the same study. The data is taken from website of PSX for non-financial firms for the period from 2006 to 2015. The data which is not available from PSX website is gathered from websites of firms on website. The data is available for 329 non-financial firms after the final data is collected and final data set is of 218 firms

The variables for the study are divided into three categories i.e. dependent, independent and control

variables. The dependent variable for the study is investment made by the firm. The investment is calculated as investment made by firm in the capital resources. It is calculated as difference between Property Plant and Equipment of last two years scaled by lagged total assets. The regressor for the study is REM. For REM two type of proxies are used by different authors (Jerry et al., 2014). In this study Sales manipulation and overproduction are taken as proxies of REM to test the hypothesis of the study. The sales manipulation is calculated as follows:

$$\frac{CFO_{it}}{A_{it-1}} = \gamma_0 + \gamma_1 \frac{S_{it}}{A_{it-1}} + \gamma_2 \frac{\Delta S_{it}}{A_{it-1}} + \varepsilon \tag{1}$$

Where CFOit is Cashflow from operations lagged by assets. Abnormal CFO are calculated by mean of residuals from the equation 1 which shows that company is involved in activities to do extra sales by means of earning management activities. To measure the overproduction following equation is used.

$$\frac{PROD_{it}}{A_{it-1}} = \beta_0 + \beta_1 \frac{S_{it}}{A_{it-1}} + \beta_2 \frac{\Delta S_{it}}{A_{it-1}} + \varepsilon \tag{2}$$

Where PRODit is sum of COGS of this year plus change in inventory. The residual from this equation will tell us that if firm is involved in overproduction or not. The regression model for the study is as follows.

$$Inv_{i,t+1} = \alpha_0 + \alpha_1 REM_{i,t} + \alpha_2 Q_{i,t} + \alpha_3 Lev_{i,t} + \alpha_4 CFO_{i,t} + \alpha_5 Size_{i,t} + \varepsilon \tag{3}$$

Where Invi, t+1 is the capital investment made by the firm, REMi, t is the Real Earning Management proxies are used in two separate regressions. The other variables are control variables, where Qi, t denotes the Tobin Q to assess the growth opportunities of the firm, Levi, t is to see capital structure of the firm, CFOi, t is the cashflow generated by firm and Sizei, t is measured by taking log of assets which tell us about total size of the firm.

4 Results and Discussion

Table 1 panel 1 of the study presents the descriptive statistics for this study. First, we see the proxy variable for Real Earning management variables and it mean value is near to 0, which shows that average firm in the industry are not involve in real earning management. The intuition tells us that average firm is not involve in the REM, which we can understand by seeing the results of descriptive (Gunny, 2010).

Table 1   Descriptive and Correlation Matrix

Variable	Mean	S Dev	Min	Max	Inv	RM1	RM2	Lev	CFO	Q	Size
Inv	0.78	2.45	0.12	0.95	1						
RM1	0.05	0.66	0.03	0.11	-0.02	1					
RM2	0.03	0.61	0.02	0.08	-0.01	0.96	1				
Lev	0.29	0.25	0.00	0.78	-0.02	0.02	0.03	1			
CFO	0.09	0.67	0.04	0.17	0.09	0.68	0.56	-0.06	1		
Q	2.19	10.15	0.70	5.23	0.13	0.06	-0.04	0.12	0.07	1	
Size	13.47	5.45	7.42	19.29	0.25	0.07	0.04	0.08	0.10	-0.03	1

Inv is capital investment of the firm, RM1 is the proxy for REM through sales discounts, RM2 is REM through over-production, Lev is the debt to asset ratio, CFO is cashflow from operations, Q is the mkt to book value and Size is the size of the firm

The table 1 panel 2 presents result for correlation matrix between the dependent and independent variables for the study. In the study two type of independent variables are used one is main independent variable and others are control variables. The correlation between main independent variables and dependent variable is negative, which suggests that firms which are involve in REM are likely to invest less in the next year. Table 2 presents the results of the OLS regression. To estimate these results two type of REM measures are taken and Model 3 is run separately to get the results. To see how management is involve in REM activities and how its impacts the investment behavior of the firm. In the first scenario, we have run the Cashflow from Operation Model to see how firms which are engage in REM using discounts and incentives to customer conduct their capital expenditure activities. The results which are shown in first column of the table 2 indicates that sales discounts positively impact the investment activity of the firm and firms which are involve in REM using artificial sales discounts invest more. The one reason which we can see from the literature is that the managers which are responsible for investment activities are not aware of the fact that management is involve in earning

management and they invest more in future due to positive signals from the financial reports of the firm. The second proxy of REM which is overproduction activities of the firm, show no significant relationship with the investment activities of the firm. It indicates that firm which are doing REM using over production activity not affect the overall investment performance of the firm. This result can be seen in Column 2 of the result section of the table 2. The model P value shows that model is fit.

Table 2   Regression Result REM Impact on Firm Investment

	Sales Increase	Overproduction
Intercept	-0.288***	-0.161***
RM1	0.034**	
RM2		0.054
Lev	-0.023***	-0.043**
CFO	0.098***	0.076***
Q	0.121	0.051*
Size	0.081*	0.063**
F test (p value)	0.000	0.000
Adj R Square	0.19	0.14

***, **, * indicates significance at 1%, 5% and 10% significance level. All variables are same as defined in Table 1 of the study

Overall these results suggest that firms which are involve in REM activities through sales increasing activities through artificial means are more likely to invest more in the future, as the indication by more sales shows that firm need more resources in future to generate more sales. The other measure of REM i.e. overproduction not show any significant relationship with the investment and from this result we can infer that firms which are doing overproduction are taken as one of event and it has no impact on the future investment of the firm.

5 Conclusion

There is a lot interest among the researchers to check how earning management activities impact the effectiveness of firm overall performance in different aspects. After the accounting scandal of early 21st century, firms are more inclined to do earning management activities through the changes in real activities in the firm rather than doing it through AEM. The real earning management activities of the firm provide asymmetric information to the stakeholders of the company. Because of asymmetric information different stakeholders decide about the firm which is not in the best interest of the shareholders of the firm and firm investment efficiency is not at optimal level. In this study we have taken data from Pakistan manufacturing sector and check if Pakistan manufacturing sector is involved in REM activities and how it impacts the investment performance of the firm. To check REM two measures of REM are calculated in this study and it is ascertained that sales increase artificially through discounts and trade rebates impacts investment of the firm by increasing the investment of the firm in the subsequent period. The reason for more investment are attributed to wrong signal to different stakeholders due to REM activities which induce them to invest more to meet the future sales requirement. This impacts the investment efficiency of the firm and destroy the value of the shareholders of the firm. It is ascertained to the management of the firm to not involve in any kind of REM activities as it not impacts positively on the firm effective performance.

The Research on Evaluation for the Independent Innovation of Biological Industrial Cluster

Wu Na
School of Business, Wuhan Huaxia University of Technology, Wuhan, P.R. China, 430223
(E-mail: haha0629@126.com)

Abstract: Independent innovation is the main source of cluster economic growth, and it is also the driving force of cluster development. Based on the combination of quantitative and qualitative research, theoretical research and empirical research, this paper deeply analyzes dynamic mechanism of the biological industry cluster independent innovation, constructs the evaluation model on this basis. A case study of biolake in Wuhan, through investigating the current situation of independent innovation in this industrial cluster, evaluating the ability of independent innovation by using the principal innovation analysis method, exploring ways to improve the independent innovation capability of industrial clusters from the aspects of establishing innovation alliances, broadening financing channels, improving government functions, forming talents and cultivating leading enterprises, in order to provide theoretical and practical guidance value for the sustainable development of the biological industry cluster.
Key words: Biological industry cluster; Independent innovation; Principal component method; Wuhan biolake

1 Introduction

The biological industry has become a new growth point in the global economy and a strategic demand for industrial development in various countries. It is also a strategic high-tech industry that has been competing for development in various countries in the 21st century. In recent years, China's biological industry clusters have shown rapid development, but compared with foreign mature bio-industry clusters, the overall competitiveness of China's bio-industry clusters is weak. Therefore, it is of great practical significance to study the independent innovation capability of biological industry clusters, in order to promote the sustainable and healthy development of China's biological industry clusters.

Research on industrial cluster innovation at home and abroad have made abundant achievements, and throughout the study of cluster innovation, there were more issues on how to implement the existing industry cluster technology innovation, improve the innovation performance and cluster competitiveness, but issues that related to the ability of independent innovation to promote industrial technology innovation and industrial upgrading were less involved. The existing literature also rarely mentioned the formation mechanism of the autonomous innovation ability of biological industry clusters, and most of them were theoretical framework studies, and there were few relevant empirical analyses. Based on previous studies, this paper deeply analyzes dynamic mechanism of the biological industry cluster independent innovation, constructed the evaluation model on this basis. A case study of biolake in Wuhan, Through the on-the-spot questionnaire survey and interview data of biolake in Wuhan, the impact of various influencing factors on the independent innovation ability of biological industry clusters is quantified, evaluate the independent innovation ability of biolake in Wuhan, on this basis, proposes countermeasures for capacity improvement, in order to provide reference and empirical support for improving the independent innovation theory of industrial cluster.

2 Construction of Evaluation Model for Independent Innovation Ability of Biological Industry Clusters

2.1 Analyses on dynamic mechanism of independent innovation of biological industry cluster

Some scholars have carried out a wealth of research on the dynamic of cluster innovation, representative views are shown as follow:Thomas Brenner (Thomas Brenner, 2001) used to set up a mathematical model to explore the dynamic factors for the evolution of the cluster, He believed that the memory of the cluster in seven power of innovation: cooperation between enterprises, enterprises rely on each other, the local capital market, human capital accumulation, informal communication, public opinion and local policy. Swann et al. (Swann et al., 2002) through the example analysis method, the dynamic mechanism of cluster innovation depicted as including the interaction of dominant enterprises, new enterprises to enter, enterprise incubation increase and climate, infrastructure, and cultural capital of

positive feedback system. Liu Hengjiang and Chen Jixiang described the dynamic mechanism of cluster innovation from two aspects: the excitation power and endogenous power. Motivation mechanism mainly referred to the clusters where the external environment on the cluster control and planning role, such as related policy and regulations, regional brand awareness, competitive environment; in addition to these external factors, there were some influencing factors from inside the cluster, such as complementary to the innovation of the network, the division of labor, for knowledge contribution degree, which was the impact of the fundamental factors of cluster innovation. Gao Daocai et al. (Gao Daocai et al., 2007) argued that the independent innovation dynamic system was composed of external power, peripheral motion and driving force of three subsystems, which outer driving force was the foundation, around power was the guarantee, inner driving force was the soul of innovation activities, at the same time, they restrict and promote each other, jointly promote individuals actively engaged in innovative activities.

Previous studies showed that the independent innovation activities may not be determined by the chance of a single factor, it is determined by the interaction of various factors, such as society, economy, science and technology, culture and policy. This paper argues that the independent innovation activity of the biological industry cluster is affected by the external factors and internal factors, its independent innovation dynamic factors are composed of source dynamic factors and environmental dynamic factors.

2.1.1 Source Dynamic Factors

Source dynamic factors, mainly refers to the existence of the biological industry cluster, which produce core power to biological industry cluster independent innovation, including the independent innovation ability of the enterprise in the biological industry cluster, the benefit pursuit of enterprise or innovation organization in the biological industry cluster, the incentive of innovation agents to generate innovative behavior, and the power of cluster subject collaborative innovation. It directly influences formation and quality of the independent innovation of biological industrial cluster.

2.1.2 Environmental Dynamic Factors

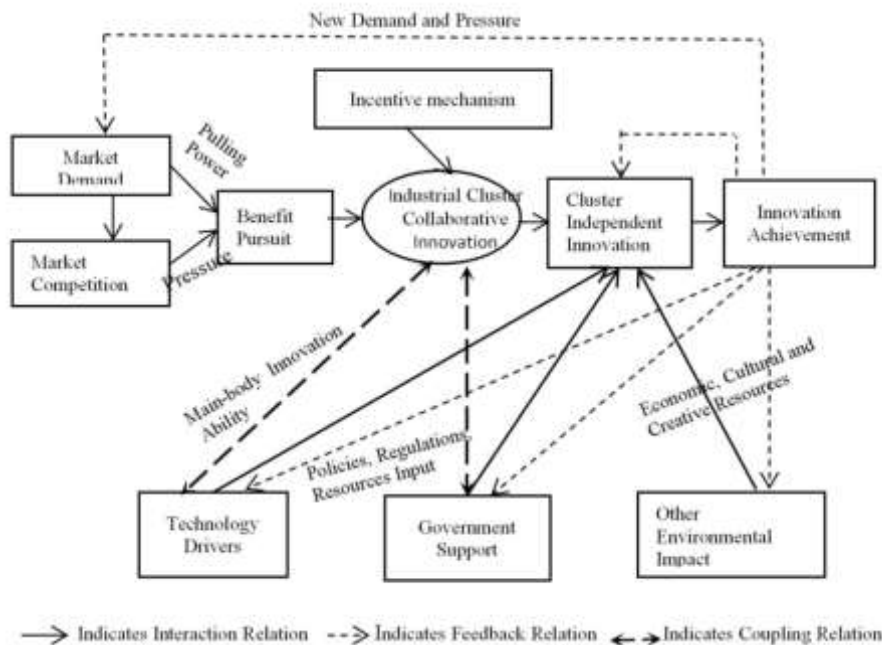
Environmental dynamic factors, refers to the biological industry cluster as a result of external factors on its own initiative to promote the role of innovation, including the pulling power of market demand, the driving force of technology, the pressure of market competition, the government's support, the influence of other environment, For example, the macroeconomic environment, cluster regional innovation resources, social and cultural environment, talent market conditions, financial market conditions, property rights, legal system environment and market economic system, etc..Through the interaction between the biological industry clusters, they have some influence on the formation, operation and duration of the biological industry clusters.


Figure 1   Biological Industry Cluster Independent Innovation Dynamic Mechanism

The dynamic factors and the environmental dynamic factors interact and influence each other;they have a huge driving force for the formation of the independent innovation of biological industry cluster, as shown in figure 1.

2.2 Design index evaluation of independent innovation ability of biological industry clusters

Based on the dynamic mechanism of independent innovation capability of biological industry clusters, and considering the availability of indicator data,the main factors that will influence the ability of independent innovation of biological industry clusters are roughly divided into four aspects: the ability of independent innovation clusters, the ability to invest in clusters of independent innovation, the ability of independent innovation of clusters, and the ability to support independent innovation of clusters.Based on this, the paper regards these four aspects as the first-level indicators for evaluating the independent innovation capability of biological industry clusters.This paper through researching the index system and framework of the evaluation index system of emerging industries and the evaluation of industrial innovation by major institutions in the world at home and abroad, referring to the main indicators of the OECD Biotechnology Key Indicators Analysis (2011 edition) and the main indicators of the comparison of biotechnology competitiveness and the theoretical research results of industrial innovation ability evaluation in Scientific American (2016 edition),combining the characteristics of China's biological industry innovation,The hierarchical system for constructing the evaluation of independent innovation capability of bio-industry clusters is shown in Table 1.

Table 1   Biological Industrial Cluster Independent Innovation Ability Evaluation Index

First-level indicators	Second-level indicators	Third-level indicators
Cluster independent innovation main body ability(A)	Cluster enterprise innovation ability(A_1)	Entrepreneurial innovation (A_{11})
		Technical staff ratio (A_{12})
		Total number of R&D institutions (A_{13})
		Cluster business sales revenue (A_{14})
	Cluster coordination management(A_2)	Cluster coordination management capabilities (A_{21})
Cluster independent innovation investment ability(B)	Cluster R&D funding(B_1)	Science and technology activities as a proportion of sales revenue (B_{11})
		R & D expenditure as a percentage of sales revenue (B_{12})
	Cluster R&D staff input(B_2)	Research and development personnel as a proportion of science and technology personnel (B_{22})
Cluster independent innovation output capacity(C)	Process innovation(C_1)	Process design capability (C_{11})
	Product Innovation(C_2)	Number of new products (C_{21})
		The proportion of new product sales revenue (C_{22})
	Knowledge innovation(C_3)	Number of patent applications for the year (C_{31})
		Number of invention patents of the year (C_{32})
Cluster independent innovation support capability(D)	Government performance(D_1)	Government policy preferences (D_{11})
		Government incentives (D_{12})
		Government investment (D_{13})
	Regional basis(D_2)	Industry-Academy-Study Collaborative Innovation Ability (D_{21})
		Regional Financial Services (D_{22})
		Regional human capital (D_{23})
		Regional Innovation Culture (D_{24})

2.3 Establishment of evaluation model for independent innovation ability of biological industry clusters

At present, there are dozens of comprehensive evaluation methods put forward at home and abroad, but they can be generalized into two categories: subjective empowerment evaluation methods and objective evaluation methods.Considering that there is some uncertainty about the influence of the index on the independent innovation ability of biologicalindustrial clusters, this paper uses principal

component analysis to evaluate the independent innovation ability of biologicalindustrial clusters.

In this paper, SPSS11.5 software is used to analyze the main components of industrial clusters 'independent innovation ability. Its specific operational steps are as follows:

(1) In order to eliminate the influence of the calculation results on dimension and magnitude of the index and ensure the rationality and scientificity of the calculation result, the original data shall be dimensionless processed in the same direction before the analysis, that is, subtracting the mean from the same variable and then dividing Standard deviation, sample mean and sample correlation matrix R = $(Z_{ij})_{pp}$.

$$Z_{ij=} \frac{x_{ij-\bar{x}_j}}{\sqrt{var(x_j)}} \tag{1}$$

$$\bar{x}_j = \frac{1}{n}\sum_{i=1}^n x_{ij} \tag{2}$$

$$var(x_j) = \frac{1}{n-1}\sum_{i=1}^n (x_{ij} - x_j)^2 \tag{3}$$

(2)Finding the eigen values and normalized eigenvectors of R.

Let$|R - \lambda E|$, solve the eigenvalue$\lambda_j$of the correlation matrix R such that$\lambda_1 \geq \lambda_2 \geq \cdots\cdots \geq \lambda_p$, Its corresponding feature vector isα_j, $\alpha_j = (\alpha_{1j}, \alpha_{2j}, \ldots\ldots\alpha_{pj})(j = 1, 2, 3, \ldots\ldots p)$, E is the identity matrix, the principal component$Y_j = \alpha_j \sum_{j=1}^p x_j$.

(3) Calculate the variance contribution rate of each principal component$a_i = \frac{\lambda_i}{p}$ and cumulative contribution rate$\sum a_i$. The variance contribution a_i of the principal component represents the proportion of the variance of the principal component in the total variance, that is, the information of the original n variables obtained by the i-th principal component in the total information；The cumulative contribution rate $\sum a_i$is the proportion of the cumulative amount of information extracted from the previous i principal components in the total information.

(4) Select the number of principal components. Usually, the number m of principal components is taken as the smallest integer that makes the cumulative contribution rate exceeds 75%. These numbers contain most of the information, and the rest of the main components can be discarded. Calculate the score of the main component, and calculate the comprehensive score of each evaluation object. The value obtained by SPSS 11.5 is actually a weighted average of the P principal component scores, which is based on the variance contribution rate of each principal component. The higher the composite score, the stronger the independent innovation ability of the sample. The composite score is positive or negative. If it is positive, it means that it is higher than the average level. If it is 0, it is the average level. If the score value is negative, it means that it is lower than the average level.

3 Research on the Evaluation of Independent Innovation Ability of Industrial Clusters in Wuhan Biolake

This paper selected 20 typical sample companies in Wuhan Biolake and used SPSS11.5 to analyze and calculate the following results:According to the observational variables KMO test and Bartlett test given in Table 3, the Bartlett'sχ^2value is 369.937, the level is significant, and KMO is 0.556> 0.5. It is basically considered that the sampled sample is sufficient, and the principal component analysis can barely be performed.

Table 2　KMO and Bartlett's Test Results

Kaiser-Meyer-Oilskin Test Results		.536

18	0.149	-0.991	-0.918	-0.788	-1.432
19	-0.408	-0.590	-1.574	0.476	-1.351
20	-0.837	1.170	-0.366	-0.757	-0.746

Calculate the cofactor correlation weights:

Table 4   Common Factors Corresponding to the Weight

	λ_1	λ_2	λ_3	λ_4	λ_5	Sum
Quotas	3.534	3.378	3.306	2.991	2.105	15.314
	F_1	F_2	F_3	F_4	F_5	
weights	0.228	0.218	0.214	0.193	0.137	1

Substituting the weight of each principal component into the comprehensive statistical expression, the final evaluation results of the independent innovation of Wuhan Biolake are shown in Table 5.

Table 5   The Final Evaluation Results of the Independent Innovation Capability of Wuhan Biolake

Enterprise	Score	Enterprise	Score	Enterprise	Score	Enterprise	Score
1	0.912418	6	0.185661	11	-0.043570	16	-0.033799

4 Evaluation and Analysis of Independent Innovation Ability of Industrial Clusters in Wuhan Biolake

The above analysis mainly uses the principal component analysis method to conduct an empirical study on the independent innovation capabilities of the 20 scale enterprises selected in Wuhan Biolake. The evaluation results are analyzed as follows:

4.1 The first principal component

The first principal component has the greatest load on the two indicators of cluster enterprise income and R&D institutions. Explain that these two indicators are the factors that play a key role in the rapid promotion of the independent innovation capability of Wuhan Biolake Industrial Clusters. Data show that the optical valley biological city R & D institutions are increasing. Many biopharmaceutical companies have R&D departments in various business divisions of the company, which provides a good technical cradle for the development and innovation of biopharmaceutical technologies, and also lays a good foundation for the original innovation of Wuhan Biolake.

4.2 The second principal component

The second principal component has the largest load on entrepreneurial innovation intentions, the

proportion of science and technology activities as a percentage of sales revenue, and the proportion of research and development activities as a percentage of sales revenue, it shows that the innovation and innovation input plays an important role in the improvement of the independent innovation capability of Wuhan Biolake Industrial Clusters. According to actual data, the average R&D expenditure for Wuhan Biolake is around 25%, which is far more than the R&D expenditures of other pharmaceutical industry clusters in Hubei Province, but compared with the related biopharmaceutical technology clusters abroad, the total investment in R&D of Wuhan Biolake is still insufficient.

4.3 The third principal component

The third principal component has a large load on such factors as cluster coordination ability, regional financial services, government incentive measures, government resources input, and the collaborative innovation capabilities of industry, universities, and research institutes. In terms of government and industry orientation, some aspects are relatively complete and have certain basic conditions for independent innovation and construction. In cooperation with scientific research institutions, Wuhan Biolake companies are located in Wuhan universities and colleges. Many companies are directly derived from universities or scientific research institutions, or are inextricably linked with them. These scientific research institutions are strong. The technological power and advanced technology research it possesses provide solid technical support and guarantees for improving the innovation capability and original innovation of Wuhan Biolake, but the collaborative innovation capability of industry, university, and research has yet to be improved.

4.4 The fourth principal component

The fourth main component is mainly loaded with the number of patent applications in the current year and the number of patent inventions in the current year, which reflects the impact of innovation output on the independent innovation capability of Wuhan Biolake.When Wuhan Biolake was started in 2008, the total industrial income was only over 6 billion yuan. In recent years, the growth rate of major economic indicators of Biological City exceeded 35%, by the end of 2017, industry income has exceeded 300 billion, ranking second in the country.

4.5 The fifth principal component

The fifth principal component reflects the impact of innovative human capital on the independent innovation capability of Wuhan Biolake, which is mainly reflected in regional human capital.Wuhan Biolake has a strong dependence on human technology. According to research results, the qualifications of the R&D department of Wuhan Biolake are basically at or above bachelor degree.

5 Conclusion

Based on studying the dynamic mechanism of independent innovation of biological industry clusters, this paper constructs the evaluation model of independent innovation capability of biological industry clusters, and takes Wuhan Biolake as an example to conduct empirical research.After more than 9 years of development, Wuhan Biolake has made remarkable achievements. However, there are still some problems in the external environment and internal mechanism of cluster independent innovation.Based on the above evaluation results of innovative capabilities, Wuhan Biolake can discuss how to optimize the external environment and internal innovation of biological industry cluster independent innovation from the aspects of establishing an innovation alliance, broadening financing channels, improving government functions, forming talents, and fostering leading enterprises. Mechanism, and how to promote the further improvement of the ability of independent innovation of biological industry clusters.

Monetary Policy, Regional Financial Development and SMEs' Bank Borrowing

Wang Chuanhong
School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: W957253915@163.com)

Abstract: Financing for SMEs has always been a hot topic, based on the regional financial development and property rights, this paper constructs a multiple linear regression model to explore the impact of macro monetary policy on the bank borrowing of SMEs. The result on the sample of small and medium listed companies from 2010 to 2017 shows that in the period of tight monetary policy, the bank borrowing of SMEs will be impacted, and this phenomenon is more obvious in the private SMEs.Besides, this paper also studies the effect of monetary policy transmission from the perspective of regional financial development. The empirical result shows that during the period of tight monetary policy, high financial development will strengthen the monetary policy transmission mechanism.
Key words: SMEs; Bank borrowing; Monetary policy; Regional financial development

1 Introduction

SMEs play a crucial role in promoting the development of the national economy, enhancing regional competitiveness, and improving innovation capabilities. With the development of the financial market, the emergence of new financing methods has enabled SMEs to have more choices when financing, but it still faces the difficulties in financing. The small scale, poor guarantee capability, asymmetric information, and unreasonable funds allocation in the market make it difficult for SMEs to raise funds. In addition, the single financing channel is also one of the key factors. SMEs still rely heavily on traditional financing methods such as bank loans, but bank loans and other methods are deeply influenced by the macro factors. In particular, the monetary policy will impact the SMEs' bank borrowing, thus affecting their financing structures. Therefore, it is of great significance to research the monetary policy and its regional effect on the financing of SMEs.

For a long time, there are endless researches on the financing of SMEs. At the very beginning, people have studied the relationship between SMEs' micro characteristics and their financing behavior. Ciaran Macan (Ciaran Macan, 2010) and Susan Coleman (Susan Coleman, 2011) found that the owner's age, enterprise size, tangible activities, ownership structure and the scale of collateral are the important determinants of bank borrowing for SMEs. There are similar findings in China (Zhang Yingming, 2016). Later, some scholars gradually explore the relationship between macro factors and SMEs' financing. Kinga Mazur (Kinga Mazur, 2007) found that monetary policy will affect SMEs' finance, and the rise in interest rates is not conducive to the financing of SMEs. Robin (Robin, 2016) studied the relationship between the U.S. economic cycle and bank borrowing scale for SMEs, and found that the bank borrowing for SMEs' declined sharply during the period of economic recession. In China, Hu Guohui (Hu Guohui, 2017) also has the same conclusion, the bank borrowing of SMEs is greatly impacted during the economic recession.Later, Rao Pingui (Rao Pingui, 2013) and others began to study the impact of monetary policy, and found that in the period of tight monetary policy, the bank borrowing of SMEs is declined significantly. Zhang Hong's (Zhang Hong, 2013) study shows that in China, there is indeed a regional effect of monetary policy transmission. Xie Jun (Xie Jun, 2014) further studied the influence of regional conduction effects of monetary policy on the enterprise,the development of regional financial markets strengthened the mitigation effect of macro monetary policies on corporate financing constraints.But from the current research, few people have studied the impact of monetary policy on SMEs' financing from the perspective of regional financial development.

Based on the previous research, the following questions will be further discussed: First, whether monetary policy have an effect on bank borrowing for SMEs. Second, will this impact be different due to the nature of property right and regional financial development? The rest of the paper includes the following sections: literature review and hypotheses in section 2, research design is described in section 3, empirical results are presented in section 4, and section 5 is the conclusion.

2 Literature Review and Hypotheses
2.1 Monetary policy, property rights and bank borrowing for SMEs

The influence of monetary policy on micro enterprises is multichannel. First, the tight monetary policy will increase the uncertainty of future information, and this uncertainty will enhance the information asymmetry, which is detrimental to the financing activities of the companies (Khan and Watts, 2009). Secondly, under the tight monetary policy, the supply of money will decline,so the supply of credit will decline significantly.Therefore,the bank borrowing will be greatly impacted (Li Sihai, 2015), and the impact of SMEs will be more grievous (Hu Guohui, 2017). SMEs have always been in a disadvantageous position in financing, especially in bank borrowing.The asymmetric information and management risk make small and medium-sized enterprises face serious credit rationing. The tight policy will aggravate the credit rationing effect, which makes the bank borrowing of SMEs falling significantly.

Private enterprises will be discriminated against in bank borrowing,state-owned enterprises occupied a dominant place in financing (Cull, 2006). On the one hand, state-owned enterprises carry the will of the country and social responsibilities, their network of political relations is vast,and more resources are held in their hands. On the other hand, the government is the invisible guarantor of state-owned enterprises (Zhan Minghua, 2015), making the state-owned enterprises have the advantage of low default risk. In short, the financing environment of state-owned enterprises is obviously better than that of private. Therefore, it is deduced that the impact of private enterprises will be more significant in the period of tight monetary policy.

H1：In the period of tight monetary policy, the ratio of bank borrowing of SMEs will decline, and this phenomenon is more obvious in private enterprises.

2.2 Monetary policy, regional financial development and bank borrowing financing for SMEs

In the transmission of monetary policy, apart from the heterogeneity of enterprises, regional differences may also produce different effects on monetary policy. In China, the economic development level, the financial ecological environment, and the degree of opening to the outside world are not consistent in all regions. All of these may lead to regional effects in monetary policy transmission (Long Haiming 2011). The financial institutions in high financial development areas are not only numerous but and diverse in type, and also have rich financial resources. When monetary policy is tight, the financial institutions, which are at the core of monetary policy transmission, will play a crucial role.Because of the large financial institutions in the developed areas and the large amount of funds, the transmission of monetary policy will be faster and wider, which will make the scale and the cost of financing more flexible to the monetary policy (Li Sihai, 2015), that is, the reduction of credit funds will lead to a rapid increase in the cost of bank borrowing and a decline in the size of financing.Therefore, this paper holds that when monetary policy is tight, the development level of high financial market will strengthen the influence of monetary policy.

H2: There is a regional effect in monetary policy transmission, during the period of tight monetary policy, SMEs in areas with high levels of financial development will be affected more significantly.

3 Research Design

3.1 Sample and data

The sample employed for this study is the listed SMEs from 2010 to 2017, because the listed SMEs have representation to the SMEs, and their data are sound and true. In the data screening process, ST and ST* companies and companies with missing data were excluded, financial firms were also omitted. We finally got 3928 sample data, 491 samples. The financial data are derived from the CSMAR database in China., and the macroeconomic data are derived from the China Economic Net statistics database.

3.2 Variable construction

The main explanatory variable of this paper is monetary policy. There are many ways to define macro-monetary policy, this paper use Lu Zhengfei' method to define monetary policy, calculate the value of M2 growth rate minus the GDP growth rate and minus the CPI growth rate, and define the larger values of 2011,2014, 2016, and 2017 as tightmonetary policy period, and other years as monetary policy loosening period. In this paper, the market index is selected to replace the development level of regional finance for inter-group comparison.In addition, some related variables are controlled in this paper, table 1 shows the meaning of each variable and its calculation method.

3.3 Model

This paper uses fixed effects to test whether those factors have a significant impact on the company's various financing methods. The regression equation is as follows, where Yrepresents the dependent variable, β_0 is a constant, β_i represents a regression coefficient, and ε represents an error term.

$$Y = \beta_0 + \beta_1 MP + \beta_2 IndexFi + \beta_3 Size + \ldots\ldots + \beta_9 Operating + \varepsilon$$

In this paper, we use stata14.0 to test the sample data. In empirical research, it often causes endogenous problems due to missing of variables, so the Hansman test is performed before the regression, and the results show the p value =0, so the original hypothesis H_0 is rejected and the endogenous problem may exist. The fixed effect model is a common method to alleviate the endogenous questions, so the fixed effect model was used for regression analysis.

In addition to the endogeneity problem, multiple collinearity can also affect the regression results. Therefore, this paper uses the variance expansion factor VIF value to test the multiple collinearity of the independent variables. The results show that the VIF of each explanatory variable is less than 2, the maximum value is 1.74, the average value is 1.27, and it shows that there is no multiple collinear between the independent variables.

Table 1   Variable Description

Variable type	Variable name	Description of variable
Dependent variable	Bank borrowing(*Y*)	(short-term loans + long-term loans + non-current liabilities due within one year) / Liabilities
	Monetary Policy (*MP*)	Virtual variable，Take 1 when monetary policy tightens
	Net cash flow from operating activities (*Cashflow*)	Net cash flow from operating/Total assets
Independent variable	Shareholding ratio of the largest shareholder (*Top1*)	The proportion of the largest shareholder in the company
	Size (*Size*)	The logarithm of total assets
	Age (*Age*)	Age of the firm in years at the time of the survey
	Retained profits (*Accumulation*)	Undistributed profits /Total assets
	Tangible assets (*Tangible*)	(Inventory + Fixed Assets) / Total Assets
	Profitability (*Profit*)	ROA

4 Empirical Results

From table 2, it can be seen that the average bank borrowing ratio of SMEs is 13.62%, but the two levels of differentiation are serious, some companies even don't use bank loans for financing. This paper also calculates the equity financing ratio of these samples, the average value of equity financing reached 43%, shows that there do exist equity financing preference among listed SMEs in China. As can be seen from the internal accumulation level, the internal accumulation level of SMEs is generally low, with an average value of only 15%. This also reflects the actual situation of SMEs, that is, the internal funds of SMEs cannot meet the needs of their development. Apart from this, profitability and cash flow, they all meet the characteristics of SMEs.

Table 2   Descriptive Statistics

Variable	Obs	Mean	Std. Dev.	Min	Max
Cashflow	3928	0.0433	0.0750	-0.6702	0.4748
Top1	3928	0.3501	0.1475	0.0415	0.8649
Age	3928	2.3866	0.4890	0.0000	3.5835
Size	3928	21.7350	0.9247	18.5240	25.9794
Tangible	3928	0.3600	0.1637	0.0007	0.9481
Accumulation	3928	0.1508	0.1649	-2.8377	0.7123
Profit	3928	0.0448	0.0840	-2.8341	0.8631
Y	3928	0.1362	0.1391	0.0000	0.8588

The first column in Table 3 is the regression result for the whole sample, the coefficient is 0.00583(Significant at 5% level), indicating that bank borrowingt for SMEs declined significantly during the tightmonetary policy period.

The second and third columns are the results of private and state-owned SMEs. Compared with state-owned enterprises, the bank borrowing ratio of private SMEs has declined 0.00584(significant at the 5% level) during the period of tight monetary policy.

This paper uses the market-oriented development index drawn by Fan Gang to classify the level of regional financial development. It divides the financial development above the average into high-level

groups, and therest of it is divided into low-level groups. The fourth and fifth columns show that the bank borrowing of SMEs with high level of regional financial market development has decreased by 0.0051 (significant at the 5% level), while others has declined 0.00497. In times of tight monetary policy, financial developed regions are more responsive to monetary policy adjustments. The results in Table 3 validate Hypothesis 1 and Hypothesis 2.

Table 3   Impact of Monetary Policy on SMEs' Bank Borrowing Financing

Variable	Total	Private	State-owned	High financial development	Low financial development

5 Conclusion

In sum, the empirical results in this paper shows that: in the period of tight monetary policy, the borrowing financing of SMEs has been impacted, which is more obvious in private enterprises. Meanwhile, the monetary policy transmission has a regional effect, and the high financial development level will strengthen the transmission mechanism. This study enriches the microscopic evidence of monetary policy transmission mechanism, and confirms that the monetary policy transmission has regional effects.

The research of this paper has certain enlightenment meaning for the financing decision of SMEs the tight monetary policy will impact the bank borrowing, so SMEs can make use of trade credit and other ways to raise funds. More importantly, SMEs should improve their financial management system and make reasonable financing plans, choose financial methods according to the changes of macro monetary policy and optimized financing structure continuously. The monetary policy transmission will produce regional effects due to the difference of the financial development level. Therefore, the government should not only focus on the overall situation, but also consider the imbalance between the regions in accordance with the reality of our country, and try to formulate the structural monetary policy and enhance the scientificity of the monetary policy.

Future research can explore the impact of monetary policy on SMEs' financing from different perspectives. This paper uses virtual variables to represent changes in monetary policy, the subsequent

research could also find better standards to measure monetary policy.In addition, the dynamic adjustment of the SMEs' financing structure is also a topic to be further studied.

Abstract: As an experimental area of comprehensive innovation reform, formulating and implementing the planning of the Wuhan Industrial Innovation Center (WIIC) has become a very necessary and urgent task. This paper analyzes the mode for the establishment of global science and technology innovation centers (STIC)under the premise of an in-depth understanding of the development status of industrial innovation centers all over the world. Based on a comparative analysis of Wuhan, Chicago, and Beijing, the modechoice of building WIIC was derived.Simultaneously, based on the phased characteristics of local development, the path of WIIC was analyzed. The conclusions of this paper can be used as a reference for the relevant industrial policies.

Key words: Wuhan industrial innovation center; Science and technology innovation center; Mode selection; Path analysis

1 Introduction

China has entered an era of vigorously promoting comprehensive innovation.The construction of a STIC or industrial innovation center (IIC) has become an important task for all over the country to carry out comprehensive innovation reform experiments.The country has given Wuhan a major mission to take the lead in comprehensively innovating and reforming experiments. Wuhan has foundations, conditions, and advantages to speed up construction.

The IIC refers to cities or regions with regional innovation and extreme nuclear function that are rich in industrial innovation resources, intensive in industrial innovation activities, and clustered by emerging industries.Some scholars used case analysis to study the typical IICs in the world. Cooke (Cooke, 1992) conducted a comparative study of the regional STIC in the Basque Country of Spain, the Emilia-Romagna of Italy, and Wales of the United Kingdom, summing up the successful experiences of the regional STIC.Henton and Held (Henton and Held, 2013) pointed out that Silicon Valley STIC has innovative destruction and evolutionary functions and formed a complete innovation ecosystem.Asheim and Alsaksen (Asheim and Alsaksen, 2002) used Norway as an example to discuss the role of IIC in knowledge transfer and innovation clusters.Research on Asian STICs such as Bangalore (Chaminade and Vang, 2008) and Japan (Fukugawa, 2008) also had important reference value. Some Chinese scholarsenriched the theoretical research on global STICs from a global perspective. Zhong Hua et al. (Zhong Hua et al., 2012) inspected the concept of the global STIC and the distribution pattern of the world theoretically. He took 12 STICs in the world as the research objects and conducted an in-depth analysis of its innovation and development practices.Du Debin and DuanDezhong (Du Debin and Duan Dezhong, 2015) analyzed the spatial distribution pattern of global STIC through data on the 100 most innovative cities in the world and analyzed the decisive factors that affect the growth and development of global STIC.Some China's advanced cities were taken as examples to explore the path of building STICs under China's national conditions. Zhao Hong (Zhao Hong, 2014) and Zhang Yun (Zhang Yun, 2015) discussed the path of Beijing's construction of STIC.Xu Hongqiang(Xu Hongqiang, 2015) proposed the ideas and measures for building a world-class STIC in Shenzhen from the perspective of Shenzhen-Hong Kong innovation economic circle.

It can be seen that the research of IIC has already had relatively rich results and can be used as a reference for the research of this topic.At the same time, it can also be seen that relevant research all over the world mainly focuses on case analysis and empirical analysis. There is a lack of research on the standards and path of IICs.In particular, the publicly published research results concerning WIIC are still missing, and this is exactly what this paper is about.

2 The Mode Choice of Wuhan Industrial Innovation Center
2.1 Global industrial innovation center development mode
Global IICs have the following four modes of development.
2.1.1 Market-driven Mode
Market-driven mode mainly uses market forces to drive the development of IIC. The World STICs represented by Western developed countries represented by New York and London are "natural development modes" that strengthen internationalization factors and market forces.This is a market-driven type.Among them, New York City is the center of the United States economy, finance and trade.In the United States national innovation system, the federal government implements a weak intervention policy.They believe the direction of technological innovation and the numberof capital and manpower that should be determined by the market.
2.1.2Government Guidance Mode
Tokyo STIC is a typical representative of the government guidance mode.From the 1970s onwards, Japan proposed a "technology-based nation" policy, vigorously supported its own R&D of scientific and technological innovations. The government has established a good science and technology innovation environment for Tokyo by formulating scientific and technological innovation plans, supporting the development of emerging industries, providing an external environment that supports innovation, and improving innovation and infrastructure.
2.1.3 Government-market Dual-drive Mode
The government-market dual-drive mode is based on the joint efforts of the government and the market to drive the development of industrial innovation centers.For example, Saxony, Germany, has the strongest economic strength and highest degree of industrialization in the five eastern states.
In the process of industrial innovation, there are three ways in which Saxony government supports companies. The first is financial support. Some start-up high-tech companies can get state government funding support and investment subsidies at the initial stage. The second is research and development support.The state government supports enterprises to cooperate with universities. The third is service support.The government helps the company to enter the market rather than manipulate and control the market.Under the mode of joint government and market, the development of industrial innovation in Saxony, Germany, has made great achievements.
2.1.4 Ecosystem mode
Business-oriented type. As the successful establishment of a high-tech company in Bangalore made it the center of India's information technology, it is known as the "Silicon Valley of Asia".Bangalore has gathered a large number of top global software companies and many top global information industry giants. It has formed a technological innovation system that uses companies as the main body of innovation.

Rely on human resources type.Tel Aviv relies on strong human resources, positioning itself in the global demand for technological innovation market, focusing on the design of innovative products, thereby attracting the participation of global multinational companies' R&D departments and high-end R&D talents, forming a benign urban technological innovation cycle.

University-driven type.Universities play a crucial role in the innovation system of Silicon Valley. They mainly provide talents and knowledge for the various entities in the system, so that knowledge, information and resources can be flowed and transmitted in the network.
2.2 The mode choice of Wuhan industry innovation center
Chicago is the international benchmark for Wuhan to construct IIC. Wuhan once had the reputation of "Oriental Chicago".Both of them are the largest cities in the central region. They have large rivers and large lakes, and they have convenient transportation. They are home to universities and research institutes, both of which were once the steel industry towns and face industrial transformation. In the process of development in Chicago, the government, as a sponsor, establishes a non-governmental organization to widely link resources and operate by market means to ensure the sustainable development of the organization.Chicago upholds the principle that the government does not interfere too much with the business activities in the industry. The government's control measures are mainly directed at market conduct.Wuhan can use Chicago as a benchmark, strengthen government guidance, highlight market leadership, and create an innovative, upgraded version of Eastern Chicago.

Beijing is the domestic benchmark for Wuhan to construct IIC.They are all clustered by universities and scientific research institutes.Beijing, as the capital of China, has inherent advantages in policies and resources. Under the premise of playing a market role, the government supervises and

guides the economic development.Driven by the market and the encouragement of the government, the world's top 500 companies have competed in Beijing and many local innovation and entrepreneurship companies have emerged.Wuhan can use Beijing as a reference to summarize and learn from its experience in building a STIC.

Based on the above benchmarking, Wuhan's construction of an IIC can choose the dual-driven mode of government and market, while focusing on fostering industrial innovation ecosystem.

3 Path Analysis of Wuhan Industrial Innovation Center

The general evolution path of foreign IICs is: capital technology intensive stage, innovation resource accumulation stage, and innovation ecosystem development stage.Some regions can go directly to the second stage across the first stage.Wuhan is at the early stage of the accumulation of innovative resources. The development stage of Wuhan Industrial Innovation Center can be divided into three stages, as shown in Figure 1.
Figure 1   Development Stages of Wuhan Industrial Innovation Center

3.1 Overall layout

Wuhan Industrial Innovation Center locates and layouts according to "2 Valleys 2 Circles 3 Centers". From the perspective of regional layout, it is divided into the core area, the expansion area and the radiation area of the IIC.The core areas of the IIC include the East Lake Independent Innovation Demonstration Zone and Wuhan Economic and Technological Development Zone. The development zone of the IIC includes:Surrounding "Optics Valley" Industrial Innovation Circle, Central University Innovation Circle, Create Valleys Group, Airport Port Economic Development Zone.The radiation area refers to the radiation to the whole city and Wuhan City Circle through the core function of the core area and the expansion of the extended area.

From the industrial layout point of view, focus on the construction of three major industrial innovation centers. Build a new generation of Information Technology IndustrialInnovation Base (Center) and become a global leader in next-generation information technology. Build a Life and Health IndustrialBase (Center) and become a leader in domestic life and health industrial technology.Build an Intelligent Manufacturing Industrial Innovation Base (Center) and become a leader in domestic intelligent manufacturing industrial innovation.

3.2 Two valleys

3.2.1 Optics Valley

Completed international standards and patent-intensive areas.In 2020, we will strive to create more than 100 international standards, and the number of PCT international patents will strive to exceed 1,000 and enter the first domestic phalanx.

Create a world-leading corporate headquarters base. In 2020, the world's top 500 companies and world leaders in the establishment of R&D headquarters, sales headquarters, and manufacturing headquarters in "Optics Valley" will strive to reach 1,000.

Cultivate the international union of photoelectric information industry.To promote the international development of Optics Valley's optoelectronic information industry alliance and attract optoelectronic information companies with global influence.

3.2.2 Create Valley

Build Offshore Innovation and Entrepreneurship Center (OIEC) for overseas scientific and technological talents.With the approval of the Wuhan Free Trade Zone as an opportunity, accelerate the pilot work of Wuhan OIEC in the Free Trade Zone.

Create a diversified International Entrepreneurship Base (IEB).To establish an IEB that integrates the students' entrepreneurial park, technology business incubator, creative space, and innovation and entrepreneurship center.

Enhancing the World Image of " China Create Valley " in Wuhan.Strengthen cooperation with

Wuhan Optics Valley and Silicon Valley, Wuhan and Chicago.Further explore cooperation with world-class parks to build R&D centers and cooperation parks, set up mutual bases, and set up joint venture funds.

3.3 Two circles

3.3.1 Surrounding "Optics Valley" Industrial Innovation Circle

Build the Surrounding Optics Valley "optoelectronic plus" industry innovation platform.Photoelectron as a link and carrier, through the optical perception, optical interconnection, optical computing, optical display, optical energy and other means to achieve interconnection of all things, and promote the optoelectronic industry and other industries cross-border integration development.

Cultivate the Optoelectronic derivatives and supporting industrial belt surrounding Optics Valley.Focusing on the upstream and downstream industrial chain of optical fiber cables, optoelectronic devices, lasers, communication systems, software, and other industrial leading enterprises, create a creative space for small and micro enterprises in related industries.

To create a "one-core, multi-polar" bio-industrial innovation circle surrounding Optics Valley.It is centered on the "Wuhan National Biological Industry Base" in East Lake Hi-tech Zone, creating the core area of the entire industrial chain of the life and health industry.

3.3.2 Central University Innovative Economy Circle

The construction of WIIC needs to give full play to the advantages of science and education resources and the advantages of knowledge innovation in institutions of higher learning in China, and promote innovation at the source,which is shown in Table 1.

Table 1   Central University Innovative Economy Circle

Central University Innovative Economy Circle	Carrier	Industry
Wuhan University Huazhong University of Science and Technology Central China Normal University	Along Luoyu Road Innovation Economic Circle	722 Technology Startup Incubator, Beacon Innovation Valley	Information Technology, Cultural Creativity Robots, 3D Printing, High-end R&D Life and health Cultural Creativity
Wuhan University of Technology		WHUT Wisdom Valley, Intelligent Transportation Technology Innovation Base, Information Industry Base, etc.	New Materials, Transportation, Information Technology, Cultural Creativity
Huazhong Agricultural University South-central University for Nationalities Wuhan Textile University	Along South Lake Innovation Economic Circle	Integration of Wisdom Valley Internet Industrial Park, Wuhan Creative Place, South Lake Creative Industrial Park	Modern Agriculture Cultural Innovation
Huangjia Lake University Town		Qingling Ecological Science Park, Hubei University of Chinese Medicine Health Industry Park	High-end Industry and R&D, Life and Health Industry
China University of Geosciences		China Jewelry Valley	Jewelry, Finance

3.4 Three centers

3.4.1 New Generation of Information Technology Industrial Innovation Center

Focusing on the development direction of the mobile Internet and Internet of Things industry, lay out a complete industrial chain and innovation chain for optoelectronics, optical displays, integrated circuits, geospatial information, and intelligent terminals. Create an innovation center for optoelectronic manufacturing and build a new generation of information technology industrial innovation bases.

3.4.2 National First-class Life and Health Industrial Innovation Center

Focusing on drugs, medical devices and health services targeting major diseases, deploy biomedical and medical devices, precision medical services and services, health care and bio-agriculture industrialization projects and innovative institutions. Develop new business forms for biological services

and health services and build a domestic first-class life and health industry innovation base.
3.4.3 National Important Intelligent Manufacturing Industrial Innovation Center
Focusing on the innovative direction of deep integration of new generation information technology and manufacturing technology, we will deploy industrial projects and innovative carriers such as sensors, industrial software and high-end CNC machine tools, robots, marine engineering equipment, and aerospace equipment, and build an important intelligent manufacturing IIC in China.

4 Conclusion

Based on the academic achievements and practical experience of the predecessors, this paper summarizes the four development modes of the global industrial innovation centers, including market-driven mode, government guidance mode, government-market dual-drive mode and ecosystem mode. According to the comparative analysis of Wuhan, Chicago and Beijing, the development model suitable for Wuhan to construct an industrial innovation center is selected, namely the dual-driven mode of government and market, while also focusing on fostering industrial innovation ecosystems.

According to the experience of developing industrial innovation centers in other regions, the path of Wuhan Industrial Innovation Center was obtained, namely the "2 Valleys 2 Circles 3 Centers" path. Including Optics Valley, Create Valley, Surrounding "Optics Valley" Industrial Innovation Circle, Central University Innovative Economy Circle, New Generation of Information Technology Industrial Innovation Center, National First-class Life and Health Industrial Innovation Center, National Important Intelligent Manufacturing Industrial Innovation Center.This paper also gives suggestions and measures to achieve this overall layout.

In the future, Wuhan will strive to basically establish an industrial innovation center around the overall layout of the "2 Valleys 2 Circles 3 Centers" path in 2025. And in 2035, the goal of fully building Wuhan Industrial Innovation Center with international influence will hopefully be completed.

Influence Factor Analysis of Industrial Science and Technology Innovation Alliance Based on System Dynamics

Yan Jingdong, Liu Xiangmiao, Fan Youheng
School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: yjdong02@163.com, 1140761679@qq.com, 962632494@qq.com)

Abstract: As a new organization form of industry-university-research collaborative innovation, the industrial science and technology innovation alliance is an important carrier to implement the national innovation-driven strategy and build China's technological innovation system.Based on the current situation of the industrial technology innovation alliance development, this paper discusses the causality of the industrial science and technology innovation alliance development, uses system dynamics to simulate the relationship among enterprises, government, and University-Research party, draws conclusions and makes suggestions for the development of China's industrial technology innovation alliance.
Key words: Influence factor; Industrial science and technology innovation alliance; System dynamics; Governmentfunding; University-research party

1 Introduction

December 2006, China's Ministry of Science and Technology, China's Ministry of Finance, together with other 3 departments, carried out the pilot work of the industrial science and technology innovation alliance, which aims to ensure legally-binding contracts, andform a collaborative technological cooperation between joint development, complementary advantages, benefit sharing, and risk sharing.

Recent years, Domestic and foreign researches have focused on the connotation, operation mode, mechanism, risk sharing, and performance researchs. Industrial science and technology alliance have been divided into equity or non-equity alliances(Rothaermel,2001).Enterprises in alliance face more risks than independent companies in pursuing the maximization of their own interests(Das,2007).There are types of conflict influencing factors in the alliance,which means that governments, universities, and scientific research institutions must establish a collaborative innovation network based on profit sharing(Li Feng,2014). Performance evaluation indicator systems has been established to analyze alliance performance(Pan Donghua,2013).From the perspective of subjective utility, a performance evaluation index system based on the alliance operation process has been constructed (Tan Jianwei, 2017).

There are few studies from the perspective of system dynamics, however the use of system theory to analyze the structure and operating mechanism of the coalition is of great significance to the stability of the industrial science and technology innovation alliance.

2 Development Status of China's Industrial Science and Technology Innovation Alliance

Industry technology innovation alliance pilot work contact group is supportedbyChina's ministry of Science and Technology, in order to deepen the union pilot work, promote the communication between the union organization, communication and cooperation.This article analyzes the development status of China's industrial science and technology innovation alliance based ontheregistered 150 pilot alliances.

From the perspective of geographical distribution, the industrial science and technology innovation alliance has basically covered the whole country.According to the location of the sponsor or governing unit of the coalition, 150 pilot alliances were classified, of which 68 were Beijing pilot coalitions, accounting for 45.33% of the total; followed by Shandong,Hubei and Shanghai(Figure 1).
Figure 1   Regional Distributionof Pilot Alliances

From the perspective of technical field, the alliances cover agriculture, forestry, animal husbandry and fishery,etc. among which there are 33 alliances for agriculture, forestry, animal husbandry and fishery industries, accounting for 22.00% of the total;23 biotechnology and pharmaceutical technology industry science and technology innovation alliances, accounting for 15.33% of the total.
Figure 2　Industry Distribution of Pilot Alliances

Table 1　Activity of Pilot Alliances in 2014-2017

	Activity	2014	2015	2016	2017
Higher	Quantity	36	56	29	24
	Percentage of the evaluated alliance (%)	31.03%	44.80%	29.00%	23.76%
	Percentage of total (%)	24.66%	38.36%	19.86%	16.44%
High	Quantity	37	34	23	22
	Percentage of the evaluated alliance (%)	31.89%	27.20%	23.00%	21.78%
	Percentage of total (%)	25.34%	23.29%	15.75%	15.07%
General	Quantity	29	18	30	35
	Percentage of the evaluated alliance (%)	25.00%	14.00%	30.00%	34.65%
	Percentage of total (%)	19.86%	12.33%	20.54%	23.97%
Poor	Quantity	14	17	18	20
	Percentage of the evaluated alliance (%)	12.07%	13.60%	18.00%	19.80%
	Percentage of total (%)	9.59%	11.64%	12.32%	13.70%

Data source: China association for industrial science and technology innovation

From 2015 to 2018, The secretariat of the China Industry Technology Innovation Alliance Association continued to organize the activity evaluation work and evaluated the pilot allianceswithcomplete information. The evaluation indicators include 3 first-level indicators (establishment and operation of alliance organizations, collaborative innovation activities of the alliance, effectiveness of the alliance in stimulating the development of the industry)and 20 second-level indicators. The evaluation results are shown in Table 1.

Industrial Science and Technology Innovation Alliance has covered most of China and involves a diversified technical field. China's industrial technology innovation alliance has achieved a certain degree of development, but there are still some problems: (1) The alliancesare unevenly distributed. The Beijing pilot coalition accounts for 45.33% of the total, while Liaoning, Qinghai, Shanxi, and Xinjiang have only one pilot coalition in underdeveloped regions. (2) The quality of the development of China's industrial science and technology innovation alliances is not high. The participation rate of activity evaluation is about 75%, indicating that some pilot coalitions areneglected; the proportion of higher and high activity was only about 50%, and it showed a further downward trend.

3 Model Construction

System dynamics gradually reveals causal relationships between system elements through the establishment and control of mathematical models.The constituent elements of the industrial technology innovation alliance, a complex relationship between enterprises, academics and the government, meet the structural requirements of dissipative nature. Therefore, the use of system dynamics to simulate the industrial science and technology innovation alliance can reveal the interest relationship in the alliance (Liu Linzhou, 2012). System structure theory has been used to analyze the operating mechanism of the industrial science and technology innovation alliance system (Xiong Li, 2017). Internal variables such

as trust, speculative behavior, will lead to greater volatility (Yuan Yijun, 2013), IT capabilities affect the performance of the alliance as well (Yang Chen, 2014).

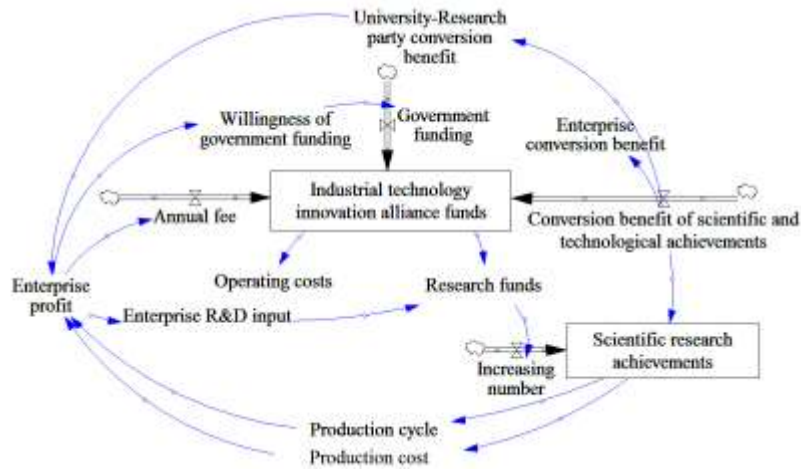
This paper summarizes the industrial technology innovation alliance as three main elements: enterprises, university-research party, andgovernment, then summarizes the relationships among them:


Figure 3   Inventory Flow Chart of the Industrial Science and Technology Innovation Alliance

(1) Relationship between enterprises and university-research party:1)Enterprises need to pay the annual fee for joining regularly, and the annual fee removes the remaining part of operating expenses as research funds.2) The increase of enterprise profits will increase the investment of enterprise R&D funds, some of which will become alliance research funds through the establishment of alliance projects.3)The investment of scientific research funds will increase the achievements of university-research party.4)With the increase of the achievements of scientific research institutions and the progress of production technology, the production cycle of enterprises' products is shortened and the cost of products is reduced, which can further increase the profits of enterprises.

(2) Relationship between enterprises and government:1) Government can provide policy support, funding, and coordination of the internal relations of industrial technology innovation alliances for enterprises, which will help improve the transformation of the results of enterprises and alliances and increase corporate profits. 2) Increasing in corporate profits will bring vitality to the development of the industry, which will increase the government's willingness.

(3) Relationship between government and university-research party: Government's increasing willingness to fund the alliance will help university-research party obtain more research funds and further enhance the ability of university-research party to transform their achievements. The increasing in research capabilities of the Alliance will also help increase government funding.

To sum up and improve the above three causal relationships, the system dynamics inventory flow among three elements of the industrial technology innovation alliance can be obtained (Figure 3).

The industrial science and technology innovation alliance involves many subjects, and the interest relationship is also complicated. This article will focus on examining the impact of the role of government and university-research partyplay in the alliance on companies. Assuming that product demand equals output, corporate profits can be expressed as (1):

$$W = d\frac{p-c}{R} \cdot a + I \tag{1}$$

$$S = S_0 + \beta\frac{P-P0}{P0} + \gamma e^{\delta\frac{m0}{m}} \tag{2}$$

where W is the profit of the company; p is the price of the product; c is the production cost of the product; d is the demand for the product; a is the annual fee paid by the company; I is the income of the company's achievements.S is usedto analyze the role of government funding for the coalition, $0 \le S \le 1$.Government has a basic investment intention $S_0$for industrial technology innovation alliances, $0 \le S_0 \le 1$.

Assuming that the government funding intention has a positive correlation with corporate profits and the number of scholars' research achievements. The specific relationship is shown in equation (2). Among them, α, β and γ are parameters that reflect the impact of corporate profits and academic achievements on government funding intentions; P is corporate profits, P_0 is the initial profit of the company; $\delta < 0$ is the parameter; m is the number of achievements of the research party, and m_0 is the

number of initial results of university-research party.

The impact of the research institute of the Industrial Science and Technology Innovation Institute on the company's performance is to increase the profit of the company by reducing the production cost and production cycle. The specific relationship is shown in equations (3) and (4):

$$c=0.5+\lambda_1\frac{b1}{m^{\theta_1}} \tag{3}$$

$$r=(0.5+\lambda_2\frac{b2}{m^{\theta_2}})*r_0 \tag{4}$$

where r is the production cycle, r_0 is the initial value of the production cycle, assuming that the production cost and production cycle are reduced to at most 50%; λ_1, λ_2 are constants, $0<\lambda_1<1$、$0<\lambda_2<1$; b_1、b_2 are parameters, indicating the degree of influence of academic research results on product cost and production cycle, the larger the value, the higher the degree of impact.

4 Parameter Setting and Simulation Analysis

This paper simulates the corporate profits and discusses the influence of government funding intentions and university-research party achievements on the development of enterprises in the industrial technology innovation alliance. Due to the limited data acquisition, we extract the government funding intention as a government factor; extracts the impact of the academic research results on product cost and production cycle b_1, b_2 as the academic research influencing factors, and formulates four simulation programs, as shown in Table 2.

Table 2   Parameter Scheme

	Government funding intention (S)	Quality	Quality of research results	
			Impaction production cost (b_1)	Impact on production cycle (b_2)
Plan 1	0.7	high	2	2
Plan 2	0.3	high	2	2
Plan 3	0.7	low	8	8
Plan 4	0.3	low	8	8

Through simulation calculations, the profitability of the company under the four plans can be obtained in Figure 4.
Figure 4   Profit Graph of Four Plans

From the above figure, we can draw following four conclusions:

(1) The four schemes all make contribution to the improvement of corporate profits, indicating that the government grants and the university-research party achievements are indeed positively related to the growth of corporate profits.

(2) The profit growth rate of the four schemes in the initial period is greater in the later period, which shows that the initial impact of the government subsidy and the quality of the university-research party on the industrial technology innovation alliance enterprises is greater than the later.

(3) Comparing the profits of Plan1 and Plan 2，the enterprise profits of Plan3 and Plan4，when the quality of university-research party achievements is at the same level, the profits of enterprises with high government-funded willingness are higher.

(4) The profits of Plan1 andPlan2 after the simulation are higher than those of Plan3 and Plan4, that is, the effect of the quality of academic achievements on the profits of the enterprises is higher than the effect of the government subsidies on the profits of the enterprise.

5 Conclusion

In response to the conclusions of this paper, the following recommendactions are proposed for the development of China's industrial science and technology innovation alliance:

(1) Improve the initial support of the alliance. The government subsidy has a positive effect on the industrial science and technology innovation alliance. Since this kind of benefit is a diminishing marginal return, the government should pay more attention to the new industrial technology innovation alliances, increase financial support, guide scientific research plans,play a coordinating role for new alliances, andappropriately reduce financial support for relatively stable and relatively mature alliances.

(2) Absorb high-qualityuniversity-research parties. From the conclusion of this paper, we can see that the quality of research results is more obvious than the government's funding, and it has a greater role in promoting the development of industrial science and technology innovation alliances. Therefore, the alliance should actively seek cooperation with academic research institutions, especially to attract high-level institutions of higher learning, scientific research institutions, to reduce the dependence on government support funds.

(3) Improve the ability of independent innovation of enterprises. Government funding and university-research party can increase corporate profits to a certain extent, but this effect has a law of diminishing marginalization. Alliance enterprises cannot rely too much on other members of the alliance. They should increase R&D funding, attract high-tech talent, seek cooperation with academic research institutions, cultivate and reserve talents, enhance their own scientific research capabilities and independent innovation capabilities, and enhance their core competitiveness.

Research on the Improvement of Industrial Innovation Environment in Wuhan

Xie Ruiting[1,2]
1 School of Foreign Languages, Hubei University, Wuhan, P.R.China, 430062
2 Manufacturing Industry Development Research Center on Wuhan City Circle, Jianghan University, Wuhan, P.R.China, 430056
(E-mail: sherryting0716@ qq.com)

Abstract: Nowadays, innovation has become a driving force behind the national economic development and an effective way to promote social advancement. This paper probes into the three factors in industrial innovation environment, namely policy environment, industry environment and talent environment. Some tentative suggestionsfor improvingthe industrial innovation environment in Wuhan are also put forward in the paper. It is pointed out that relevant policies should be introduced to emphasize and cultivate the subject of industrial innovation and retaining talents should be the top priority in innovation environment.
Key words: Improvement; Industrial innovation environment; Wuhan; Suggestions

1 Introduction

Environment for innovation plays a vital role in carrying out innovative activities. A favorable innovation environment can improve innovation openness degree(Gao Wei, 2016) and provide the innovators with more opportunities (Li Jun & Chen Hansong, 2010). Till now there are a great number of researches on the topic of innovation environment all over the world. Alberto Hurtado (Alberto Hurtado, 2010) examined the internal environment of innovation in the organization by conducting a qualitative research in five different companies. Erickson (Erickson,1996) discussed the influence of national innovation systems on management behavior and he pointed out that national innovation environment by its nature may vary from country to country. Xu Tingting and Wu Hecheng (Xu Tingting and Wu Hecheng,2013) built an evaluation system to analyze the regional innovation environment in Jiangsu province with a result showing distinct differences in innovation environment in different parts of the province. Zhang Zongyi and Zhang Ying (Zhang Zongyi and Zhang Ying,2008) used Data Envelopment Analysis (DEA) to analyze the impact of innovation environment on the efficiency of regional innovation, and the result of the research indicated the impact was a significant one. Based on an empirical study on the relationship between innovation environment and performance, Zhou Jingkun and Duan Zhongxian (Zhou Jingkun and Duan Zhongxian,2013) found out that the high level of entrepreneurship would have a positive effect on innovation environment. To summarize, there are abundant studies on innovation environment, but till now most of the researches center on the innovation environment in first-tier cities or in technical companies. Besides, practical and detailed measures to improve innovation environment are often not provided in the current researches. In this paper, essential factors of innovation environment are discussed, a comparison between the innovation environment in Wuhan and that in Beijing is carried out and some tentative suggestions on the improvement of innovation environment in Wuhan are put forward.

2 The Status Quo of Industrial Innovation Environment in Wuhan

According to the research conducted by Tsinghua university TusPark research institute for innovation, policy environment, industry environment, talent environment, R&D environment, financial environment and intermediary market environment are 6 central elements in evaluating innovation and entrepreneurial environment. In this paper, the status quo of industrial innovation environment in Wuhan is approached from 3 different angles (out of the 6 central elements mentioned above), namely policy environment, industry environment and talent environment. Furthermore, a brief comparison of the industrial innovation environment in Wuhan and that in Beijing is made to identify gaps and provide ideas for further improvements.

Beijing, the center for cultural and business activities, is also one of the leading cities of innovation. Electronic information, bio-medicine, artificial intelligence and R&D are regarded as industries with local advantages. In Beijing, there are 92 universities and colleges with 235318 graduates in the year of 2017. There are 12388 high-tech enterprises in Beijing in 2017, accounting for nearly 20% of all the

high-tech enterprises national wide. There are about 200 maker spaces in the city and more than 150 business incubators and science parks.

In Beijing, the innovation policies are rather loose in order to foster innovation and entrepreneurship in industries with competitive advantages. The local fiscal and taxation policies are favorable to innovative business, which contributes a lot to the forming of a cluster of high-tech enterprises in Beijng. The Zhongguancun National Demonstration Zone, with a history dates back to the early 1980s, is a very good example of innovation business in Beijing. Recently innovation funds are established for innovation projects, providing discounted interest rates and equity investment to create a better innovation environment and ease financial pressure at the same time. In Zhongguancun or other demonstration zones in Beijing, a closely cooperation of universities, research institutions and enterprises are greatly encouraged. A great number of policies are made to attract, retain and motivate innovative talents. According to the figures on its official website, Zhongguancun, a national S&T innovation center, has a rather big talent pool. There are about 40 colleges and universities, more than 200 national scientific institutions, approximately 67 state-level laboratories, more than 50 national research centers and about 29 overseas student pioneer parks in the demonstration zone.

Wuhan, one of the 25 most promising cities in China, is a very important industrial base featuring high-tech manufacturing industry, automobile, biological engineering and logistic & cargo industry (as is shown in Table 1).

Table 1   Industry Development in Wuhan and Beijing

City Comparison	Industry Development
Beijing	Electronic information, bio-medicine, artificial intelligence and R&D, etc.
Wuhan	High-Tech manufacturing industry, automobile, biological engineering and logistic & cargo industry,etc.

Recent years there are several policies formulated in favor of industrial innovation, for example, policies to encourage investment in innovation, policies to encourage the establishment of national, provincial and municipal innovation platform and policies to subsidize the investment in patents. Favorable policies contribute to the formation of several industrial clusters in Wuhan, such as Optical Valley, Dongfeng Auto Town, Yangluo Development Zone and so on. There are 2827 high-tech enterprises in Wuhan in 2017 with a growth of 29.9% than in previous years. The added value of high-tech enterprises is about 267 billion yuan with a 13.3% growth. In 2017, the total number of granted patents for invention is 25528, and the total value of technical contracts is 60.32 billion yuan. Wuhan is also a city with abundant talents. There are 84 universities and collegeswith 290000 graduates in the year of 2017.

All the above figures give us a brief introduction of the current situation of industrial innovation environment in Wuhan and Beijing. It is undoubtedly that Wuhan, with various kinds of talents, is a promising city in favor of industrial innovation. The industrial innovation environment in Wuhan is positive and stimulative, but the gap between the innovation environment in Wuhan and that in Beijing is still huge. Beijing, as a scientific and cultural center, boasts more high-tech enterprises with high renown. Besides, the industrial innovation environment in Beijing embodies a close cooperation between enterprises anduniversities and colleges. For example, there are about 40 colleges and universities in Zhongguancun national demonstration zone, including some world-renowned universities such as Tsinghua University and Beijing University providing top students for the enterprises. However, the colleges and universities in Wuhan are not that relevant to the local industrial innovation. The number of graduates in Wuhan in 2017 is larger than that of Beijing, however, there are just 2827 high-tech enterprises in Wuhan which just accounts for only 10% of the total number of high-tech enterprises in Beijing (as is shown in Figure 1).
Figure 1　A Comparison between Wuhan and Beijing in the Aspects of Graduates, Universities and Colleges and High-tech Enterprises

3 Suggestions for Improving the Industrial Innovation Environment in Wuhan

3.1 To improve the policy environment for industrial innovation in Wuhan

A good and favorable policy environment can attract trans-regional investment and creative talents, which is quite decisive in regional industrial innovation. Recent years, a range of innovation policies are formulated to promote enterprises innovation, such as "Qingtong project", "Chuanggu project" and "10 policies for enterprise innovation". However, when compared with other cities, there is still a long way to go to improve the local policy environment. First, Relevant policies should be introduced to emphasize and cultivate the subject of industrial innovation, encourage the establishment of innovation platform and form strategic alliance with other research centers or universities. Second, Intellectual property protection should be strengthened and certain technical standards need to be formulated in the local policies to ensure the innovative activities are carried out in an orderly way.

3.2 To improve the industry environment for industrial innovation in Wuhan

In Wuhan,high-tech manufacturing industry, automobile, biological engineering and logistic & cargo industry are the industries with local advantages. First, in order to be more competitive in the national or world market, the range of the local industry should be widened and more potential industries could be explored. Second, the industrial structure should be optimized and the industrial planning could be reinforced. Third, more innovation platforms need to be built for those enterprises in need. Last but not least, a close cooperation and interaction between enterprises and universities should be established, which will be a win-win choice in the future.

3.3 To improve the talent environment for industrial innovation in Wuhan

Talent is a fundamental factor in industrial innovation in Wuhan. How to retain and recruit talents is and will be the top priority in innovation environment. Talent environment has been greatly improved in Wuhan recently, some policies such as "Housing voucher project for talents", "settling-down policy for university students" are formulated aiming to retain talents. However, when compared with other cities such Beijing, Shanghai or Shenzhen, the development status for talents in Wuhan is still not that desirable. In order to retain and attract trans-regional talents, Intellectual property protection should be strengthened. Furthermore, appealing offers should be provided to attract promising talents. Specific talents that are specially needed in the economic development in Wuhan should be introduced on purpose.

4 Conclusion

Innovation has become a decisive factor behind the national economic development and an effective way to promote social advancement. This paper probes into the industrial innovation environment from three different aspects, namely policy environment, industry environment and talent environment. Among the three factors discussed in the paper, talent environment is a vital factor in

industrial innovation in Wuhan and how to retain talents should be the top priority in improving innovation environment. Furthermore, favorable policy environment and the introduction of potential industries are also very practical steps to improve the industrial innovation environment in Wuhan.

Research on Financial Competitiveness of Listed Companies in the Chip Industry: Empirical Test Based on the Factor Analysis

Gao Zhenjing

School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070

(E-mail: whutgzj@163.com)

Abstract: Based on the financial data of Shanghai and Shenzhen Stock Exchanges from 2014 to 2016, this paper employed the Stata software as a statistical tool to construct the major factor that influenced the financial competitiveness of the chip industry through factor analysis, and obtained the matrix of component score coefficients, so as to measure and evaluate the financial competition for the chip industry. The study found that: profitability was the key factor; and there was still a big gap in the financial competitiveness of various companies in the industry, which was in turn weakened by the industry's performance in profitability, operating and development capacity, and the debt repayment abilities. Based on this, this paper proposed some suggestions, such as strengthening international cooperation and broadening international market as well as implementing technical innovation operating mechanism.

Key words: Chip industry; Financial competitiveness; Factor analysis; Empirical research

1 Introduction

In the 2017 report of the 19th national congress of the CPC, General Secretary Xi pointed out that "innovation is the primary driving force for development" and put forward the strategic requirement of "accelerating the construction of a strong manufacturing country and the development of advanced manufacturing".As the representative of the highest level of micro-manufacturing in the world, chip manufacturing is the core and cornerstone of the development of the information age. In recent years, with the increase in the penetration of smartphones and the promotion of the downstream application market, the demand in China's chip market has continued to be sustained, high-speed, and stable. Meanwhile, a series of supporting policies for the chip industry have been released. For example, the State Council issued the "Outline for Promoting the Development of the National IC Industry" in 2014, and implemented the program in the form of a national integrated circuit industry investment fund to provide support at the fund level (Li Fang, 2014); the Council also issued "Made in China 2025" in 2015, which mentioned that the China's chip self-sufficiency rate need reach 40% by 2020 (Meng Qingfeng, 2016), indicating the development direction of China's chip industry. At present, in face of the increasingly ferocious competitive environment at home and abroad, the chip industry needs to improve its competitiveness as the key strategic emerging industry in China. In particular, financial competitiveness is certain knowledge and innovation-centered integrated ability in favor of the exertion of corporate sustainable competitive advantages and a kind of competitive force that acts on controllable corporate financial resources after the high-efficient integration of overall business financial ability. Therefore, evaluation on the financial competitiveness of listed companies in this industry also arouses wide attention from the social public.

Currently, many scholars have carried out the research on the financial competitiveness of the chip industry. Xi Yongqin used the revised "diamond model" to explore the factors that influenced the competitiveness of integrated circuit industry based on seven dimensions (Xi Yongqin, 2015). Li Wei adopted the analytic hierarchy process to build a performance evaluation system for the chip industry on the basis of EVA (Li Wei, 2017). Based on the above, this article wielded the stata software as a statistical tool and adopted the factor analysis method to extract the main factors affecting the financial competitiveness of the listed companies in the chip industry through combining the results of the quantitative analysis, and thus to obtain a formula for evaluating the financial competitiveness of enterprises.Therefore, the objective assessment was achieved, and based on the Wilcoxon signed rank, the robustness analysis was conducted upon the empirical part of the paper. On this basis, it provides targeted recommendations for the development of China's chip industry.

2 Chip Industry Financial Competitiveness Factor Analysis

2.1 Research design

2.1.1 Research Subject and Method

This paper took 80 chip companies in the concept plates of the Shanghai and Shenzhen Stock Markets as research objects, removed missing data samples, and finally selected 60 listed companies of the chip industry as samples. Meanwhile, due to the availability of data, this paper took the period from 2014 to 2016 as the sample interval in the empirical analysis. In order to avoid data of a certain year affecting the reliability of the sample, the average of the three-year data was used as the research data. The basic principle of the factor analysis method is based on the internal correlation of research variables. The variables with high correlation are aggregated into the same type, and the correlation between different types of variables becomes low. Each type of variable actually represents a common factor.

This paper employed the stata software as a statistical tool to transform multiple financial indicators affecting the financial competitiveness of the chip industry into a few unobservable comprehensive indicators(He Xiaoqun, 2012), explore the main factors affecting the financial competitiveness of listed companies in the industry, and obtain a comprehensive score for each company so as to measure their financial capabilities.

2.1.2 Indicator selection

Corporate financial competitiveness is an integrated evaluation system. Based on relevant theories concerning corporate financial competitiveness, this paper adheres to the comprehensiveness, scientificity and equilibrium principle in indicator setting in combination with the data of listed companies in chip industry, constructs corresponding financial competitiveness evaluation indicator system from the dimension of debt paying ability, business operation ability, profitability and development ability and chooses the current ratio, quick ratio, cash ratio, total asset turnover, working capital turnover, return on assets, return on equity, operating profit ratio, ratio of profits to cost, revenue growth rate, and total asset growth rate as the variables for factor analysis. The variables are set as Table 1.

Table 1　Variable Settings

Category	Variable Name	Variable Definition
Solvency	current ratio	X1
	quick ratio	X2
	cash ratio	X3
Operating capacity	working capital turnover	X4
	total asset turnover	X5
	return on assets	X6
Operating capacity	return on equity	X7
	operating profit ratio	X8
	ratio of profits to cost	X9
Development ability	total asset growth rate	X10
	revenue growth rate	X11

2.2 Factor analysis

In order to eliminate the influence of the dimensional relationship among variables and the difference in data size and improve the comparability of the data, the original data is standardized using the stata (similarly hereinafter) and the analysis program is set, and Table 2 and Figure 1-2 are obtained in proper order.

Table 2　KMO and SMC

Variable	KMO	SMC
X1	0.6444	0.9987
X2	0.6103	0.9989
X3	0.7638	0.9768
X4	0.3534	0.1198
X5	0.4998	0.5077
X6	0.6758	0.8903
X7	0.6983	0.8600
X8	0.6680	0.8891
X9	0.6409	0.9011
X10	0.4866	0.3553
X11	0.1718	0.1064
Overall	0.6463	-

Table 2 lists the results of KMO and SMC. The KMO sampling fit measure is used to measure the correlation of the indicator, and the SMC is used to observe the linear relationship of the indicator (Zhang Hui, 2012). In this analysis, KMO=0.646>0.6 indicates that the indicators have certain correlations and are suitable for factor analysis. The SMC values of most variables are greater than 0.5, and those of the current ratio, quick ratio, cash ratio, and ratio of profits to cost are all greater than 0.9, indicating that the linear relationship between the indicators is strong and is suitable for factor analysis. The data in Table 3 shows the variance contribution rates and cumulative sums of the common factors. In general, the extraction criterion is to extract the common factor with an eigenvalue greater than 1. Stata analysis results show that the first four common factors satisfy the conditions, and their variance contribution rates are 32.21%, 27.52%, 11.73%, and 9.71% successively, and the cumulative variance contribution rate after rotation reaches 81.16%. Therefore, the first four common factors are extracted and it is representative and strongly explained.

Table 3   Total Variance Explained

Component	Eigenvalue	Difference	Proportion	Cumulative
Component 1	3.5426	0.5159	0.3221	0.3221
Component 2	3.0267	1.7369	0.2752	0.5972
Component 3	1.2898	0.2215	0.1173	0.7145
Component 4	1.0682	0.1693	0.0971	0.8116
Component 5	0.8989	0.1791	0.0817	0.8933
Component 6	0.7199	0.4171	0.0654	0.9587
Component 7	0.3028	0.2256	0.0275	0.9863
Component 8	0.0772	0.0237	0.0070	0.9933
Component 9	0.0535	0.0336	0.0049	0.9982
Component 10	0.0197	0.0191	0.0018	0.9999
Component 11	0.0006	0.0	0.0001	1.0000

As shown in Figure 1, combined with the inflection point of the curve in the gravel chart and its corresponding horizontal and vertical coordinates, it can be seen that the eigenvalues of the first four common factors are greater than 1 with steeper slope, which indicates more intuitively that it's reasonable and strongly supported to extract the first four common factors.
Figure 1   Scree Plot

Table 4 reveals the component matrix after rotation. The maximum factor variance method is used to rotate the initial factor load matrix. After the rotation, the load of the indicators on the common factor becomes larger, which can more reasonably represent the degree of influence of the indicator on the common factors and give more naming explanation to the common factor variables.

According to the rotated component matrix table, the indicators can be grouped into four main factors. The first main factor has a larger load on *X6、X7、X8、X9*, indicating that it reflects the profitability of the enterprise. Hence it is defined as the profitability factor; the second main factor has a large load on *X1、X2、X3*, showing that it reflects the solvency of the enterprise, so it is defined as the solvency factor; The third main factors has a larger load on *X4、X5*, representing that it basically reflects the operational capability of the enterprise, thus it is defined as the operational capability factor; and the fourth main factor has a relatively large load on *X10、X11*, indicating that it stands for the company's ability to develop, therefore, it is defined as the development capacity factor

Table 4   Rotated Component Matrixa

Variable	Component 1	Component 2	Component 3	Component 4
Zscore(*X1*)	-0.073	0.988	-0.046	-0.020
Zscore(*X2*)	-0.071	0.989	-0.055	-0.022
Zscore(*X3*)	-0.020	0.984	-0.108	-0.034
Zscore(*X4*)	-0.047	0.054	0.656	-0.039
Zscore(*X5*)	-0.054	-0.272	0.805	0.028
Zscore(*X6*)	0.911	-0.156	0.144	0.140
Zscore(*X7*)	0.881	-0.116	0.113	0.154
Zscore(*X8*)	0.888	-0.092	-0.219	-0.117
Zscore(*X9*)	0.851	0.222	-0.316	-0.084
Zscore(*X10*)	0.382	-0.012	0.296	0.564
Zscore(*X11*)	-0.098	-0.040	-0.164	0.874

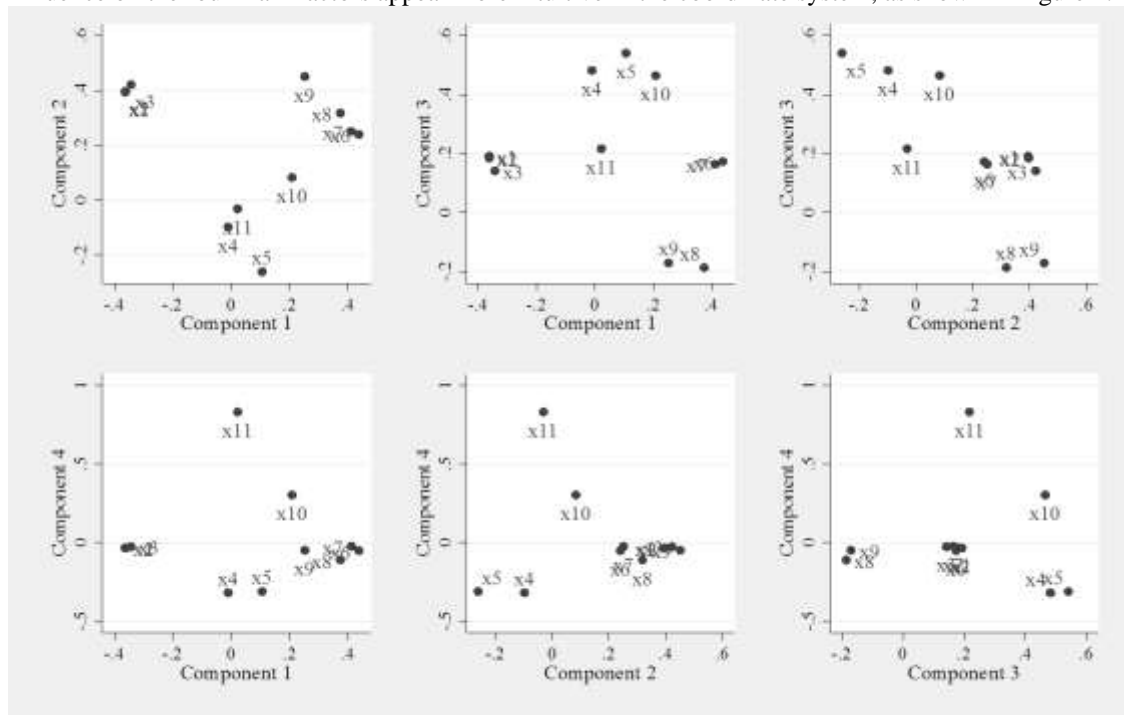
The load map can make the degree of aggregation between each variable and the degree of its influence on the four main factors appear more intuitive in the coordinate system, as shown in Figure 2.


Figure 2   Component Loadings

According to Table 5, the relevant equations can be drawn, and the scores of each factor are:
*F1 = 0.009 * X1 + 0.010 * X2 + 0.024 * X3 + 0.025 * X4 + 0.016 * X5+ 0.280 * X6 + 0.269 * X7 + 0.271 * X8 + 0.263 * X9+ 0.101 * X10 - 0.094 * X11*
*F2 = 0.333 * X1 + 0.333 * X2 + 0.326 * X3 + 0.094 * X4 + 0.001 * X5 - 0.001 * X6 + 0.008 * X7 -0.031 * X8 + 0.066 * X9+ 0.063 * X10 - 0.007 * X11*
*F3 = 0.079 * X1 + 0.072 * X2 + 0.035 * X3 + 0.513 * X4 + 0.584 * X5+ 0.133 * X6 + 0.111 * X7 -*

0.123 * X8 – 0.165 * X9+ 0.208 * X10 - 0.198 * X11
F4 = 0.023 * X1 + 0.022 * X2 + 0.011 * X3 - 0.076 * X4 - 0.037 * X5+ 0.054 * X6 + 0.072 * X7 - 0.146
* X8 - 0.097 * X9+ 0.459 * X10 + 0.797 * X1

Taking the variance contribution rate as the weight of each main factor, then the formula for calculating the composite score can be obtained as:

F = (0.3221 * F1 + 0.2752 * F2 + 0.1173 * F3 + 0.0971 * F4) / 0.8116

According to the load capacity of each main factor, the comprehensive score is:

F = 0.131 * X1 + 0.130 * X2 + 0.126 * X3 +0.107 * X4 +0.087 * X5+ 0.136 * X6 + 0.134 * X7 - 0.062
* X8 + 0.091 * X9+ 0.146 * X10 + 0.027 * X1

Table 5   Component Score Coefficient Matrix

	Component			
	1	2	3	4
Zscore(*X1*)	0.009	0.333	0.079	0.023
Zscore(*X2*)	0.010	0.333	0.072	0.022
Zscore(*X3*)	0.024	0.326	0.035	0.011
Zscore(*X4*)	0.025	0.094	0.513	-0.076
Zscore(*X5*)	0.016	0.001	0.584	-0.037
Zscore(*X6*)	0.280	-0.001	0.133	0.054
Zscore(*X7*)	0.269	0.008	0.111	0.072
Zscore(*X8*)	0.271	-0.031	-0.123	-0.146
Zscore(*X9*)	0.263	0.066	-0.165	-0.097
Zscore(*X10*)	0.101	0.063	0.208	0.459
Zscore(*X11*)	-0.094	-0.007	-0.198	0.797

Therefore, we can obtain the comprehensive evaluation scores and rankings of the listed companies in China's chip industry. The specific results are shown in Table 6:

Table 6   Score Summary both of the Top 10 and Last 10 Enterprises

Company	F1	Rank	F2	Rank	F3	Rank	F4	Rank	F	Rank
NSD	2.723	1	0.563	8	1.422	4	3.752	1	1.545	1

2.3 Result analysis
2.3.1 Overall analysis on the ranking results

As can be seen from the vertical comparison, the financial competitiveness ranking *F* has a significant correlation with the profitability factor *F1*. Except for the abnormal situations of individual companies (BJJZ、ZGGF、XSKJ), the profitability factors of the other companies are almost matching with their comprehensive ranking, which shows that the profitability is a key indicator for measuring the financial capacity of an enterprise and also is a concentrated expression of its financial competitiveness. Investors believe that listed companies with continuous profitability advantages have more investment value (Chen Lei, 2010). And enterprises should also focus on improving their profitability and guarantee the sustainable and stable development of enterprises in order to enhance their financial competitiveness.

After analyzing the scores of various factors and the overall score, there are 26 companies getting positive scores for the profitability factor *F1* and operational capability factor *F3*, accounting for 43.3% of the total sample, which indicates that in the chip industry, the volumes of companies with strong profitability and companies with weak profitability are almost the same. However, in terms of solvency factor *F4* and development capability factor *F4*, the number of companies with positive industry scores is only 12 and 19, respectively, revealing the weak overall solvency of the industry, high financial risks and weak abilities in the overall development. By descriptive statistics analysis, under the premise of the standardization of raw data, the minimum value of the operating capability factor is -2.61184 and the maximum value is 4.096681, meanwhile the solvency capability still has a minimum value of -0.97898 and a maximum value of 6.57188, which explains that there is a significant difference in the operating capacity and solvency of each company. From a comprehensive view, the performance of the chip industry in terms of profitability, operating capability, development capability, and solvency ability has been weakened successively and there is still a certain gap between the financial competitiveness of various companies.
Figure 3   Company Score Distribution Map of the 60 Samples

2.3.2 Analysis of abnormal situations in individual companies

From the score summary table, it can be clearly seen that individual companies have abnormalities between the overall financial competitiveness scores and rankings of various factors. For example, BJJZ ranks among the best in comprehensive scores, but its profitability factor*F1* ranks at the bottom. Through further comparison with the original data, this article finds that BJZZ's current ratio, quick ratio, and cash ratio indicators are as high as 55.772, 52.003, and 27.588, respectively. Meanwhile the weights of the indicators in calculating the composite score F are 0.134, 0.133, and 0.129, respectively, which are also relatively large, so that the overall ranking of the company is higher; the score of its profitability factor is low for the four indicators, including return on assets, return on net assets, operating profit ratio,

and total asset growth rate, which count a lot in calculating the score of the profitability factor *F1* and their values are 0.28%, 0.89%, -18.26%, and 1.37%, respectively, all staying at the bottom of the industry. Although there is no shortage of operating funds, the company's profitability is one of the factors directly affecting its solvency based on the sustainability of the company's development. If there is no higher profitability as a guarantee, strong solvency will not last for long, so the company should be vigilant and focus on improving its profitability.

2.4 Robustness test

In order to test the accuracy and reliability of the foregoing conclusions, the following robustness tests were conducted: as shown in Table 7, some of the indicators in the original variables were replaced, and the factor analysis was performed on the selected samples using the indicators after substitution to obtain a comprehensive ranking of the companies. The Wilcoxon signed rank test was conducted on the rankings of companies before and after the indicator replacement and the main conclusions were as follows.

Table 7   Indicator Settings

Original indicator	Robustness test indicators
Cash ratio	Assets and liabilities
working capital turnover	Account receivable turnover rate
Revenue growth rate	Net profit growth rate

Table 8   Non-parametric Test

Z	-.738b
Accuracy significance (dual-side)	0.465

According to the statistical test results shown in Table 8, the two-sided significance level is 0.465>0.05, and then it is considered that after the partial indicators are replaced, the evaluation result is not significantly different from the evaluation result under the original indicators, that is, the study is considered to be statistically robust and the empirical conclusion has strong reliability.

3 Development Suggestions in the Chip Industry

3.1 Expansion of the international market in the chip industry

The promotion of the "One Belt, One Road" policy has provided a good international environment for the development of the chip industry (Tang Yanli, 2016). China's chip industry should actively promote cooperation between companies and foreign research and development institutions, and learn the research and development experience in the high-end chip manufacturing from European and American countries. (Lin Zhangyue, 2016) At the same time, chip companies can actively expand the international market and improve the overall development capability of the industry by leveraging the downstream advantages of the industrial chain and integrating international resources.

3.2 Implementation of the technical innovation operating mechanism in the chip industry

China's high-end chip devices have limited self-sufficiency, and many high-end core technologies are still in the research and development stage (Li Lei,2008). Therefore, listed companies in the chip industry should adhere to the market-oriented concept of technological innovation, increase technological innovation and research and development investment, formulate and implement a complete, standardized, and efficient research and development management system, and always attach importance to the cultivation of technical personnel and the development of research and development teams (Bai Quanwang, 2014). Besides, they should grasp the high-end chip manufacturing process, form innovative technologies and products in the chip industry and promote the commercialization of scientific and technological achievements (Qian Chunhua, 2012), and rely on technological innovation capabilities to enhance corporate profitability and investment value so as to develop the financial competitiveness of the enterprise.

4 Conclusion

This paper selects the financial data from 2014 to 2016 of 60 companies in the chip industry in the Shanghai and Shenzhen Stock Markets as samples, and wields stata as the statistical software for factor analysis. The research shows that the four main factors affecting the financial competitiveness of the

chip industry are profitability, solvency, operational ability, and development capability, in which the profitability is a key indicator affecting the financial competitiveness of the company; the performance of the chip industry in terms of profitability, operational capacity, development capacity and solvency was weakened in proper order. From a comprehensive perspective, the support to the chip industry which is a strategic emerging industry in China, should be strengthened to promote its development. The companies with weak financial competitiveness can be active through effective mergers and acquisitions within the company, strengthening international cooperation and expanding the international market, as well as improving the technical innovation operating mechanism in order to promote the overall development of the chip industry.

Abstract: In China, local government tends to implement key R&D project to support the industrial innovation of the region, especially in the field of generic technology and high tech. This paper takes Liuzhou City as an example, conducts an efficiency evaluation based on DEA model,and analyzes the status quo and the hindering factors of Liuzhou's government-supported key R&D project via questionnaire analysis.The research shows that the most important obstacle factors of key R&D project are lack of funding, lack of policy support and unstable market environment.
Key words: Government-supported key R&D project; Technological innovation; DEA; Liuzhou city

1 Introduction

Government-supported key R&D project is a kind of government dominant program aiming at solving critical, systematic, strategic, prospective and generic technology required from the regional development (Zhao Fugang, 2009). Government-supported key R&D project focuses on great technological innovation activity with specific goal and particular target, and an important way to enhance regional comprehensive competitiveness (Li Linqiong, 2011).

There are some researches on government-supported R&D project. ĐuroKutlača described the application of a multicriteria-based evaluation and selection procedure of R&D project proposals submitted for financial support within the framework of the GIP (ĐuroKutlača, 1997).Chang P L formulated a quality management model for research institutes performing government-supported R&D projects (Chang P L, 1998).Hsu F M presented an alternative approach for assessing the relative efficiency of government-sponsored research and development projects (GSP). A three-stage approach employing data envelopment analysis to evaluate efficiency and Tobit regression to control external variables was applied to 110 projects over 9 years (Hsu F M, 2009). Euiseong Kim measured the R&D efficiency by employing data envelopment analysis (DEA) and applied Tobit regression method to find the determinant of R&D efficiency (Euiseong Kim, 2011).Ryu Y analyzed the successful factors and performance level of government-supported Creative R&D Program in Korea, a regression analysis was conducted based on the result of questionnaire (120) on researchers who participated in the program (Ryu Y, 2013).

Liuzhou is an industry city located in the west China, and is with strong advantages in the manufacturing industries such as automobile and pharmacy (Yu Huan, 2016). Recent years, Liuzhou initiated a lot of key R&D projects answering to the strategic need of the local economic development (Liu Yi, 2014). Liuzhou municipal government stick to some principles while implementing key R&D projects, which are as following: (1) combining key R&D project with huge engineering project; (2) highlighting the main body position of enterprise; (3) triggering multi-channel funding mechanisms; (4) relying on the strategic alliance. So, the government-supported key R&D project exert multiplier effect and spill-over effect in innovation driven development of Liuzhou City.

It is necessary to conduct a review about the efficiency, effectiveness and hindering factors of the implementation of Liuzhou's government-supported key R&D project in recent years.

2 The Efficiency Evaluation of Liuzhou's Government-supported Key R&D Project

We here select 13 Liuzhou's government-supported key R&D projects started in 2013,and employ DEA (Data Envelopment Analysis) to conduct evaluation of efficiency of each project. These projects covers the technological fields of pharmacy，advanced manufacturing, iron, modern agriculture, etc., which are noted as P1, P2, …, P13 respectively.

We set 3 input variables (total investment, R&D fund, patent application), and 1 output variable (profit).

Construct DEA Model as follows (ε is the non-Archimedean infinitesimal):

$$(D_{\varepsilon})\begin{cases} \min[\ \theta - \varepsilon(\hat{e}^T s^- + e^T s^+)], \\ \sum\limits_{j=1}^{n} \lambda_j x_j + s^- = \theta x_0, \\ \sum\limits_{j=1}^{n} \lambda_j y_j - s^+ = y_0, \\ \lambda_j \geq 0,\ j = 1, \cdots, n, \\ s^- \geq 0, \\ s^+ \geq 0. \end{cases}$$

The input-output data and the efficiency evaluation results are shown in Table 1.

Table 1　The Input-output Data and the Efficiency Evaluation Results

Project	efficiency	profit（10000 RMB）	total investment （10000RMB）	R&D fund （10000R MB）	patentapplicati on（item）
P1	0.199	3199.49	28629	1200	33
P2	0.047	330	11160	600	26
P3	0.714	7274	13568	1000	13
P4	1	10328	13800	1000	1
P5	1	5710	6990	800	3
P6	0.728	4778	9478	600	5
P7	0.483	844.76	3383	500	0
P8	0.196	1422	11700	600	21
P9	0.383	1247	4341	321	3
P10	0.647	2790	5289.15	600	10
P11	0.540	2845	6800	600	2
P12	1	12138	27560	600	15
P13	1	4316	8356	500	0

The evaluation results show that: (1) There are tremendous efficiency differences among projects; (2) Only 4 projects reach the efficiency frontier; (3) Many projects present very low efficiency such as P1, P2 and P8.

3 Status Quo Analysis of Liuzhou's Government-Supported Key R&D Project: A Perspective of Enterprises

Liuzhou's government-supported key R&D project is a typical triple helix process, i.e. the coordination of government, enterprise and university, in which enterprise is the main body of the implementation (Leydesdorff L, 2013). So we distributed 80 questionnaires oriented to the enterprises undertaking the Liuzhou's government-supported key R&D projects and get 48 effective respondents. We design two types of questions. The first parts are Likert scale questions, and the second parts are multiple choices questions.

As to Likert scale questions, question 1: Are you satisfied the support of the local government in the implementation of key R&D project? The response is shown in Figure 1. The figure indicates that 19% of the respondents are very satisfied with the local government support, and 48% of the respondents are fairly satisfied with the local government support.
Figure 1   Question 1 Results

Question 2: Are the key R&D projects helpful for your company's development? The response is shown in Figure 2. So we can see that the key R&D project is totally helpful for the companies.
Figure 2   Question 2 Results

Question 3: Is your company's technology sufficient for the implementation of key R&D projects? The response is shown in Figure 3. We can see that still 10% companies' technology is not sufficient.
Figure 3   Question 3 Results

Question 4: Are your company's talent personnel sufficient for the implementation of key R&D

projects? The response is shown in Figure 4. We can see that still 19% companies' talent personnel are not sufficient.
Figure 4   Question 4 Results

As for multiple choices, the typical one is: What are the main obstacles of key R%D project implementation in enterprise. The alternatives are: A-Lack of R&D personnel, B-Lack of funding, C-Communication obstacle, D-Weakness of the government policy, E-Difficulties of IP protection, F-Instability of industry environment, G-Insufficiency of coupling of technology and market, H-Weakness of marketing, I-Weakness of technology sustainability, J-Complexity of project coordination, K-the others. The results are shown in figure 5. The figure indicates that B, C, D and F and the most important obstacles to the implementation of Liuzhou's government-supported key R&D project in the perspective of enterprises.
Figure 5   The Obstacles of Liuzhou's Key R&D Project Implementation

4 Conclusion

The study shows that the Liuzhou's key R&D projects have a relatively satisfied efficiency with the huge differences among various projects, and they are helpful for the local enterprise's technological innovation and business development. The research also indicates that the most important obstacle factors of key R&D project are lack of funding, lack of policy support and unstable market environment.

The countermeasures to raise the efficiency include: (1) Enforce the cooperation among enterprise, university and government; (2) Recruit more talent personnel to enterprise; (3) Improve the industrial innovation environment.

Political Gene, R&D Investment and Corporate Innovation Performance: An Empirical Study

Chen Xuan

School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070

(E-mail: chenxuan1403@yeah.net)

Abstract: Under the new normal economic background, innovation is an important strategy for the transformation and upgrading of Chinese metal products industry. This paper takes the listed companies of Metal Products Industry from 2014 to 2016 in Shenzhen and Shanghai Stock Exchange as the research object. This article constructs multiple linear regression models to empirically testing the impact of corporate political gene on innovation performance and examining the intermediate effects of R&D investment of the two. The study finds out that the two dimensions of corporate political gene, namely the ownership structure of enterprises and the political connections of senior executives, have a positive effect on corporate innovation performance. R&D investment has incompletely intermediate effects in the above process.

Key words: Political gene; Innovation performance; R&D investment; Metal products industry

1 Introduction

1.1 Research background

It is widely acknowledged that technological change and innovation are major drivers of economic growth and lie at the very heart of the competitive process. Under the background of the long-term implementation of the planned economic system in China, the relationship between the enterprise and the government is close. The bond between the two is usually linked through the company's political gene which can be explained as the ownership structure of the company and the political connections of senior management. The political gene of an enterprise determines the acquisition of political resources which are related to the enterprise's innovation decisions and ultimately affect the innovation performance of the enterprise (Wang Yanyu, 2014).

1.2 Literature review

Scholars at home and abroad have been studying the influence of political association and corporate performance for a long time, but the results have been mixed for positive and negative effects. Some scholars think that social capital obtained through political connections will have a positive effect on corporate performance (Li, 2008).The private enterprise datashows the political association of senior executives has positive influence on enterprise performance (Tang Linxia, 2015). Some scholars use real estate companies as a sample to conclude that political connections will weaken the performance level of enterprises (Yang Dongjin, 2013). Some studies have pointed out that there are risks in the social capital that enterprises have. The rent-seeking costs that companies need to pay for acquiring political resources may squeeze the company's R&D resources and have a curse effect on corporate performance (Yuan Jianguo, 2015).The existing literature is mostly limited to the relationship between the political association of senior executives and corporate performance. There is less discussion on the ownership structure of the enterprise whichisthe other dimension of the political gene. The focus of the research is mainly on the financial performance of the enterprise. The attention to the innovation performance of an industry is still insufficient, which is obviously not consistent with the national conditions of China's vigorous implementation of the innovative development strategy.In this context, it is necessary to explore the relationship between political gene and innovation performance.

1.3 Research strategy

The article is organized as follows. The next section contains the theoretical deduction and hypothesis. This section introduces the theory underlying the article and proposes hypotheses. The third section contains a description of the data source and the variables used in the empirical analysis. Besides, the model used in the article is also introduced. The fourth section empirically explores the role played by political gene in explaining the innovation performances of mental products firms in a regression framework. The concluding section summarizes the main empirical findings and proposes relevant suggestions.

2 Theoretical Deduction and Hypothesis

2.1Political Gene and Corporate Innovation Performance

Enterprise innovation activity is a long-term sustainable process that requires enterprises to obtain resources from both internal and external sources. Relying on China's special capital market situation, political gene can be objectively measured from the two dimensions of ownership structure and executive politics.Because of the long-term planned economic system in Chinese history, the controlling shareholders of many listed companies are state-owned.Since political gene is the link between corporate governments and an important way for companies to obtain social capital, companies with political gene can acquire more political resources to some extent.In addition to government resources, state-owned holding companies can also get more support in financing (TseJiazhi, 2014). Corporate executives have a major impact on strategic choices, especially resource allocation decisions, and the impact on corporate R&D investment is particularly significant. In state-owned enterprises, corporate executives tend to be more innovative in seeking innovative opportunities, increasing innovation and improving performance.Based on the above analysis, this paper considers that enterprises with political gene is beneficial to enterprises to improve their innovation performance. Therefore, the first hypothesis is following proposed:

H1a: There is a significant positive correlation between corporate ownership structure and innovation performance

H1b: There is a significant positive correlation between executive political correlation and innovation performance

2.2 Corporate R&D investment and corporate political gene

Based on the above-mentioned literature, we can discover the path of the political gene's impact on the company's innovation performance is indirectly achieved through R&D investment. R&D investment represents the company's strategic commitment to innovation and the degree of emphasis.At present, most empirical studies have shown that companies with political gene is more likely to obtain loans. The loans can be invested to the introduction of personnel and the purchase of equipment to improve the innovative level. Besides,enterprises with political gene is more likely to receive government subsidies and policy support. The increase in government investment can significantly promote innovation activities in high-tech industries (Wang Yuanhe, 2015). In addition to financial factors, the senior executive of the company attaches importance to the introduction of talents.Attracting more innovative talents for enterprises and increase the investment of R&D personnel.Since ownership structure and executive political connections bring more social capital to enterprises, enterprises have the ability to meet the salary requirements of high-tech technical talents, attract more innovative talents for enterprises, and increase investment in R&D personnel.Therefore, the second hypothesis is following proposed.

H2: There is a significant positive correlation between R&D investment and corporate political gene.

2.3 The mediating effect of corporate R&D investment

R&D investment is the distribution of resources for innovation and determines the success or failure of innovation activities. The reasons for the influence of political genes on innovation performance can be explained by both the ownership structure and the political connections of executives. The amount of innovative resource allocations ultimately leads to differences in innovation performance.Resource allocation is a necessary link for corporate executives to identify external political network resources and act on innovation outcomes. R&D investment is the resource allocation of enterprises for innovation and plays an important role in innovation performance. In the decision-making process of resource allocation, the ownership structure has important influence on various decision-making activities. State-owned holding companies have advantages in accessing social resources, so they have more funds to invest in R&D. On the other hand, the government has control and often considers the social environment or policies in decision-making, which may affect the allocation of corporate resources.Because of the discretion of business executives, their behavioral and psychological characteristics can affect the resource allocation decisions of the company (Chen Jiawen, 2016). Exploring the influence of corporate political relations on the process of enterprise innovation is conducive to understanding the mechanism of political genes affecting the innovation performance of enterprises. Therefore, the third hypothesis is following proposed.

H3：R&D investment has intermediate effects between political gene and corporate innovation performance.

3 Data and Methodology

3.1 Sample selection and data sources

This paper selects listed companies in the metal products industry in Shenzhen and Shanghai Stock Exchange from 2014 to 2016 as the research object, and the data mainly comes from the CSMAR database, the WIND database, the company's annual report and the patent search website of the State Intellectual Property Office. Excluding companies with incomplete information disclosure and ST processing, we obtained a total of 36 listed companies' data from 2014 to 2016. All data processing in this paper was completed with Stata 14.0.

3.2 Method

This paper mainly includes the regression of political genetic variables on innovation performance, which includes the mediating effects of R&D investment on political gene and innovation performance.We draw lessons from the former researches and designed the following models:

$$Patent_{it} = \beta_0 + \beta_1 State_{it} + \sum_{k=1}^{n} \lambda_i \times Control_{it} + \varepsilon_{it} \tag{1}$$

$$Patent_{it} = \beta_0 + \beta_1 PC_{it} + \sum_{k=1}^{n} \lambda_i \times Control_{it} + \varepsilon_{it} \tag{2}$$

$$INRD_{it} = \beta_0 + \beta_1 State_{it} + \beta_2 PC_{it} + \sum_{k=1}^{n} \lambda_i \times Control_{it} + \varepsilon_{it} \tag{3}$$

$$Patent_{it} = \beta_0 + \beta_1 State_{it} + \beta_2 PC_{it} + \beta_3 INRD_{it} + \sum_{k=1}^{n} \lambda_i \times Control_{it} + \varepsilon_{it} \tag{4}$$

Where:

$Patent_{it}$ is the technical innovation performance of firm i at time t;

$State_{it}$, PC_{it} are dummy variables represent corporate ownership structure and executive political association of firm i at time t;

$INRD_{it}$ is a mediator that represents R&D input intensity of firm i at time t;

$Control_{it}$ are the controlled variables, which is the scale of the company(Size), return on net assets(ROE), asset-liability ratio(LEV), shareholding concentration(LS), managerial ownership ratio, (Manager) year of company establishment(Age) and regional marketization index(Region).

ε_{it} are random error terms with the usual assumptions.

4 Results

4.1 Descriptive statistical analysis

From the descriptive statistics are shown in Table 1, the average value of the innovation performance of the explained variable is 0.01. The result shows that the average number of patent applications per million yuan of assets in the current year is 0.01, and the minimum value exists as 0. We can find out that the innovation performance of metal products industry is relatively low and there is a big gap between different companies.The average R&D investment intensity is 3%, which reflects the strong innovation input characteristics and there is a large gap between the R&D input intensity of enterprises.The average shareholding ratio of the largest shareholder is 35%, which indicates that the sample company's major shareholder has a relatively small shareholding, and the shareholding ratio is between 9% and 81%. The span is large, but the shareholding is generally relatively dispersed. The average degree of marketization of enterprises is 83%, indicating that 83% of enterprises are in a market-oriented region.

Table 1　Variable Descriptive Statistics

Variables	Mean	Std. Dev.	Min	Max
Patent	0.01	0.02	0.00	0.09
State	0.14	0.35	0.00	1.00
PC	0.21	0.41	0.00	1.00
INRD	0.03	0.02	0.00	0.11
Size	22.01	1.04	20.26	25.55
ROE	0.05	0.08	-0.33	0.28
LEV	0.41	0.18	0.15	0.90
LS	0.35	0.13	0.09	0.81
Manager	0.07	0.12	0.00	0.44
Age	17.36	5.00	7.00	36.00
Region	0.83	0.37	0.00	1.00

4.2 Regression analysis

Table 2 shows the regression analysis results. It indicates the hypotheses proposed in this paper have all been verified. It can be seen that there is a significant positive correlation between innovation performance and political gene. After joining the R&D investment intensity, there is no significant correlation between executive political relations and innovation performance. Although the ownership structure and innovation performance of enterprises are still significantly correlated, the level of correlation is significantly reduced. R&D investment intensity is still significantly related to innovation performance at 10%. It means R&D investment has incomplete intermediation between the two.

Table 2   Regression Analysis Statistics

5 Conclusion

5.1 Research conclusion

This paper relies on corporate gene theory as a framework to explore the relationship between corporate political gene and innovation performance, and to examine the intermediary role of R&D investment in it. We regress the panel data of 36 listed companies in Chinese metal products industry from 2014 to 2016. The research results of this paper manifests political gene in a significant positive impact on the innovation performance from the ownership structure of companies and the political connections of senior executives.R&D investment has an incomplete mediating effect on political gene and innovation performance. The link of "political gene—investment in R&D—innovation performance" reflects the potential path of corporate innovation and shows that R&D investment plays a key role in it. The indirect link of "political gene-innovation performance" illustrates the state-owned holding property of enterprises and the social network income of senior executives need internal transformation to function on the innovation results (Shu, 2012).

5.2 Suggestion

In order to further improve the level of enterprise innovation and enhance the ability of independent innovation, the following suggestions are proposed:

(1) Establish good and healthy relations between the government and enterprises.

(2) Enterprises should rationally allocate resources in accordance with their actual conditions.

(3) While implementing the political strategy, attention should be paid to the integration with the market strategy.

5.3 Research prospects

We shall increase the number of samples, extend the research to the whole industry and subdivide political genetic variables in further research.

Abstract: Traditional Chinese architecture is highly favored by construction enthusiasts, artists, Chinese culture enthusiasts, and some scholars around the world. It is very urgent to cultivate translators with qualified competence in translating traditional Chinese architecture texts. The Aesthetic Approach has been adopted as the research method of this study. Based on the theory of Translation Aesthetics, this paper analyzes the aesthetic aspects of the traditional Chinese architecture texts from the aspects of beauty of fuzziness, beauty of logicality, and beauty of image, as well as the strategies that should be taken concerning the innovative cultivation of the translators. This paper holds that in addition to the necessary bilingual competence, professional competence and aesthetic capability are all indispensable to a qualified translator. Both of these abilities are indispensable in all aspects of translation aesthetic practice.
Key words: Innovative cultivation; Translators; Traditional chinese architecture; Translation aesthetics

1 Introduction

Traditional Chinese architecture text refers to the text that introduces, disseminates, records and preserves contents concerning the traditional Chinese architectures. Although traditional Chinese architecture is highly favored and concerned by construction enthusiasts, artists, Chinese culture enthusiasts, and some scholars, books and literatures on traditional Chinese architecture written in foreign languages are rarely found to be published, so does its translation studies. In China, there is almost no uniform standard or norm for the translation of traditional Chinese architecture, and no relevant professional bilingual dictionary on traditional Chinese architecture terms has been published until now. One of the major reasons for this gap is that the number of translators being qualified in translating traditional Chinese architecture texts is quite few. It is very urgent to cultivate translators with qualified competence in translating traditional Chinese architecture texts.

Translation Aesthetics theory emphasizes both the scientific and artistic aspects of translation and can be applied to different kinds of texts, while various text types may require different kinds of aesthetical standards. It aims to represent the aesthetical aspects of the original texts in the target language, and it emphasizes bilingual transformation which makes the comparative analysis method as the major approach in Translation Aesthetics. (Fu Zhongxuan,1993) Under the perspective of Translation Aesthetics, translation process is an aesthetic activity in which "aesthetic subject (the translator) converts one kind of aesthetic object (the source text) into another kind of aesthetic object (the target text) through aesthetic medium (translator's aesthetic consciousness)" (Fu Zhongxuan, 1993) According to the definition, all the aesthetical aspects are based on the source texts. The translators read the source texts and their aesthetic consciousness will be aroused based on the aesthetic object they are reading, and a target text will be produced by translators through representation of the aesthetic aspects of the source texts.

Translation studies and Architecture studies have been said to have the same Aesthetic origin, both of them are providing aesthetic products to readers and appreciators. The difference is that translation products are collection of words while architectures are piles of building materials. Nevertheless, attaching the aesthetic attribute to their productions that can be perceived by the readers is their common aim. (Zhang Lingqian, 2013) Thus this paper will study on the cultivation of translators for traditional Chinese architecture texts by adopting the method of Aesthetic Approach.Following this trend, the traditional way of cultivating translators has been unable to meet the new requirements of translators: representation of the beauty of the source text. Under the guidance of Translation Aesthetics, analysis on the aesthetic features of the traditional Chinese architectural texts is the ability translators should have, and it is also of great significance for guiding the cultivation of the translators on these types of texts. The theory of Translation Aesthetics has raised new and higher requirement for the cultivation of traditional Chinese architecture texts translators. Based on Translation Aesthetics, this paper explores

the aesthetic characteristics of traditional Chinese architectural texts, and proposes some tips on the innovative cultivation of translators' capabilities.

2 The Aesthetic Aspects of Traditional Chinese Architecture Texts
2.1 Beauty of fuzziness
　　Fuzziness is said to be as an "objective attribute" of human language. (Mao Ronggui, 2005) As for Translation Aesthetics, fuzziness or artistic fuzzy languages refer to the language with vague and broad semantic denotation, which is regarded as precision in a higher level since they leave space for readers to think of and digest with their own imagination. The beauty of fuzziness has been regarded as "sense of mystery" by western artists. (Liu Miqing, 2016) When first reading such texts, readers will be difficult to understand them for a while; however there exists a force to attract them to continue reading, until suddenly be enlightened. At this point, fuzziness can be seen as an artistic means and artistic state, such as polysemy, ambiguity, and pun, which could produce an unexpected artistic effect. (Mao Ronggui, 2005) Uncertainty and fuzziness are said to be the main beauty of Chinese grammar system. Subject is often omitted in Chinese sentences; such structure has been called as a beauty of Chinese. Having no subject in the sentence is not only making the sentence to be concise, but also producing an enticing uncertainty, since they bring readers closer, giving the reader a sense of intimacy. (Liu Miqing, 2011)
　　In Chinese traditional architectural texts, the appearance of fuzziness phenomenon not only reflects the hazy beauty of Chinese architectural culture, but also stimulates readers' imagination. For example, some of the architectural terms tend to be fuzzy: "Xieshan", "Xuanshan", "Yingshan", "Niutui". (Lou Qingxi, 2008); any readers without any knowledge of traditional Chinese architectures will be confused by those terms if they never resort to the dictionary. Taking the term "Tiao" as an example; literally, it means "jump". The doubt on how the "jump" has been used in denoting the traditional Chinese architectures arouse the readers' interests to know more about it. Actually, "Tiao" is "an upward projection or tier of a bracket set outward or inward". (Liang Sicheng, 2001) And after a better understanding on it, the readers will be amazes by the wisdom of Chinese people.

2.2 Beauty of logicality
　　There are large varieties of traditional Chinese architectures in different shapes, showing different characteristics according to different functions and different levels of occupants. When introducing the traditional Chinese architectures, how to classify them in an orderly manner by using clear and logical language in the texts has become a major difficulty for relevant scholars. However, traditional Chinese architecture texts have always tried to keep the languages to be logical and organized, so that the well-arranged and rigorous wording provide readers with a clear logicality and rational thinking, reflecting the logicality beauty of traditional Chinese architectures.In addition to the logical relationship between texts and paragraphs, Chinese architectural texts are also logically arranged at the sentence level and have a stronger sense of reasoning to make readers feel the logical beauty of traditional Chinese architectures. For instances:
　　Curved roof and curved eave lines with four raised roof corner, the house is like a bird, flying toward the clouds with head raised high. And the big house roof would seem light in weight and graceful, instead of being clumsy. (Lou Qingxi, 2008)
　　In this case, the causal relationship is clearly presented to readers. Expressing the beautiful lines and shapes of the roof, the conditional sentence has expressed the reason why the big roof is light and practical. The characteristic that the curve of the roof is upturned is not only of aesthetical significance, but also has the practical significance of reducing the load has been presented clearly and logically.

2.3 Beauty of image
　　In translation aesthetics, image is considered as the combination of the subjective sentiment of the author and the external object or the incarnation of the text. (Liu Miqing, 2005) That is to say, the author expresses the subjective wishes by means of objective things, and combines emotion with scenery. In traditional Chinese architectural culture, there are also some traditional images that are proud by Chinese people, which are also reflected in the architectural texts. For instance, the Chinese dragon represents the emperor and the holy, the phoenix symbolizes riches and honor, while the tiger symbolizes the invincible might and power.
　　Almost all parts of the buildings within the Forbidden City described in the texts are decorated with Chinese dragon, and various forms of dragon are presented, like "sitting dragon", "creeping dragon", "two dragons playing with a pearl", and "coiled dragon". Different dragons are in different postures

with various type of beauty, some are static while some are dynamic. However, all these dragons have expressed the dignity and rights of the owner of the house.

3 An Innovative Cultivation of Translators

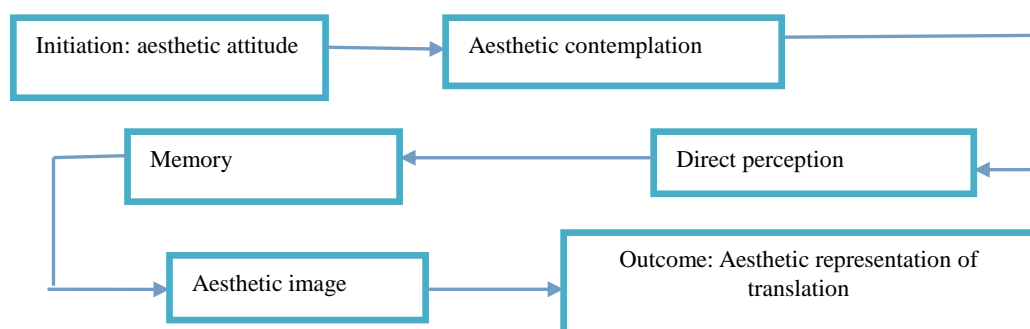
Translating Aesthetic Subject means the people involved in the process of translating aesthetic practice, that is, translators. (Liu Miqing, 2016) Under the guidance of aesthetic experience and aesthetic theory, the aesthetic subject conducts a series of aesthetic activities, taking source text, one of the translation aesthetic objects, as the center, to complete the translation activities. In which aesthetic subjects will experience a series of translation aesthetic psychological process, as shown below:


Figure 1   The Diagram Form of Aesthetic Psychological Process of the Aesthetic Subject (Liu Miqing, 2016)

It can be seen from the form above that the translating subject needs to master certain kind of ability to participate in the above conscious and unconscious mental activities necessary for translation. As in the process of English translation of traditional Chinese architecture texts, the translator needs to have certain capabilities, like solid bilingual competence and professional knowledge of traditional Chinese architecture. And the final aesthetic representation requires the translator to have sufficient English skills and aesthetic capability to adjust the target text until a perfect version comes. Therefore, if the translator wants to be able to perfectly represent the beauty of the source text in the translation, he must first have the following abilities:

3.1 Bilingual competence

A qualified translator must have qualified bilingual competence. The language competence mentioned here not only refers to the phonetic structure, lexical, grammar, sentence structure, and textual meanings of a language, but also includes appropriate use of the language in specific contexts. As Liu Miqing has indicated in his book *On Translation Aesthetics*, language competence plays a paramount role in translation.(Liu Miqing, 2011) Such competence include: (1) accurately grasp of the meaning of the source text, including the decoding of semantic information and aesthetic information; (2) the mastery of the optimal representation of source text in the target language in pragmatics; (3) language competence is the initiator of the translation aesthetic activity, as well as the prerequisite for the entire psychological activity of the translation subject. What's more important here is that bilingual competence refers to the language competence concerning both the source language and the target language. In the process of English translation of traditional Chinese architectural texts, both English and Chinese are bound to be involved in.

When translating traditional Chinese architecture texts, the translator should first have a higher level of Chinese, be able to read and appreciate Chinese traditional architectural texts, understand the connotations and denotations of the texts, and sense the aesthetic information contained in the texts. Also, the translator shall be proficient in English as well and shall be able to represent all the meaning and aesthetic information contained in the source text. A translator unqualified in Chinese is difficult to find the aesthetic information and pragmatic meaning implied in the source texts. And if his English is not proficient enough, it is difficult or even impossible for the translator to represent the aesthetic information of the source texts to let the target readers have the same feeling on the beauty of Chinese architecture and Chinese philosophy contained in the traditional Chinese architectural texts with that of the original readers. Therefore, a higher bilingual competence is a prerequisite for translators on translating traditional Chinese architecture texts.

3.2 Professional competence

The main purpose of traditional Chinese architectural texts is to introduce and inherit the traditional

Chinese architectural techniques, architectural skills, and decorative means and so on. As for the description of the complicated Chinese traditional architecture technique, it is inevitable to use some professional terminology. Qualified bilingual competence shall never be the last competence needed for a translator. Professional competence is also another important ability that must be mastered by the translators, since traditional Chinese architectural texts usually concern technical information and special terms. For some translators who might not be able to understand any specialized architectural terms, it is even more difficult for them to reasonably represent the meaning or the aesthetic value of the source text in the target text. Besides, with the development of the modern construction industry, the development and promotion of traditional Chinese architecture has been impacted, making the number of masters being proficient in ancient Chinese architectural terms be on the decrease, let alone experts with both proficiency foreign language and knowledge on ancient architectural terms, which results in the former stated dilemma faced by the English translation of traditional Chinese architectural terms.

Translation of the terms is the prerequisite and foundation for translating the Chinese traditional architecture. The premise of translating a term is that the translator shall have a fully understanding on the denotations and connotations of the terms, which objectively requires the translator to have certain professional knowledge so as to accurately understand and translate the most critical and core technology terminology of traditional Chinese architectures.

Therefore, as a qualified translator, it is important to know the corresponding professional knowledge when carrying on the traditional Chinese architectural texts translation. The translator shall not only be responsible for himself as a translator but also for hundreds of millions of readers, be responsible for the traditional Chinese architecture. If the professional knowledge of a translator is lacking, it is bound to produce the low-level mistakes in the translation, resulting in mistranslation, which cannot faithfully convey the true meaning of the source text, let alone elegantly represent the aesthetic aspects of the source text.

3.3 Aesthetic capability

Aesthetic capability is the ability of people to accept, transmit, store, process, transform and regenerate aesthetic information, forming from life practice, aesthetic practice, learning and training, and it is human specific. (Liu Miqing, 2016) As far as the translators are concerned, they need to be able to identify and understand the aesthetic information of the source text, and then through a series of processing and transformation, the aesthetic information of the original language shall be represented in the target language. Aesthetic capability is embodied in aesthetic comprehension, aesthetic imagination, and aesthetic creativity. After the translator has grasped the overall information of the aesthetic information of the source text, he depicts the scenes, images and impressions of the written words in his mind and creatively reproduces the artistic value of the source texts through the imagination of the aesthetic subject. A translator with high aesthetic capability can quickly, completely and profoundly grasp the aesthetic qualities of the aesthetic object and can accurately describe and interpret the aesthetic object. (Liu Miqing, 2016) For translators lacking in aesthetic capability, they may not be able to accurately detect and analyze the aesthetic information of the source text, let alone representing them in the translation. It is evidently that aesthetic capability is of great importance to the translator.

Instead of the function of introducing the traditional Chinese architectural technology, traditional Chinese architecture text also contains its profound aesthetic values. Its aesthetic characteristics are represented in the language structure, word meaning, textual connotations of the source language, as well as hyper texts (meanings beyond texts). Under the premise of aesthetic comprehension, the translator must grasp the overall aesthetic structure of the source text from the part to the whole. After grasping the aesthetic information of the source text, the translator is required to process and transform the aesthetic information in the brain. During this period, the translator's aesthetic imagination is involved in. After reading the original text, the translator's mind will portray all the elements including the scene, the picture, the plot, the process, the events, and the characters involved; then the translator needs to comprehend the meaning and implied meaning therein, as well as the cultural features. After the overall idea of the source text has been shown in his brain as a whole, the translator needs to exert his most important capability, the aesthetic creativity, to creatively represent the "aesthetic images" formed through imagination in his mind in the translation. Through personal experience and aesthetic contemplation, the translation will be modified until an optimized translation is achieved. Therefore, in the practice of translation, Aesthetic comprehension, Aesthetic imagination, and aesthetic creativity are all inevitable capabilities required for the translator; they role together, supplement each other, and penetrate the whole aesthetic translation practice from beginning to the end. The translator should fully develop these three kinds of capabilities, give full play to them in the practice of translation, and never

stop on the path of seeking better translations.

4 Conclusion

Traditional Chinese architecture is the crystallization of Chinese national wisdom for thousands of years. It is the embodiment of ancient Chinese science and technology progress in the construction industry. Understanding and promoting traditional Chinese architecture is an inevitable choice for understanding and carrying forward the traditional Chinese architectural culture and exploring the essence of traditional Chinese architectural techniques. Architecture is a material carrier of a nation's culture, and embodies the philosophical spirit and ethical ideas of the nation. To interpret them correctly and completely is of vital importance to carry forward China's ancient culture and spirit and enhance our international influence and competitiveness.

According to the empirical study on the Chinese traditional architecture texts, the book*Traditional Architectural Culture of China* (Lou Qingxi, 2008), some of the major beauty qualities of traditional Chinese architecture texts have been found, such as beauty of fuzziness, beauty of logicality, and beauty of image.The translation aesthetic subject is the main bearer of the translation task, and plays a subjective role in the completion of translation aesthetic practice. In addition to the necessary bilingual competence, professional competence and aesthetic capability are all indispensable to a qualified translator. Both of these abilities are indispensable in all aspects of translation aesthetic practice. For those translators engaged in the translation of traditional Chinese architecture texts, they can look up from these three perspectives, find out their deficiencies and improve their comprehensive quality and capability as a qualified translator.

Reform of Rural Land Property Rights System, Integrated Urban-rural Development and Rural Vitalization in China

Chen Yuhua

School of Foreign Languages, Wuhan University of Technology, Wuhan, P.R. China, 430070

(E-mail: 1084388123@qq.com)

Abstract: Reform of rural land property rights system is to promote the free flow of rural land resources, connect and aggregate urban capital, talent, technology and other factors so as to achieve rural vitalization under integrated urban-rural development. This paper analyzes the problems existing in the reform of rural land property rights system in China, such as the inadequate implementation of the mortgage function of land management rights, the difficulty of issuing certificates for housing estates (farm houses), and the small scope of rural collective construction land equivalent to the implementation of the marketetc. The direction of the next step of reform is to fully implement the separation of the "three rights" of rural land. For the housing land and collective construction land, we must break through institutional barriers, accelerate the empowerment and establish a reasonable interest distribution mechanism.

Keywords: Rural vitalization; Separation of three rights; Collectively owned construction land; Compensated pull-out

1 Introduction

The Chinese government has proposed to implement a rural revitalization strategy with a view to realizing industrial prosperity, ecological livability, rural civilization, effective governance, and affluent life in rural areas. This round of rural vitalization takes a radical path which aims to build a community of urban and rural development. The key to the success of this path lies in the achievement of the free flow of urban and rural resources.Land is not only the most fundamental and important resource element in rural areas but also the link of gathering people, wealth and other resources (Musole Maliti,2009). At present, the biggest obstacle to the free flow of land resources is problems regarding property rights. The unclear rural land property rights along with the incomplete empowerment and the immature market restrict the free flow of land resources.

There are three main types of land resources in rural areas: contracted land, homestead and collectively owned construction land. Overall, the reform of the rural land property rights system based on "three types of land"is progressing steadily, and the mobility of land resources has increased, but there is still a certain distance from realizing the free flow of rural land resources between urban and rural areas. To fully realize the free flow of land resources in rural areas and optimize the distribution, it is necessary to make breakthroughs in the legal level, reforms and innovations in the system as well as exploration and practice in ways to attain goals on the basis of collective ownership of land. Based on the reform practice in Wuhan and other regions, this paper focuses on the problems and causes of the reform of rural land property rights system in China, and proposes the reform direction and path of the three types of land in the future.

2 The Importance of Reform of Rural Land Property Rights System

2.1 The reform of rural land property rights system is the precondition of invigorating the rural idle land resources

With the increasing industrialization and urbanization in China, a large number of rural residents leave the countryside to work in the city. The number of migrant workers entering the cities in China reached 286.52 million in 2017, which corresponds to a sharp reduction in the population of rural residents from 745.44 million in 2005 to 576.61 million in 2017. Meanwhile, great changes have taken place in the rural population structure of China. The decrease in the rural population and the aging of population have caused severe problems: the land was uncultivated due to lack of people or ability, and the house was unoccupied or had a low utilization rate, leaving valuable land resources idle.   The rural land resources market is immature and land resources mobility is not high, some land resources have been idle for a long time, forming an unreasonable pattern of resources distribution features "available land not being used and failure to get land". This has caused a waste of land resources and is also detrimental to the increase in farmers' income, agricultural modernization, and rural vitalization.

2.2 The reform of rural land system is the breakthrough to realize the two-way flow of urban and rural resources

The urban and rural areas are divided into two separate marketsin the era of planned economy, causing the stagnation of important market factors such as the urban and rural labor force and land as well as the inefficient distribution of resources. It is also an important reason for the long-term poverty and backwardness of rural areas in the era of planned economy(He Xuefeng, 2010). After the reform and opening up, with the gradual establishment of a socialist market economy, a unified national product market has been built. The reform of the rural property rights system with land as the core is in its infancy, resulting in obstacles to the transfer of urban capital, talent, technology and other factors to rural areas and poor motivation. Land is the core resource. Only through the reform of the rural land system and the realization of the free flow of rural land can we open the channels for the flow of urban and rural resources and promote the integrated urban-rural development(Ma Chichun, 2018).

2.3 The reform of rural land property right system is an important prerequisite to realizing industry prosperity

In the early period of reform and opening, the reform of household contract responsibility system with "separation" as the main part overcame the disadvantages of excessively centralized management, single management mode and "eating from the same big pot" in the period of People's Commune, allowing hundreds of millions of farmers to gain full right of autonomous management and greatly mobilizing the enthusiasm for production(Cheng Yu, Chen Chunliang, 2017). By the middle of the 1980's, people in rural areas could have adequate food and clothing and they lived a fairly comfortable life by the end of 1990. With the increasing demand for green and safe agricultural products, small-scale peasant economy hinders agriculture from being large-scale, mechanized, brand-development focused and eco-friendly, requiring the land to be "unified"(Guo Zhong-xing, Luo Zhi-wen, 2012). "The separation of three rights" of land realizes the free transfer of the land management right, allowing land to be specialized gradually as the family farm, the specialized farmers' cooperatives and agricultural business, and the agriculture to be moderately large-scale farming. According to the implementation of the separation of three rights in Wuhan, the proportion of land flowing over 200 mu is more than 40%. Next, in order to realize the industrial vitalization, the integration of the primary, secondary and tertiary industries must be achieved and obstacles to the land development must be eradicated.

Table 1   The Relationship of "The Separation of Three Rights"

Three Rights	Attribution	Right
Land property	Belonging to the collective	Rights including reissue, supervise land use, income rights, etc.
Land contracting rights	Belonging to farmers	Rights including use, transfer, mortgage, income rights, etc.
Land management rights	Belonging to the farmer or lessee	Rights including use, mortgage, income rights, etc.

2.4 Reform of rural land system is an important way to increase farmers' property income

The income structure of rural residents has also changed dramatically in 2017, and property income accounts for only 2.2%, which is 7.53% lower than that of urban residents. According to the implementation of "the separation of three rights" of contracted land, farmers can transfer the land management right and thus gain profit by leasing or becoming shareholders. Or they can also voluntarily pull out of the contracted land and obtain corresponding compensation. For example, farmers participating in the transfer of land rights transactions in the Wuhan municipality can obtain 2625 yuan rent income annually; in Yunfeng Town, Cangxi County, the average household income from the transfer of land increases by more than 1700 yuan. Homestead and agricultural housing are also important channels to increase farmers' property income. According to the implementation of the "Three Township Project" in Wuhan, in 2017, a total number of 10078 rental agreements regarding idle rural housing was signed, and the annual rent reached 149 million yuan; the increase in total property income, salary income, and operational income of farmers reached 22.12 billion yuan, contributing 56.42% to the annual expected growth of farmers' income (Wuhan Countryside Comprehensive Property Exchange, 2017).
Figure 1 Rural Residents' Income Structure in China

3 The Status Quo and Deficiencies of the Reform of Farmland Property Right System

3.1 Although the "separation of three rights" of contracted land has been fully carried out, the functions of mortgage and guarantee have not been comprehensively implemented

At present, the separation of three rights of rural land has made significant progress in terms of the certification and registration of land rights, construction of trading market of property rights, and transactions of land transfer. According to the statistics of the Ministry of Agriculture, by the end of November 2017, the total confirmed area of rural contracted land reached 1.11 billion mu, accounting for 82% of the contracted land of the second batch of householdsin China. By 2018, China will complete the registration of rights(Shao Haipeng, 2017). In terms of the transfer of land, 35% ofland has been transferred in China. The rate of land transfer in the eastern region is higher than that in the central and western regions and it has reached more than 50%.

There are also some problems in the process of implementing "the separation of three rights" of contracted land. First, the mortgage and guarantee of the land management rights is not in place. Most areas apart from Wuhan and other few areas in China have not yet realized the mortgage and guarantee of the land management rights and lessees still fail to finance by mortgaging their land management rights in financial institutions. Second, the second-hand transfer of land management rights is not smooth. When the lessee has difficulty in operating or face bankruptcy, the second-hand transfer of land management rights is inevitable. However, the process of a second transfer is hard due to tedious procedures in seeking consent from village collectives and original contractor as well as the great difficulty in finding appropriate undertakers. The third is that the collective ownership in the separation of three rights is not fully reflected, and it is likely to be left untouched.

3.2 The implementation of pilot reform of homestead (rural housing) and the confirmation and registration of rights are difficult

At the beginning of 2015, Homestead pilots are launched in 15 regions. According to the data, 15 pilot areas have already pull out of more than 76,000 homesteads, covering an area of 59,000 mu, with more than 31,000 mortgages of housing property rights, and a total of more than 3.7 billion yuan in loans (Zhu Juan, 2017). In 2018, the reform of homestead proposed "the separation of three rights", that is, homestead ownership rights, qualification rights, and the right to useMore complete empowerment of the homestead is conducive not only to homestead entering the market, but also to the realization of the mortgage and guarantee of homestead as well as the capitalization of homestead resources.

In the trial reform of homestead in various places, there are some difficulties to varying degrees. First, it is difficult to solve the problems left over by history. In rural areas, "single household with multiple houses" and excessive usage is common and farmers have become accustomed to using the homestead "for free". However, the conformation and registration of rights requires farmers to return homestead excessively occupied or use them with charge and it will arouse farmers resistance. Therefore, governments' implementation of reforms is arduous in consideration of the stability. Second, the trading market of the transfer of the homestead is confined to the village collective, which cannot form an influential trading market and also causes seriously underestimated value of homestead. Third, there is a lack of uniform reference for the pricing of homestead pulling out with compensation. Due to the

absence of a mature trading market of homestead and market price of it, areas differ over the standards and valuation methods as well as the prices when determining the price of compensated pull-out of homestead. For example, in Ningguo, Anhui the subsidies are 40,000 yuan to 60,000 yuan per mu and for the part beyond, the subsidies are 20,000 yuan to 30,000 yuan per mu, while in Dianjiang, Chongqing, the subsidies are120,000 yuan per mu.

3.3 The scope of the implementation of collectively owned construction land entering the market at the same prices is narrow

With the large-scale urbanization in China, the supply of urban construction land is insufficient, which has also become an important reason for the rise in urban housing prices; at the same time, there are a large number of collective construction lands in rural areas that are idle due to institutional reasons. This is not conducive to the growth of a collective economy and the increase in farmers' income, but it is also detrimental to the free flow of rural land resources and the construction of a unified urban-rural land market. In the new era of new urbanization and rural vitalization, the reform of the rural construction land system has become a general trend. At the end of 2014, the reform of collectively owned rural profit-oriented construction land entering the market was carried out in 15 regions and later expanded to 33 pilot regions. Trial areas such as Deqing in Zhejiang and Zezhou County in Shanxi Province all achieved the marketization of collectively owned rural profit-oriented construction land. For example, Deqing first sold a village-level collectively owned profit-oriented construction land with an area of 20 mu at the price of 575,000 yuan per mu in the form of public bidding, auction, hanging out a shingle on September 8, 2015. During the three-year pilot period, Zezhou County completed a total of 14 cases of marketization of collectively owned rural profit-oriented construction land with 195.75 mu. To expand the use of collectively owned construction land, in August 2017, the Ministry of Land and Resources and the Ministry of Housing and Urban-Rural Development selected 13 cities including Beijing, Shanghai and Wuhan to conduct pilot projects and aimed to explore the construction of rules, mechanisms, services and supervision system of rental housing using collectively owned construction land.

There are still deficiencies in the reform of the marketization of collectively owned rural construction land despite major breakthroughs which have been made. First, the pilot scope is narrow. At present, pilot reforms have been carried out in only 33 regions and other regions are not authorized to reform. Furthermore, in terms of the types of land, only profit-oriented construction land can enter the market, while the construction land which is not profit-oriented has not yet obtained the qualification for entering the market. Second, the distribution mechanism of interest needs further optimization. The profit from the marketization of collectively owned rural construction land must be reasonably distributed among the state, collectives, and farmers. The distribution ratio among the three parties in each region is not the same and, in some areas, the income of the rural households is relatively small, leading to conflicts concerning interests among the three parties. The third is the lag in supervision after the collectively owned construction land is introduced into the market.

4 Conclusion

4.1 The implementation of "the separation of three rights" should be promoted

First, it is necessary to conduct in-depth study of the rights and empowerment of collective farmers, contract farmers and agribusiness providers and further clarify the boundary of rights of three rights and their relationship.The second is to strengthen the construction of trading market system of the transfer of rural property rights, support the establishment of professional and standardized trading organizations for rural property rights, encourage trading institutions to carry out business across administrative regions, promote the establishment of provincial-level trading institutions, and promote the transfer of land in a wider range of markets. The third is to fully grant the land management right functions of mortgage and guarantee as well as certificates for management or transaction and use the certificates as the mortgage to get financial assistance from financial institutions. It is also necessary for the central or local government to issue supportive policies to encourage financial institutions to carry out loan business regarding the mortgage of land management right, as well as make joint efforts with financial institutions to prevent relevant financial risks.

4.2 The pace of pilot reform of rural homestead should be quickened

The ultimate goal of deepening the reform of rural homestead system is to allow both rural housing to be traded freely as well as enter the market with the same rights and at the same prices as state-owned land and farmers to have the same full right to use housing and land (Zuo Chenming, 2016). First, the

confirmation and registration of rights of homestead should be accelerated. Historical traditions and rural citizens' autonomy should be respected. Each region should determine farmers' qualifications and the pull-out of excessively occupied homestead as well as standards of paid use based on actual conditions and give confirmation and registration of rights to homestead and rural housing meeting requirements. Second, methods to effectively use idle rural homestead and farmers' idle homestead should be explored. For example, rural collective economic organizations may use construction land conserved in the process of rural and homestead renovation to develop industries such as rural leisure and pension tourism, and rural integration of three industries by means of shareholding, joint ventures (Ye Xingqing,2018). Thirdly, the key to the establishment of the mechanism and method of compensated pull-out of homestead is to solve the problem of where money come from. Storage companies of homestead should be establishedat countylevel and make companies responsible for the collection and storage of homestead. Homestead collected and stored can be leased, developed, or reclaimed. Fourthly, homestead and rural housing use rights should be allowed to mortgage and guarantee so as to achieve the financing functions.

4.3 Collectively owned construction land entering the market at the same prices should be promoted

The first is to establish a reasonable income distribution mechanism of land value-added income. After comprehensively considering all the factors forming land value-added income and confirming the collecting ratio of adjustment fund of land value-added income, the distribution of land value-added income should favor the collectives and individuals, and gradually establish a mechanism for the distribution of land value-added income that takes account of the national, collective, and individual interests (Zhang Yinghong, 2016). The second is to research and explore the system of transfer from adjustment fund of land value-added income to taxes and fees. The adjustment fund is a temporary arrangement and the transfer from adjustment fund to taxes and fees can not only be legally based but also become a local stable tax type under the trend of normalization and institutionalization of collective construction land. The third is to include the rural construction land which is not profit-oriented in reform timely. Eastern developed provinces have more collectively owned rural profit-oriented construction land, while most of the rural areas in the central and western regions have no idle profit-oriented construction land.

Research on Innovative Model of Art Talents Cultivation under the Background of Cultural and Creative Industry

Ma Hongyu, Wang Yuanyuan
School of Art and Design, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: 375378355@qq.com, 114618389@qq.com)

Abstract: Art talents have been playing an important supporting role in the development of cultural and creative industries. With the continuous development of cultural and creative industries and the deepening of innovation driven strategy, the cultivation of art talents is facing many new problems. This paper, starting from the system concept, breaks through the limitations of the general art talent cultivation theory, combines the classification of art talents with the industrial demand, and constructs the classification and positioning mode of six types of art talents based on the main needs of upper, middle and lower reaches of the art industry, and puts forward the art talents innovative model of training from the aspects of cultivating input, cultivating host and cultivating objectives.
Key words: Art talents; Talent cultivation; Innovative model; Cultural creative industry

1 Introduction

The cultural and creative industry emphasizes the support and promotion of cultural and art on economy, which is the emerging economic form and green industry of many countries in the world. And the main manifestations of today's art are basically concentrated in the field of cultural and creative industry. Art is the source of the cultural creative industry which has an important value itself. On the chain of creative industries, talents are the most fundamental, critical and important factors (Qin Jia, 2012). In recent years, China has been vigorously developing cultural and creative industry. The competitiveness of cultural and creative industries is essentially the competition of artistic talents. Artistic talents Artistic talents support the development of cultural and creative industries in terms of intellectual resources, and provide a sustainable development for the cultural and creative industries. Therefore, the cultivation of art talents is one of the key factors in the development of this industry.

In the field of cultural creative industry, the cultivation of art talents in China has the problems such as not paying attention to creativity in training objectives, over-specialization in training model, and being too elite in the process of talent evaluation and so on. How can the cultivation of artistic talents adapt to the development needs of the current cultural and creative industry is a big question. Although there are some researches in the academic field, there are still a lack of discussion on the creative cultivation of art talents from the perspective from the macroscopic system of the art market and the market demand (Cao Hong and Yan Yanfei, 2016). The current art and social life are linked in many aspects. The creativity, planning, management, dissemination, criticism and information consultation in artistic activities have become an important part of art production (Nie Lijia, 2009). New art talents such as art finance talents, art brokers, etc., are the parts of the art talents cultivation model that cannot be ignored. Therefore, we need to reconsider the cultivation model of art talents from a more systematic perspective, combined with the needs of art industrial chain.

2 General Connotation and Classification of Art Talents

The art talents cultivating model is one of the most important measures for the implementation of art education. There are different education and talents cultivating models in one country or regions in the same or different times. Higher artistic talents cultivation has been sticking to the elite education model. With the development of cultural and creative industries, the talent cultivation model of traditional elite art education has not been able to meet the development of popular art education, and the art talent cultivation has been discussed from the perspective of cultural and creative industries and art industrialization is the demand for art market and social development (Tan Yaosheng, 2013).

The art communication technologies, production methods, and media carriers are changing under the impact of globalization and informationization, and this new situation has been brought new demands to the traditional art talents cultivation methods and art education model. From the perspective of art subjects, the scope of contemporary art covers a wide range, and the arts and technology, agriculture, enterprises and other aspects of it have become a "value-added" effect of various industries (Zhu Zongqing, 2013). The connotation of artistic talents, the definition of artistic talents, and the

classification of artistic talents need to be re-examined. This also is the research basis of innovative cultivating mechanism of art talents. There are many methods for the definition and classification of artistic talents. The specific classification methods and contents are as follows. (Table 1)

Table 1   Art Talents Classification Method and Connotation

Classification Method	The Specific Content
Two – points (Lin Wen, 2010)	Pure Art Talents, Applied Art Talents.
Two – points (Feng Jia, 2012)	Professional and technical Talents, Management Talents
Three-points (Lin Wen, 2010)	High-level art talents, Intermediate level artistic talents, Operation level art talents
Three-points (Tang Jia Lu and Hu Ying Sheng,2015)	Open design art talents, Design art theoretical talents, Design art practical talents
Four-points (Shu Xiaping, 2013)	Single-art art college model, Normal college art department model; Theoretical research training model, Comprehensive university art talent training model.
Four-points (Shu Xiaping, 2013)	Practical application type talents; talents with practical and creative leading, with theoretical teaching and skill teaching; purely theoretical research talents; talents with theory as leading and capable of practice
Five-points (Ye Zhonghai,2009)	Drama Talents, Music talents, film talents, Art talents, Dance talents
Five-points (Zhao Qinping, 2013)	Artistic creation talents, artistic performance talents, art theory talents, art education talents and artistic application talents.
Seven-points (Tan Yaosheng, 2013)	Artistic research talents, Art education and teaching talents, Artistic and technical talents, Applied art talents, Community art talents, Ethnic art talents, Regional art talents.

As can be seen from the above table, there are many methods of classifying art talents, but most of them are based on the attributes of art itself. From the perspective of cultural creativity, the diversification of the art market will inevitably require multi-layered art education, multidimensional knowledge structures, and complex cultivation of artistic talents. The types of talents needed in the cultural and creative industries need to have multiple knowledge in an interdisciplinary context. Both the ability and the organic combination of science and art, especially in the creative and applied aspects of digital art, are the essential qualities of composite art talents.

3 Innovative Classification and Cultivating Position of Art Talents

The art talents cultivation model refers to the cultivation of the art talent training model and the art talent education according to the specific training goals and requirements under the guidance of art education concepts and laws, and scientifically setting teaching content, curriculum system, management system, and goal evaluation system. It is more in line with the requirements of the country's cultural development strategy. Talent cultivation meets the needs of social development (Shu Xiaping, 2013).

From the perspective of market demand, there is a great demand for applied arts talents, especially digital art talents and cultural management talents (Lin Wen, 2010). A complete cultural and creative industry chain should include three parts: culture and art (source), creativity (middle reaches), and industry (end) (Zhu Zongqing, 2013). Art industry chain is divided into three parts and five links, namely, the upstream, middle and downstream parts. Education, creative creation, production and production, sales of exhibitions, and re-invention are five links.

Therefore, based on the types of talents summarized in the current classification of art talents collected and combined with the needs of talents in the cultural and creative industries, this article holds that it is necessary to cultivate six kinds of artistic talents, namely, art theory talents, artistic creative talents, art education talents, art management talents, art production talents, and art business talents. These six types of artistic talents do not have the ability to compete. They are the art talents that needed in the cultural and artistic creative industries. However, the six types of talents play different values in different stages of development and different aspects of the art industrial chain. (See Figure 1)

According to the main axis of the art industry chain and the six types of art talents to discuss different kinds of artistic talent in the arts industry chain of upstream, midstream and downstream's value degree of strength, to construct an art industry developing different types of talents cultivation mode and direction.

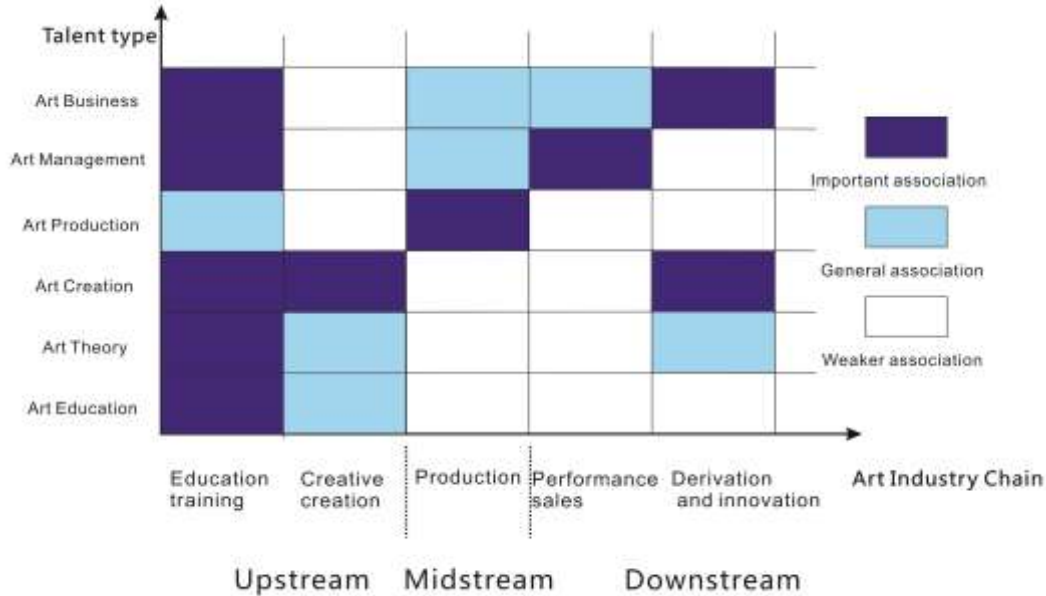
Distinguish the strengths and weaknesses of the six types of talents in the various aspects of the art industry chain, determine the structure of art talents training, and the types of industries associated with art talents, and give full play to the joint training of corporate resources, social resources, etc. This kind of transformation vision, with the art industry chain as the logic point art talent training model, has certain innovation value for changing the current art training system.


Figure 1   Artistic Talents Cultivation Model under the Art Industry Strategy

4 Innovative Cultivation Mechanism of Art Talents

Art talents cultivation model is a systematic study, involving many elements, as well as many subjects and levels, the implementation main body has a national policy formulation, there are also schools, enterprises, the implementation of public art field and so on. Therefore, we need to systematically design the cultivation of art talents, and explore the innovative mechanism of artistic talent cultivation.

The diversity of art categories, the complexity of the art system, and the diversity of artistic talents make it necessary for the cultivation of artistic talents to be advanced step by step. In the process of the art cultivation, the main body, including government policy levels, schools, enterprises, social art institutions and groups, work in coordination with each other to coordinate the cultivation of artistic talents. The input includes: teachers, funds, and platforms; the integration of the four main subjects in the training of artistic talents: government, enterprises, schools, and other social resources such as art galleries, museums, social art groups, etc. The process has different values and meanings. For example, the government elaborates on the country's macroeconomic policy formulation, the orientation of personnel training, capital investment, and the establishment of art talents fundraising projects, etc., and provides relevant departments with constructive opinions and countermeasures. (See Figure 2)

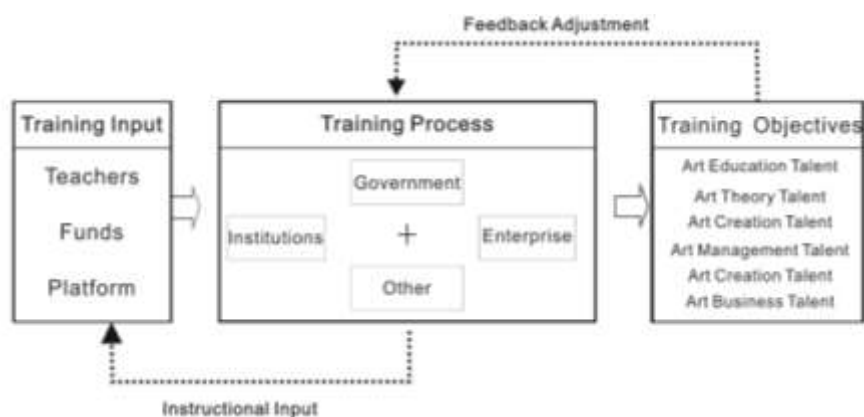
Through a combination of the above factors, in order to achieve the basic goals of the six types of art theory talents, artistic creative talents, art education talents, art management talents, art production talents, and art business talents. In addition, the improvement of the quality of art talents should be based on the needs of society and art talents of different location to be layered, classification, establish the evaluation system.


Figure 2   Artistic Talents Cultivation Model under the Art Industry Strategy

5 Conclusion

This article examines the cultivation of talents in China as a whole and systematically. It combines the cultivation of art talents with the current social and economic development in China, and explores the direction of the cultivation of art talents in a rational way. From the macro perspective, we will explore the mechanisms and paths for the cultivation of various types of artistic talents that are suitable for the current economic development situation, and explore the top-level design patterns and dynamic research systems for the cultivation of art talents.

Abstract：Scientific and technological innovation culture is a kind of good innovation atmosphere, which is the basic soil for cultivating innovative talents, cultivating new technological achievements and forming new technology industry chain.Good college scientific and technological innovation culture can let related subjects acquire the consciousness of independent innovation, regard scientific and technological innovation as an inner needs and spiritual motivation.It is conducive to improve subject's scientific and technological innovation capability.Colleges and universities are important generations of scientific and technological innovation achievements.This paper systematically sums and combs the way of cultivate college scientific and technological innovation culture, additionally, it puts forward innovative cultivating way on the basis of empirical research.
Key Words: College scientific and technological innovation culture; The way of cultivate; Technological innovation; Wuhan university of technology

1 Introduction

College student is an important subject of scientific and technological innovation.Putting them into the scientific and technological innovation culture attribute to cultivate their scientific and technological innovation capability and the develop their technological innovation potential.Problems lie in the process of cultivating college scientific and technological innovation culture, such as campus atmosphere of technological innovation is not strong, the system of the school management is imperfect, tutors are not very enthusiastic, the tutor team of scientific and technological innovation activities is imperfect.

2 Research Status at Home and Abroad

At present, both domestic and overseas research on the important subject of college scientific and technological innovation culture cultivation.

2.1 Overseas research status

At present, the Overseas research results of foreign universities' scientific and technological innovation culture are mainly concerned about various cultivation modes.Harvard University graduate school has adopted "science and technology, innovation and education program", and use it as a way of training creativity and execution as well as evaluation many items such as education, science and technology media capable leader. Its objects include all students and faculty.The "technology, innovation, education program" integrate science and technology into teaching methods to provide the most effective teaching experience and to enable outstanding students from around the world to learn from each other.The learning content includes: how to investigate and design a new technology product, and use technology and media to improve the immersing learning experience. The class project let students make the prototype of cutting-edge technology products, and the whole process is equipped with the guidance of top practitioners or relevant teachers.But technology is only a means of breeding, not an end.The choice of adding media or cutting-edge technology into the teaching is aimed at improving learning efficiency.This program does not require students to have prior experience in computer science and technology, and only requires students to be enthusiastic about innovation.

Franklin W. Olin College of Engineering offers many courses based on project cooperation.Unlike most engineering courses, this school chose appropriate and targeted education content, and the curriculum is an amalgam of feasibility, viability, desirable, especially attaches great importance to the cultivation of innovation ability.Innovative skills include creative thinking, effective reasoning, convergence and divergent thinking, and behavioral responses. Focusing on developing individuals who are self-directed, confident, and motivated by their sources.

2.2 Domestic research status

The importance of scientific and technological innovation culture.Tang Genli believes that cultivating college students' innovation and entrepreneurship ability is a major strategic measure to serve the construction of innovation-oriented country. It is an important way of cultivating students' innovative spirit and practical ability.It is an important measure to implement entrepreneurship to promote employment and promote the full employment of college graduates.

Research on the influencing factors of the cultivation of scientific and technological innovation culture in colleges and universities.Many scholars believe that the country's policies and strategies are essential strength and correct guidance to promote the innovation of scientific and technological culture in colleges and universities.As Yang Yu pointed out, the country's "12th five-year" science and technology development planning, on the development of the business and promote the innovation in the public space of the guidance, the state council on pushing through public entrepreneurship people's opinions on some policies and measures of innovation such policies raised a storm of innovation entrepreneurship.Wang Shouguan pointed out that the promotion of mass entrepreneurship and innovation requires institutional innovation and better scientific spirit. Jiang Xiaodong believes that the spirit of innovation is an important part of the scientific spirit, which is an important foundation for innovation and a spiritual source of all innovation and creation.

Research on the way of cultivate college scientific and technological innovation culture.Yang Yu claim on constructing the education system of innovation and entrepreneurship for college students, putting innovation entrepreneurship into the teaching system, constructing college students' innovative undertaking education practice base, establishing diversified creative teachers, etc.Wang Xiaoming advocates the construction of the university's maker space to cultivate students' innovative ability.In order to reform the traditional education mode, we will add innovative content to the curriculum.Creating an atmosphere of innovation in colleges and universities, reforming the teacher evaluation system and the student evaluation system, attaching importance to the student's personality development, the innovation ability and the comprehensive ability evaluation, based on which builds the student's comprehensive evaluation system.Cao Huiqiu believes that the cultural system of colleges and universities should be innovated, the investment in materials should be increased, the teaching facilities such as new media should be popularized,cultivate students' innovation driving force in students should be attached importance to, innovative knowledge system should be constructed. JinYongcan proposed to cultivate innovative teachers, implement personalized education, reform the employment system and other paths.

On the basis of relevant research theories, many colleges and universities have established their own scientific and technological innovation culture.Fudan university teaches students basic knowledge and basic skills of entrepreneurship, East China Normal University tries to open a"entrepreneurial education curriculum", Wuhan University carries out the "three innovate"education, the institution such as the science institution of Beihang University support student entrepreneurship with capital support.In recent years, three typical education modes have been formed: The subject oriented mode represented by Renmin University of China; The practice-oriented model represented by Beihang University; Comprehensive model represented by Shanghai Jiao Tong University.

3 The Cultivation of Science and Technology Innovation Culture in Universities: A Case Study of Wuhan University of Technology

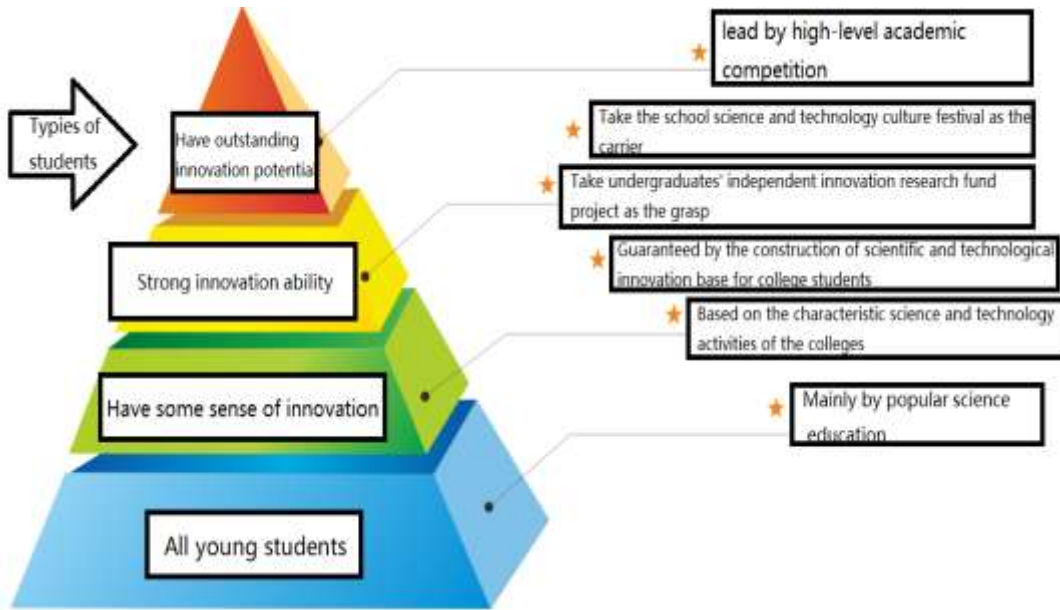
Basing on our aim to build a culture of innovation in science and technology for university students and cultivate top-notch innovative scientific research talents, Wuhan University of Technology provides students a wonderful platform of innovation, and enhance students' innovation ability through lectures, students projects and academic competitions.And our university holds academic lectures and conference and other activities, particularly from the basic level of awakening scientific consciousness and training of scientific research.At the same time, academic societies which make full use of features have played an important role in cultivating students' comprehensive innovation abilities.Our university also sticks to focus on scientific and technological activities , "Innovative Cup" science and technology festival has become a unique brand.


Figure 1   The Independent Innovation "Climbing Action"of Science and Technology Culture System in Wuhan University of Technology

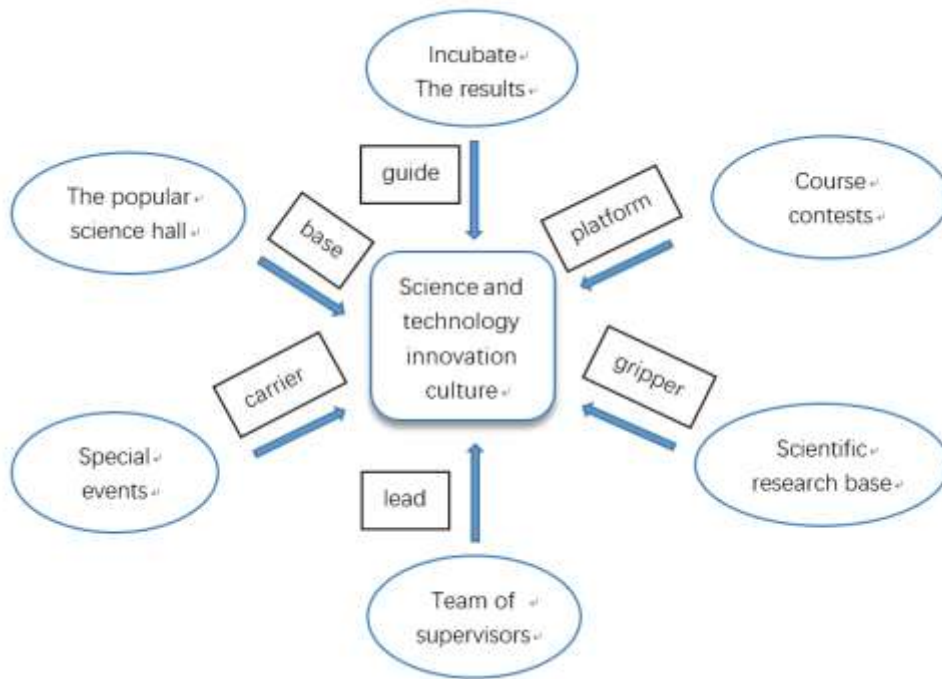
Through questionnaires and visits, combined the result with the specific situation of Wuhan University of Technology and other domestic universities, we can see that although each school has invested a lot of energy into building a scientific and technological innovation culture as well as introduced relevant policies, which did have been realized certain achievements, there are still some deficiencies of scientific and technological innovation activities done by university students now.


Figure 2   University "Six Wheel Drive" Scientificand Technological Innovation Culture System

First of all, the school innovation atmosphere and management system are not perfect. According to the results of the questionnaire survey in our University, about 20% of the students think that the technological innovation support policy and the school innovation atmosphere are general when others

feel satisfied. Secondly, the motivation of the academic advisors is still low, the faculties of scientific and technological innovation activities advisor team are also not completed yet. As we can see from the questionnaire survey in the whole, in the terms of giving guidance to student's innovation activities, there still remains biggish demand of the quality advisor teams. What's more, we also have found some problems that have greatly limited the development and improvement of scientific and technological innovation activities, such as imperfections in the system of school guarantees, unbalanced development of innovation activities, and low quality of achievements.

And then, analyzing the causes for the problems in the cultivation of scientific and technological innovation activities. First, at the school level, the policy support, school innovation cultural atmosphere and management system need to be consummated. It is obvious that the innovation atmosphere, the cultivation of innovative thinking, and practical professional guidance are insufficient. Moreover, the lack of personal expertise and support in the material level also becomes the barrier to scientific and technological innovation activities in our university. Second, at the teacher level, some teachers' awareness is not comprehensive enough. They believe that the first classroom education is superior to the second classroom education and neglect the guidance of students. Some teachers who are busy with their own teaching and research work have little enthusiasm for guiding students' scientific and technological innovation activities, which has led to these activities can't be carried out in depth. Third, at the student level, many students' theoretical knowledge and foundations are not solid, ignoring the accumulation of knowledge except the major. And there are also students who study passively. In addition, the important reason for the unbalanced development of students' scientific and technological innovation activities is the unbalanced development of disciplines. From the survey results, students have trouble in lacking hands-on ability, teacher's guidance and funds in the process of innovation, regarding their narrow knowledge and short of good ideas as the main one.

4 Analysis of the Cultivation of Scientific and Technological Innovation Culture in Universities

Through the questionnaire survey on the students of Wuhan University of Technology and the visit to other domestic colleges and universities, the related materials and the problems of the scientific and technological innovation activities of the college students are summarized. It can be found that the educational function of college education, on the basis of taming the theoretical knowledge in the first classroom teaching, we should attach importance to and strengthen the expansion and extension of the second classroom, improve the students' comprehensive quality through various scientific research projects and practical training methods, and realize the function of educating people in colleges and universities.

4.1 Use characteristic activities as a carrier to enhance the campus science and technology innovation atmosphere

Schools should vigorously advocate campus culture with the theme of scientific and technological innovation, and form a popular and innovative campus atmosphere. By inviting experts and scholars from relevant fields to school, holding regular academicians' forums, scholars' forums, and other series of popular science lectures, aiming at frontier development of science and technology and social needs, encouraging ordinary students to participate in various research projects and discipline competitions, listening to various academic reports, we will deepen the concept of scientific and technological innovation into the minds of every ordinary students, and enable the scientific and technological innovation to form a new situation of national participation, no longer just a game of the minority.

Schools should rely on professionalism, give full play to their advantages, and constantly improve the innovative, entrepreneurial and educative endurance of scientific and technological activities with academic characteristics. Schools should encourage academies to carry out branded academic and scientific and technological cultural activities with distinctive disciplinary characteristics combined with professional characteristics, and gradually form a good situation of scientific and technological innovation of "one academy, one festive, one feature". These scientific and technological and cultural activities with strong disciplinary characteristics are based on the characteristics of the academic disciplines and are geared towards the most extensive student groups in the whole school, which have a positive role in encouraging students to actively engage in innovative entrepreneurial practices, expanding projects, exploring talents, cultivating a group of students with strong innovative abilities and promoting the atmosphere of students' innovation and entrepreneurship, and are conducive to the formation of a new situation of campus science and technology innovation activities like "a hundred

flowers bloom, strive for beauty".

Schools should guide and set up a number of innovative science and technology societies and research bases, such as the Student Science and Technology Association, the Excellent Innovation Base, etc. Science and technology innovation base is an important position of cultivating students' innovative spirit. It has strong professionalism, it can better combine the characteristics of professional knowledge, cultivating students' good sense of innovation and innovation ability. By organizing disciplinary competitions, students can better understand the core connotation of the competition, and they can also increase their interest in the application and experience of professional knowledge, thus making the activities of science and technology innovation become a kind of campus culture. Through carrying out practical training of various innovative projects, students' innovative thinking and practical ability can be further improved, so that students can really participate in all kinds of scientific research projects.

4.2 Take the mentor team as the guide and perfect the security system

Judging from the results of the survey visits, most university students' scientific and technological innovation activities currently have unstable scientific research teams, poor communication, and inadequate teacher guidance. The school should train teachers, introduce a group of excellent and high-quality teachers who are willing to study with students and have high academic accomplishments, and strengthen the professional level of teachers. On the basis of years of practice, schools should further improve the relevant assessment system for instructors, establish a reasonable management system, and establish a perfect guarantee system for scientific and technological innovation activities. This guarantee system should include a strong executive force, a stable management organization, the guidance of the teacher's organization and a good training system. It should also include supporting financial support, site support, and policy support, etc.

In addition, in response to the low enthusiasm of instructors, a corresponding assessment and reward system for instructors should be established. The teacher's guidance of students in the technological innovation work is linked with the teacher's annual assessment and promotion. At the same time, the teachers who have achieved the results are given a certain amount of spiritual rewards and material rewards, so that the university students can receive comprehensive guidance in scientific and technological innovation, and can also make Students' ideas are translated into actual works more easily. At the same time, the school is equipped with tutors for undergraduates, deepens the tutorial system, and strives to build a tutor team with a high level of theory and practice.

Take the discipline competition as the platform to show the students' demeanor Schools should rely on the holding of high-level scientific and technological competitions to encourage students to meet challenges, practice boldly and be good at innovation and effectively promote students' ability of independent innovation. Schools shall adhere to the "Challenge Cup" National Competition for College Students' Extracurricular Academic and Scientific and Technological Works, the "Youth creation" National College Student Entrepreneur Competition, the "Energy Saving and Emission Reduction" Social Practice and the Scientific and Technological Works Competition, the Mechanical Innovation Design Competition and other kinds of state-level competitions and actively organize students to participate in various high-level competitions, including the Logistics Design Competition, the College Students' Electronic Design Competition, the Transportation Science and Technology Competition and so on. Schools rely on the competition activities with the characteristics of specialized disciplines, form the academic competition pattern which integrates point and sphere, and strive for outstanding achievements in all kinds of major competitions. Schools have cultivated a group of students as advanced and typical characters of innovation and entrepreneurship, and have also encouraged more students to actively throw themselves into the practice of innovation and entrepreneurship, and to highlight the fruitful results of innovation and entrepreneurship practice.

Based on the results of incubation, promote the production of students' works Schools should rely on the characteristics of disciplines, strengthen cooperation with enterprises in the industry and government departments, make use of school brands, rely on alumni resources, and strive for government policy support and financial support from alumni enterprises to promote the transformation of students' works from the state of laboratory to products, and to further the students' achievements to be applied to the production practice of enterprises and society.

Through the analysis of the investigation report above, we preliminarily explore the path of university students' science and technology innovation culture cultivation, put great efforts into perfecting the first class education system, improve the quality of education, compact the theoretical foundation and provide theoretical support for students to participate in scientific and technological innovation activities. we make efforts to build the "six-wheel drive" science and technology innovation

culture system which takes science popularization lectures as the foundation, characteristic activities as the carrier, mentor teams as the guide, scientific research bases as the grasp, scientific research projects as the platform, and achievements hatching as the direction, create the second class of students with characteristics, and really facilitate the development of scientific and technological innovation activities of college students into the fast lane.

5 Conclusion

On the basis of summarizing the present situation of scientific and technological innovation culture cultivation in universities at home and abroad, taking Wuhan University of Technology and other famous universities as key research objects by issuing online and offline questionnaires,

This article summarizes the existing problems in the cultivation of scientific and technological innovation culture in colleges and universities, and finally puts forward the specific ways of cultivating scientific and technological innovation culture in colleges and universities, such as building the "six-wheel drive" science and technology innovation culture system which takes science popularization lectures as the foundation, characteristic activities as the carrier, tutor teams as the guide, scientific research bases as the grasp, scientific research projects as the platform, and achievements hatching as the direction. This path contributes to promoting the further development of scientific and technological innovation activities of college students, makes the scientific and technological innovation activities of college students step into a good track and strengthens the construction of scientific and technological innovation culture cultivation in colleges and universities.

Research on Financial Competitiveness of High-end Equipment Manufacture Industry in China: Based on Factor Analysis

Li Yu

School of Management, Wuhan University of Technology, Wuhan, P.R. China, 430070

(Email: 1875409972@qq.com)

Abstract: This paper has collected and sorted out panel data of 79 high-end equipment manufacture A-share listed companies in Shanghai and Shenzhen from 2014 to 2016 for factor analysis by applying Stata software and has extracted three main factors of debt paying ability, profitability and debt paying ability by dimensionality reduction. This paper has constructed regression equation of financial competiveness, calculated total score and implemented ranking. Research result shows: the whole financial competiveness of high-end equipment manufacture industry is relatively strong, but development among enterprises is unbalanced. By putting forward attention to national policy of enterprises with not strong financial competiveness, increasing investment in scientific research and strengthening suggestion of international communication and cooperation, development of high-end equipment manufacture industry will march toward a new step.

Key words: High-end equipment manufacture industry; Financial competitiveness; Factor analysis; System dynamics model

1 Introduction

In 2017, General Secretary Xi proposed in report of the 19th National Congress of the Communist Party of China of the Party to accelerate establishment of strong manufacture country and accelerate development of advanced manufacture industry. In 2015, the State Council issued Made in China 2025, which provided action outline for China to implement strong manufacture country. In 2016, executive meeting of the State Council passed Equipment Manufacture Industry Standardization and Quality Promotion Planning. Manufacture industry is core force to develop national economy, but high-end equipment manufacture industry with high technology and high additional value is its core (Jing Yongsheng, 2014). In addition, it is very necessary to enlarge attention degree and support strength to financial competitiveness of high-end equipment manufacture industry. High-end equipment manufacture industry involves aviation industry, satellite, application industry, railway transportation equipment industry ocean engineering equipment and intelligent manufacture equipment fields. In recent years, establishment of Tiangong-2 laboratory, normal operation of Fuxing CRH train and successful maiden flight of national large flight C919 all embody promotion of whole level of national high-end equipment manufacture industry.

Because the high-end equipment manufacturing industry is a newly developed industry in recent years, most of the research has contributed to the development of the industry based on technology, and few scholars have studied the financial competitiveness of the industry. The innovation of this paper is that the study of the industry is based on the perspective of financial competitiveness.

This Paper has selected 9 financial indexes of high-end equipment manufacture enterprises represent its financial competitiveness level (Song Xiaoling, Du Meijie, Liu Shasha, 2016) and classified them, to calculate comprehensive score of financial competitiveness of different enterprises and clarify difference of its financial competitiveness among different enterprises, which aims at putting forward some suggestions for future development of enterprise in disadvantageous status and promoting whole competitiveness of high-end equipment manufacture industry in China.

2 Factor Analysis of Financial Competitiveness of High-end Equipment Manufacture Industry

2.1 Data source

This Paper collects and sorts out index data of panel finance from 2014 to 2016 (Liu Chunying, Yu Qingqing, 2013) by taking 89 high-end-equipment manufacture enterprises as research objects and utilizing CSMAR, Straight Flush Finance Website and Sina Finance Website. To ensure completeness and comparability of data, 5 ST companies and 5 companies with incomplete information data are eliminated and 79 companies are obtained as sample.

2.2 Model construction

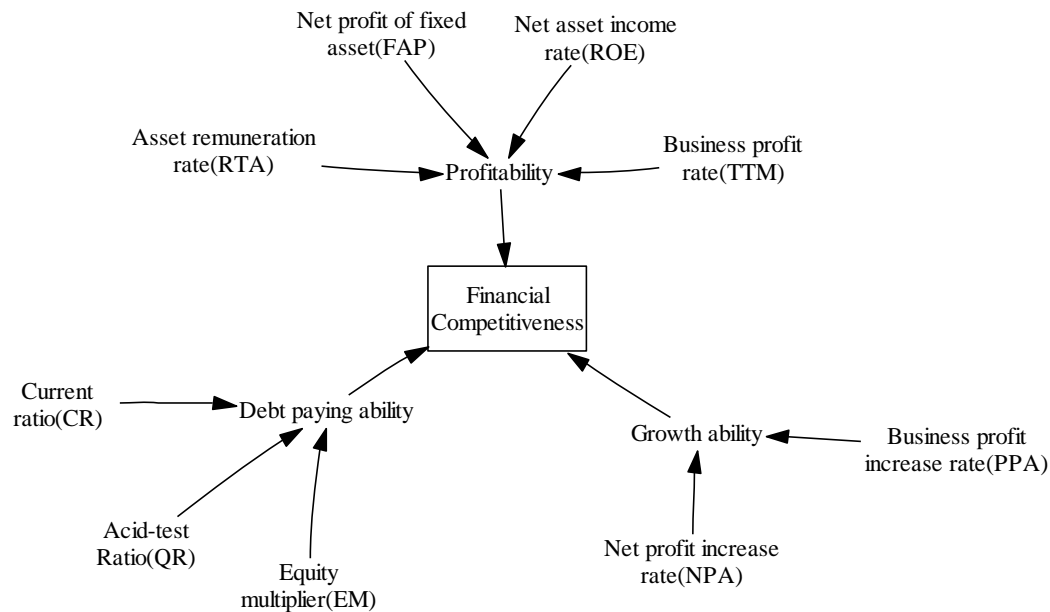
This Paper implements factor analysis by utilizing Stata statistics analysis software and transforms several correlative financial index data into several independent comprehensive indexes by dimensionality reduction. The purpose is to interpret more variables with a few variables and simply complex problems. According to principle of factor analysis, this Paper standardizes variable, calculates correlative matrix, implements KMO inspection and deducts main factor (Li Shuangshuang, 2015). To increase feasibility and persuasion of living examples, this Paper implements empirical analysis by adopting average value of ending financial data from 2014 to 2016 (He Shan, 2016). Influence of change condition of all financial indexes on financial competitiveness can be reflected intuitively by applying system dynamics Vensim software, as shown in Figure 1.


Figure 1　System Dynamics Model of Finance Competitiveness

2.2.1 Analysis on descriptive statistics quantity

Table 1 lists the maximum, the minimum, mean value, variance and standard deviation coefficient of 9 financial indexes of 79 high-end equipment enterprises. The maximum and the minimum reflect extreme value condition of value distribution within definition interval; Mean value reflects average level of corresponding variables; standard difference reflects dispersion degree of corresponding variable value distribution. Standard deviation of asset remuneration rate is the minimal, which shows that its value distribution is relatively concentrated. Standard deviation of increase rate of net profit is the maximal, which shows that its value distribution is relatively loose and difference of increase speed of net profit in different high-end equipment manufacture industry is relatively large-,the growth rate is different. Standard deviation coefficient is equal to ratio of standard deviation and mean value and reflects absolute value of data disperse degree under different conditions of data dimension. The index value of businessprofit growth rate is the maximal, which shows that difference of business profit increase speed of different high-end equipment manufacture enterprises is relatively large.The growth of each enterprise is uneven.

Table 1　Descriptive statistics

	Minimum	Maximum	Mean	Variance	Coefficient of Variance
CR	.6701	8.1267	1.989226	1.3383879	0.581576533
QR	.4452	6.9806	1.497464	1.1626411	0.720056285
EM	1.0901	5.7953	2.268031	.9335217	0.426003554
NPA	-28.2358	110.6017	1.081458	13.6751540	3.419451555
PPA	-45.4835	69.9143	.479708	11.9835710	7.216326351
RTA	-.0369	.1312	.028251	.0297104	6.101272529
FAP	-.1675	.9919	.163490	.2356742	2.96937349
ROE	-.2837	.1535	.033640	.0686514	7.788766996
TTM'	-.2442	.3390	.036516	.1030248	8.789976048

2.2.2 Correlation analysis

To unify standard deviation with data unit 1, this Paper standardizes data and mean value of data after standardization is 0 and standard deviation is 1. Standardized data are adopted in the following paper. Correlation matrix has described intensity of correlation among variables. It can be obtained from data in Table 2 that correlation coefficient between ZCR and ZQR is 0.978; correlation coefficient between ZRTA and ZTTM is 0.821 and correlation coefficient between ZROE and ZTTM is 0.762 and corresponding sig value is all .000, which shows that correlation among the three couple of variables is very significant. They are proper for factor analysis.

Table 2   Correlation Matrix

	ZCR	ZQR	ZEM	ZNPA	ZPPA	ZRTA	ZFAP	ZROE	ZTTM
ZCR	1.000	.978	-.552	-.127	.003	.309	.339	.243	.360
ZQR	.978	1.000	-.549	-.115	-.032	.352	.366	.272	.390
ZEM	-.552	-.549	1.000	.076	-.151	-.325	-.259	-.335	-.355
ZNPA	-.127	-.115	.076	1.000	-.064	-.099	-.097	-.101	-.191
ZPPA	.003	-.032	-.151	-0.064	1.000	-.014	.010	.107	.015
ZRTA	.309	.352	-.325	-.099	-.014	1.000	.739	.856	.821
ZFAP'	.339	.366	-.259	-.097	.010	.739	1.000	.709	.734
ZROE	.243	.272	-.335	-.101	.107	.856	.709	1.000	.762
ZTTM	.360	.390	-.355	-.191	.015	.821	.734	.762	1.000

2.2.3 Factor analysis

Based on correlation matrix analysis, factor analysis is further implemented. Under general condition, value of KMO is larger than 0.7, which shows that it is proper for factor analysis. As shown in data in Table 3, value of KMO is 0.7779, which is larger than critical value, which shows that data in this Paper are proper for factor analysis.

Table 3   KMO

Variable	KMO
Current Ratio	0.6154
Acid-test Ratio	0.6199
Equity Multiplier	0.9329
Net profit growth rate	0.6639
Sales profit growth rate	0.2291
Return on Total Assets Ratio	0.8093
Net Profit of fixed asses	0.9263
Rate of Return on Common Stockholders' Equity	0.8323
Operating Profit Ratio	0.8863
Overall	0.7779

Characteristic value and accumulated variance contribution rate in Table 4 and characteristic value and accumulated variance contribution rate after rotation of Table 5 have listed variance strength and accumulated total variance of each common factor interpretation. Seen from characteristic value column that principle of common factor withdrawal is that characteristic value is larger than 1. Therefore, we have selected three factors and accumulated variance sum has reached 76.050% and can better represent most data information better.

Table 4   Eigenvalues and Total Variance Explained

Factor	Eigenvalues	Proportion	Cumulative
Factor1	4.107	0.45636	0.45636
Factor2	1.662	0.18469	0.64105
Factor3	1.075	0.11945	0.76050

Table 5   Rotated Eigenvalues and Total Variance

Factor	Eigenvalues	Proportion	Cumulative
Factor1	3.293	0.36584	0.36584
Factor2	2.432	0.27021	0.63605
Factor3	1.120	0.12444	0.76050

Table 6 shows component scoring coefficient matrix. It has displayed factor load of all factors by data intuitionally and has clarified load distribution of three factors. It can be got by weighing load distribution of 3 factors on various variables that factor 1 occupies larger load on RTA, FAP, ROE and TTM; factor 2 occupies relatively large load on CR, QR and EM; factor 3 occupies relatively large load on NPA and PPA.

Table 6   Component Score Coefficient Matrix

Variable	Factor1	Factor2	Factor3
ZCR	-.098	.444	-.054
ZQR	-.080	.435	-.090
ZEM	.051	-.286	-.202
ZNPA	.011	-.015	-.407
ZRTA	.309	-.067	-.055
ZPPA	-.064	-.061	.831
ZFAP	.277	-.042	-.059
ZROE	.305	-.106	.074
ZTTM	.277	-.032	.006

By summarizing component scoring coefficient matrix in Table 6 and rotation component matrix in Table 7, all index variables can be classified as follows: ZRTA, ZFAP, ZROE and ZTTM are taken as the first main factor; ZCR, ZQR and ZEM are taken as the second main factor and ZNPA and ZPPA are taken as the third main factor.

Table 7   Rotated Component Matrix

Variable	Factor1	Factor2	Factor3
ZCR	.158	.957	.007
ZQR	.198	.950	-.030
ZEM	-.213	-.683	-.273
ZNPA	-.100	-.111	-.456
ZRTA	.927	.172	.016
ZPPA	-.035	-.041	.898
ZFAP	.847	.196	.006
ZROE	.906	.101	.150
ZTTM	.879	.235	.081

By summarizing foresaid KMO inspection table, characteristic value and accumulated variance contribution rate table, rotation component matrix and rotation space component diagram, all financial variable indexes are classified into three main factors. The first main factor occupies relatively large load on asset remuneration rate, net profit of fixed asset, net asset income rate and business profit rate, which is divided into profitability index. The second main factor occupies relatively large load on current ratio, quick ratio and equity multiplier , which is divided into debt paying ability index. The third main factor occupies relatively large load on net profit increase rate and business profit increase rate, which is divided into growth ability index. See Table 8 for specific classification of all variables indexes.

Table 8　Index Summary

Index	Variable
Profitability index	RTA（Asset remuneration rate）
	FAP（Net profit of fixed asset）
	ROE（Net asset income rate）
	TTM（Business profit rate）
Debt paying ability index	CR（Current ratio）
	QR（Acid-test ratio ）
	EM（Equity multiplier）
Growth ability index	NPA（Net profit increase rate）
	PPA（Business profit increase rate）

3 Results

By combining with three indexes, comprehensive score of financial competitiveness of high-end equipment manufacture enterprise is calculated and its evidence formula is: According to final score, total score of 79 high-end equipment manufacture industry is ranked from front to back. To summarize average level and individual difference comprehensively, this Paper selects enterprises, of which total scores rank in the top 5 and bottom 5 and list scores in two intervals. The first interval represents enterprise, of which total final score ranks top 5 and the second interval represents enterprise, of which total final score ranks bottom 5. See Table 9 for specific ranking condition of total score and all components. Ranking of component 1, component 2 and component 3 of enterprises with total score ranking in bottom 5 is relatively low. When all component scores are relatively low, according to calculation formula of total score, total score is naturally low. Ranking of enterprise component 3 with total score ranking in the top 5 is relatively low. After exploration, it is found out that the enterprise has existed for relatively long time in the industry and its growth space is relatively less than newly-rising enterprises in the industry. Total score of enterprise that ranks the first is 1.61 and shares are briefly called as Sanlux. Net asset income rate of the Company increases continuously recently, which shows that its profitability is favorable. Total score of enterprises that rank in the last is -1.27 and shares are called briefly as Taiyuan Heavy Industry. Year-on-year growth of business income of the Company decreases obviously recently, which shows that its profit condition is unstable. It can be seen that main component score of high-end equipment manufacture enterprises is relatively large, which has showed that difference of financial competitiveness of different high-end equipment manufacture enterprises is relatively large.

Table 9　Main Component Scoring List of Part of High-end Equipment Manufacture Enterprises

Share code	Total score ranking	Total score	Component 1 ranking	Component 2 ranking	Component 3 ranking
002224	1	1.61	6	2	74
300024	2	1.03	4	5	66
300384	3	1.00	1	16	61
002270	4	.86	7	7	72
002651	5	.85	8	6	56
000680	75	-.69	77	40	39
000852	76	-.72	78	47	43
002535	77	-.91	64	58	78
600760	78	-1.21	79	62	73
600169	79	-1.27	71	76	79

4 Robustness Test

This Paper implement robustness test by data substitution. Data selected in factor analysis of this Paper are average value of panel data from 2014 to 2016 and are replaced with panel data in the end of three years from 2014 to 2016 and selected financial variable indexes are unchanged. Factor analysis for

3 times has been implemented by SPSS statistical software. Experiment result shows that three main factors of debt paying ability, profitability and growth ability are obtained by dimensionality reduction and scoring order of all enterprises is ranked according to total score of main component. Except for relatively large change in financial competitiveness in enterprises with comprehensive ranking No. 3 and No.4 in 2011 for inner reason, there is no significant change in ranking order of rest enterprises, which shows that result of this Paper is stable. Table 10 is ranking order list of enterprises with ranking top 5 and ranking bottom 5.

Table 10   Main Component Total Scoring Ranking List of Part of Enterprises

Share code	Ranking	Ranking in 2011	Ranking in 2012	Ranking in 2013	Average ranking
002224	1	1	2	1	1.33
300024	2	4	3	3	3.33
300384	3	75	4	4	27.67
002270	4	28	1	2	10.33
002651	5	2	6	7	5
000680	75	68	76	62	68.67
000852	76	38	61	78	59
002535	77	60	77	51	62.67
600760	78	73	79	53	68.33
600169	79	74	74	79	75.67

5 Conclusion

This paper has implemented factor analysis on liquidity ratio, quick ratio, equity multiplier, return on assets, net profit of fixed asset, net assets income rate, operating profit ratio, net profit growth rate and business profit increase rate of 79 high-end equipment manufacture enterprises and classifies it into three main factors and calculates its comprehensive score of its financial competitiveness finally. It is found out by empirical study result that whole financial competitiveness of high-end equipment manufacture industry is relatively strong, but strength of different enterprises is different and competitiveness level difference is relatively large.This is in agreement with the conclusions of the relevant scholars (Huang Minyi, 2015) For enterprises with relatively lower score in financial competitiveness score, this Paper puts forward the following three suggestions. (I) Strengthen attention to relevant national policy. National policy is compass of industry development and the country pays highly attention and supports greatly for strategic emerging industry, such as high-end equipment manufacture industry. High-end equipment enterprises shall seize opportunity and develop rapidly under guidance of national policy. (II) Enlarge investment to scientific research innovation. Because of inherent characteristics of high-end equipment manufacture industry of high technology and high value, requirement to scientific innovation is very high. Increase of investment in scientific innovation is embodied in introduction and cultivation of scientific talents and construction and maintenance to infrastructure. Only through continuous innovation in scientific research, can we keep up with the times and meet the needs of the people. (III) Strengthen international communication and cooperation. Under driving of"The Belt and Road Initiative", communication and cooperation of China with other countries are increasingly frequent. High-end equipment manufacture industry of China can "bring in and go out", learn mutual experience, create international brand and increase influence under tide of the age. Under large environment of quick economic increase, we expect to highlight competition advantage of high-end equipment manufacture enterprise and different enterprises can keep pace with each other jointly and facilitate development of high-end equipment manufacture industry in China and even development of the whole manufacture industry.

Research on Innovation-driven Development Strategy, Comparative Advantage and Industrial Transformation and Upgrading

Lu Songnan
Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: 309305706@qq.com)

Abstract: China is in the midst of a momentous economic transition from one of high-speed to high-quality growth. The industrial transformation and upgrading supported by extensive growth model that focused on "quantity" has encountered bottlenecks. It's urgent to find a new model to promote new round of industrial transformation and upgrading. This paper, based on the current unbalanced industrial structure in China, analyzes the development strategy China has implemented since reform and opening up and its influence on industries. Conclusions are as follows: China has implemented an extensive forging ahead growth strategy that transcends comparative advantage. This has generated industrial structure deviations, longstanding factor price distortion, overcapacity and wave phenomenon and constrained industrial transformation and upgrading. Therefore, China should choose an innovation-driven development strategy that could unleash the potential of comparative advantage and drive industrial transformation and upgrading.
Key words: Innovation-driven development; Comparative advantage; Industrial transformation and upgrading

1 Introduction

Industry is the bedrock of economic growth and industrial structure holds the key to sustained economic growth. Since the outbreak of the global financial crisis in 2007, China's central and local governments have pressed ahead with industrial structural reform at a higher speed. However, problemssuch as extensive industrial structure, low-level industries and high degree of government-owned businesses remain outstanding. As the longstanding obstacle in China's economic growth, we must seek radical policies from the institutional level to ensure the quality of China's industrial and economic development and thus achieve sustainable industrial growth (Li Keqiang, 2018). The academic circle has conducted considerable researches on the above issue from diversified perspectives and with abundant literature (Li Jianbo, 2014, Liu Yang, 2015, Li Yining, 2015, Ren Zeping, 2016, Wei Feng, 2014), whereas little literature analyzes the mechanism from the perspective of systems and development strategies. Therefore, this paper attempts to study industrial transformation and upgrading from the perspective of development strategies.

2 Mechanism Analysis of the Influence of Development Strategies on Industrial Transformation and Upgrading

The government itself is the most significant institution in the economy whose economic policies can usually be summarized as development strategies (Lin Yifu, 2017). It is quite natural and reasonable, considering the historical context, for the Chinese government to implement a top-down extensive growth strategy to catch up with others since the People's Republic of China was founded. Undeniably, such a strategy as based on the expansion of the quantity of inputs, and especially on massive investment, creates a remarkable Chinese miracle (Wu Jinglian, 2013). At the same time, however, problems such as perennial dependence of industrial upgrading on investment, relatively insufficient consumer demand and overcapacity are becoming increasingly prominent. All these have impaired the quality of industries and their sustainable growth capacity.
Figure 1   China's economic growth rate each year (%)
source: website of National Bureau of Statistics

How does the extensive growth strategy cause an unbalanced industrial structure, in other words, what's the mechanism behind it? First of all, from the perspective of unbalanced structure of domestic demand--the most superficial issue--the most direct reason why investment far exceeds consumption is that the investing entity's (government departments and enterprises) income far exceeds the consuming entity's (residents). It's true that government and enterprises control more national income while residents' income has been decreasing in the past few decades. The uneven distribution of national income directly leads to unbalanced structure of China's domestic demand (Xu Xiaonian, 2010). In addition, the production part lies before the distribution part in large-scale socialized production. Therefore an unbalanced distribution of national income is directly led by an unbalanced productive structure. If there are more capital-intensive industries, the distribution of income will be more conducive to capital rather than labor. Last but not least, the extent to which China's industrial structure inclines towards capital-intensive industries far exceeds the abundance of capital. Apparently, government's improper policies featuring forging ahead such as large-scale investment on infrastructure, facilitating financing for capital-intensive companies, lowering capital prices through interest rate regulation will distort the macro incentive mechanism for companies and generate more capital-intensive enterprises.

Table 1   Uneven National Income Distribution

Government real income (% of GDP, in 100 million)

Year	Tax	Land-Transferring Fees	Social Security Fund	State-Owned Enterprises	Lottery Sales	Extra-Budgetary and Non-Tax Revenue	Excluded from the Budget	Real Income of the Government	Total Size of GDP	Proportion of Government's Revenue on GDP
1995	6038		187			2938	680	9843	59810	16.45
2000	12581	522	1006		181	4919	1476	20685	98000	21.10
2005	28778	5505	2645		411	8608	2582	48529	183617	26.43
2010	73211	28198	19276	440	1662	16693	5316	144796	399759	36.22
2011	89738	31140	25153	700	2216	14136	6016	169099	468562	36.09
2012	100614	26652	30739	1154	26158	16639	7290	185703	518214	35.84
2013	110497	39073	35253	1288	3093	18645	8828	216677	566130	38.27

source: Hengda Research Center

In summary, China's economic structural imbalance is not simply a structural imbalance of domestic demand but rather a systematical imbalance. The perennial extensive growth mode is the fundamental factor which has distorted the macro incentive structure for enterprises. It first directly leads to an unbalanced productive structure (deep structural imbalance) and then the imbalance will be transmitted to the distribution of national income (middle level structural imbalance) and ultimately, will cause the unbalanced structure of domestic demand (the most prominent structural imbalance).

China's industrial policies since 1949 has facilitated industries that surpass our comparative advantages, such as capital and technology-intensive industries. Li Yifu (2017) described it as a forging ahead strategy. With profound changes in the political and economical environment at home and abroad, its unsustainability is becoming more and more conspicuous and it will constrain the industrial upgrading and economical transformation in the foreseeable future:

2.1 Deviations in China's industrial structure

On the one hand, China's industrialization grew rapidly amid low levels of per capita GDP, surpassing its own factor endowment and the stage of economic development, resulting in a productive structure that is not adapt to the demand structure determined by average income (Huang Qunhui, 2014). On the other hand, the extensive development strategy has led to a deviation in comparative share among labor-intensive, capital-intensive and technology-intensive industries. Large-scale, long-term loans flow to capital and technology-intensive industries. According to the data provided by the official website of the People's Bank of China, from 2000 to 2007, the proportion of medium and long-term loans grew from 26.7% to 70%.

2.2 Long-term distortion of factor prices

China's capital accumulation has outpaced GDP growth because of capital preference of the forging ahead strategy. This development model use to be the driving force of China's skyrocketing

economic growth while effectuated systematical distortion of factor prices at the same time (Lu Ming, 2014). Intentionally depressed prices of capital, land and energy have prompted government departments to increase subsidies towards enterprises, causing sever consequences such as low productivity, investment-driven growth, environmental pollution and inappropriate industrial structure.

2.3 Overcapacity and waving phenomenon

The emerging industries supported by the government are always advanced ones. The waving phenomenon happens when, affected by the policies, countless companies and investors are highly consistent in the assessment of one industry (Fu Caihui, 2016). Most of government-supported industries don't meet the requirements of comparative advantage and are more likely to suffer from overcapacity and waving phenomenon, such as steel, cement and petrochemical industries.

3 Suggestions for New Policies

Based on the current stage of Chinese industry, systematical improvement of innovation and stimulation of innovative vitality should be concentrated on the following aspects:

3.1 Strengthening the establishment, reform and improvement of the institutional cost of industrial innovation

Institutional cost is the premise of industrial innovation and the institutional cost of China's industrial innovation is still relatively high. First, laws and regulations on rewards, equity, options, taxation, room for trial and error and other aspects must be improved. Secondly, reducing financing cost, especially for small and medium sized private enterprises is significant. The third suggestion is to establish and improve the risk control mechanism for industrial innovation. The government must set up funds and subsidies for risky projects.

3.2 Accelerating talent fostering

To begin with, by fostering respect for science, government departments should create a conducive atmosphere for scientific innovation and consolidate talent sources. In addition, the government need to unlock the scientists' creativity and entrepreneurial passion, fully support enterprises to attract more innovative talents and encourage talents to work for enterprises. What's more, we should master the laws of innovative talents fostering and expand the recruitment pool.

3.3 Removing institutional barriers that hamper population movement and migration of workers

Initially, barriers that hinder talent flow such as household registration, restrictions on gender and age should be eliminated. Additionally, based on the two-child policy and the act of raising the retirement age, the government must deepen reform of population policy, slow down the aging population and mitigate its negative effect on innovation. Furthermore, government service models and grassroots governance also require innovation. More attention should be paid to public service and policies pertinent to migrants. Finally, the government should expand exchanges of talents abroad and proactively guide the inflow of overseas talents.
Figure 2   Population in China in 2015 and 2050, by Age and Gender (In Million Inhabitants)
source: website of National Bureau of Statistics

3.4 More governmental investment in infrastructure such as science, education, culture and health

During the past four decades, the government has paid disproportionate attention to infrastructure and achieved a infrastructure miracle. Meanwhile, we should bolster points of weakness or soft environment, so that the coordinated development of hard and soft environment can better attract, serve and facilitate talents.

3.5 Establishing and improving talent incentive system

First of all, it's pivotal to make flexible use of wages, performance, benefits, employee stock ownership and other compensation mechanisms to mobilize their passion for innovation. Meanwhile, enterprises can attract and keep talents with people-oriented cooperate culture, formulate a blueprint for their future career to maintain a prolonged incentive. Furthermore, enterprises should provide sound working conditions and channels for enhancing personal value.

3.6 Enhancing exchanges and cooperation with other countries and regions, expanding the scale of opening up, strengthening exchanges, absorbing talents and providing an effective way for enrollment

To start with, we need to create a sound living and working environment to attract high-level overseas returnees and foreign. In addition, we can improve the political and commercial environment to facilitate international trade and acquire knowledge from trade. What's more, we spur foreign direct investment so that we can enjoy their knowledge and technological spillover effect. Last but not least, the international licensing system proves to be an effective way for developing countries to obtain certain new proprietary technology and its cost benefit is even more feasible than the enterprises' own development.

To sum up, at the backdrop of complex international situation and economic downturn in China, industrial transformation and upgrading, together with innovation, are what China must do now in avoiding a middle-income trap and pursuing development and prosperity. At present, we need to deepen our understanding of the urgency, necessity and importance of industrial transformation and upgrading and innovation. Further discussion and research on the national development strategy, strategic support and guidance for industrial upgrading and innovation are paramount.

4 Conclusion

The extensive forging ahead development strategy since 1978 has profoundly stimulated industrial progress and industrialization. Meanwhile it has left numerous structural problems, for example, it has directly led to deviations in China's industrial structure, long distorted factor prices and overcapacity and waving phenomenon. Admittedly, the strategy has its historical inevitability and rationality. However, the Chinese economy is undergoing a major transition to a post industrial economy nowadays. The past forty years have witnessed China's unprecedented economic growth-- in fact, China has shifted gear from the previous high speed to a medium-to-high speed growth--for example, affluent capital accumulation, major changes in factor endowment structure , and many companies that used to be lack of viability now can survive the fierce competitiveness and even go global to provide foreign companies with technologies and services. The major economic changes make it imperative for the government to keep abreast of the changing times and seize opportunities to readjust its economic structure, adopt a development structure that is more responsive to comparative advantage, that is, the innovation-driven development strategy.

At present, we need to deepen our understanding of the urgency, necessity and importance of industrial transformation and upgrading and innovation. Further discussion and research on the national development strategy, strategic support and guidance for industrial upgrading and innovation are paramount. The first three aspects of this paper are particularly important in the six aspects of industrial transformation and upgrading. It is necessary to deepen and broaden the research, and to study in an international perspective. At the same time, it is necessary to combine the current complex and ever-changing international situation, carry out comparative research, and propose more targeted and practical measures for China's industrial transformation and upgrading!

Abstract: With the rapid increase of highway mileage and traffic flow, the numbers of highway accidents and casualties have a year-on-year rise. Therefore, the highways' scientific management system must be established and improved while perfecting the construction the highway infrastructure, especially the establishment of the highway emergency rescue system. In this paper, the planning system of actual highway emergency rescue, which combined with Hierarchy Task Net (HTN) planning technology, is established based on the features of highway emergency rescue. The experiment shows that this method can quickly generate the planning of highway emergency rescue tasks in complex environments with a wide range of applications, good scalability, and good practical value.
Key words: Highway; Emergency decision; Artificial intelligence; Hierarchy task net planning

1 Introduction

The continuous development of transport capacity is a necessary guarantee for a country's modernization. Because of highway's outstanding advantages in terms of fast transportation speed and high flexibility, it has become a basic project for the vigorous construction of various countries. In recent years, China has continued to vigorously promote the construction of highways, and the mileage of highways has been increasing year by year. By July 2017, China has built 131,000 kilometers of highways, and the total mileage is the first in the world, providinga guarantee for the rapid development of China's economy. However, with the rapid increase of highway mileage and traffic flow, the number of highway accidents and casualties also increase quickly. For this reason, the highways' scientific management system must be improved while perfecting the construction the highway infrastructure, especially the establishment of the highway emergency rescue system. In this way, the number of highway accidents can be minimized, the survival rate of the wounded in the accident can be increased, and the tragedy can be avoided.

At present, China's highway management departments have also designed and developed some systems for emergency rescue of highways. For example, in 2009, Shandong Highway established a highway's daily management and emergency rescue system, which can assist relevant personnel in the management of road network information, police information, resource information, emergency plans etc., and in the decision-making of the highway emergency rescue. Lv Baohe (Lv Baohe, 2006) analyzed the existing problems in China's highway traffic accident rescue system, and gave the interaction relationship among elements of emergency rescue. Li Zheng (Li Zheng, 2015) analyzed the new requirements of highway emergency rescue decision-making in detail, and developed the actual software based on web-GIS and B/S to achieve the support of various rescue departments in information sharing and decision-making. For the specific details of highway emergency rescue, such as resource scheduling, scholars have also conducted a lot of research.Yarnad T (Yarnad T, 1996) studied the role that the timely and effective schedule ofmaterials and medical resources play in shortening rescue time and reducing accident losses after a traffic accident. Takeo Yamada (Takeo Yamada, 1994) etc. transformed the path selection problem of emergency rescue into the shortest path solving problem.The shortest path solution is divided into static shortest and time-varying shortest, and the study of the shortest time-varying path is of great significance to the schedule of highway emergency materials. J Ali Haghani (Haghani, 1996) etc. used the network flow model to solve the problem of rational scheduling of various emergency supplies in different modes of emergency rescue. Most of the above studies on key technologies and resource scheduling in highway emergency rescue are focused on establishing a fixed mathematical model, and then solving it using operational research and other related mathematical methods to get an emergency rescue plan for highway accidents. However, general accidents, including highway accidents, which have features of sudden and random, is an unstructuredissue, making it difficult for to establish an ideal mathematical model and then calculate through an optimization algorithm to obtain the plan.

Compared with the traditional operational research, modeling and other planning methods,

hierarchical task network (HTN) planning, whichis a popular branch in artificial intelligence, can solve it well. Hierarchical task network planning can simulate humans to understand and analyze the planning environment. Based on the objectives that the plan needs to achieve, it imposes inferences on a number of alternative actions and the provided resource constraints to comprehensively formulatethe plans that can achieve the goals. It can provide a technical basis for the construction of highway emergency rescue task planning system and reduce the workload of rescue workers. It greatly accelerates the speed of task planning, improves the effectiveness of rescue operations, and reduces the loss of personnel and property.

2 Principles of HTN-based Highway Emergency Rescue Planning Method

The HTN planning method (Wang Z, 2013), which is based on the precondition reasoning of the state, realize the top-down task decomposition and action reasoning process according to related domain knowledge. Sacerdoti proposed the basic idea of HTN planning in 1975 (Sacerdoti E D, 1975). The intelligent planning system –Nonlin (Biundo S, 2001), designed by Tate in 1977, is an earlier implementation of the HTN planner. Erol conducted a theoretical study of HTN planning and analyzed the complexity of HTN planning (Erol K, 1995). In 1994, he designed the first HTN planning system UMCP with reliability and completeness. Because of its strong expression and reasoning abilities, HTN planning can make clear and effective expressions of complex decision-making issues and efficiently manage related domain knowledge. With the progress of intelligent planning from the laboratory to the engineering practice, the HTN planning method has gradually become the most widely used intelligent planning method in practical engineering (Wilkins D E, 2001). Therefore, HTN will be used to establish a highway emergency rescue task planning system in this paper.The HTN planner generally goes through the following four steps in the development of the highway emergency plan. The specific process is shown in Figure 1:

Step1: According to the problem domain model of highway emergency rescue mission planning, the related domain knowledge of highway emergency rescue is transformed into a domain knowledge model of highway emergency rescue;

Step 2: According to the problem model of related highway accident and the domain knowledge model of highway emergency rescue, the domain issues is described;

Step 3: According to the domain description, the planning problem is extracted and concluded;

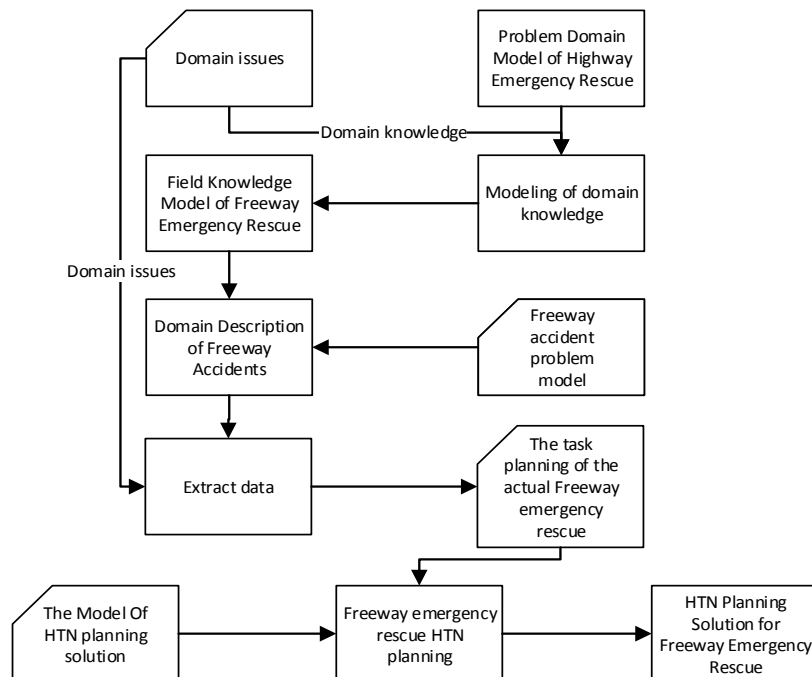
Step 4: The actual highway emergency rescue mission planning problem and the domain knowledge of highway emergency rescue are inputted to the planner. Then the HTN planning algorithm was started to obtain final planning solution.


Figure 1   Highway HTN Planning Emergency Decision Process

The goal of the HTN planner is to recursively decompose the originally abstract top-level target task into a more and more specific sub-task sequence, and to achieve the desired effect of the top-level target task by executing this subtask sequence. The description of the problem domain by the HTN planner consists of a series of operators similar to the classical planner and a series of methods. Each method describes how to decompose from a high-level task into a low-level or atomic task. The process of HTN planning is to use the domain knowledge in related fields to gradually decompose top-level tasks into the simplest atomic tasks, and then get a complete plan for a task.

3 Practical Experiment of Highway Emergency Rescue Planning System

3.1 Case Introduction

In the summer of 2017, due to the slip and poor sight contributed by the heavy rain, two accidents occurred at the same time on a highway, which were located in the A1 and A2 sections. There are two highway maintenance points near the area, located at B1, B2. There are two kinds of resources needed for rescue, stones and ambulances. The resources required and owned by the two accident sites and highway maintenance points are shown in Table 1. The available time for occupied ambulances is shown in Table 2. Now the traffic police department needs to quickly formulate emergency rescue plans for these two accidents. In this case, multiple incident points are corresponded to multiple resource supply points, and the required resources include both consumable resources and reusable resources, which are consistent with the generality of the case. At the same time, this case has a resource shortage problem, which is targeted and can verify the characteristics of the planner developed in this paper. Therefore, this case was taken as an example to verify the effectiveness of the proposed method.

From Table 1, it can be seen that the consumable resource stone will have a gap of 120 tons. From Table 1 and Table 2, it can be seen that there are 8 currently available vehicles, and 4 vehicles will be released in 8 units of time at B1, and 1vehicle will be released in 12 units of time while 3vehicles can be released in 30 units of time at B2, which cannot be requisitioned within the required time. So there will be a gap of one vehicle. We hope to input the planning problem into the planner and obtain a final planning result that includes a resource shortage report in a short time, so that the superior department can find out the resource shortage problem in the rescue process and supply resources in time.

Table 1　Resource Requirements and Resource Status

	A1(demand, time)	A2(demand, time)	B1(reserve, time)	B2(reserve, time)
Stone (tons)	（220,10）	（300,15）	（200,0）	（200,0）
Ambulance	（6,10）	（8,15）	（3,0）	（5,0）

Table 2　Available Time for Ambulances (Reusable Resources)

	B1 (quantity, time)	B2 (quantity, time)
Ambulance	(4,8)	(1,12), (3,30)

3.2 Analysis of planning results

For the above situation, the planning problem P, encoded from the site conditions and rescue goals of the two disaster points according to the Planning Domains Definition Language (PDDL), is inputted into the highway emergency rescue mission planner. The planner will receive the emergency planning problem P and then automatically read the domain knowledge file method. After reading the two files, the planner can gradually decompose the highway emergency planning problem under the guidance of the method, and in turn obtain the emergency rescue plan for this accident.

The rescue plan is divided into two parts: the action plan and the resource shortage report. The action plan consists of a number of specific actions which is similar to (Inform traffic police to enter a1) and is in sequential order. Taking account of the accident site conditions and the resource situations in the highway maintenance points, the planner separately formulated the action plans for the traffic police and firefighting, the plans for traffic control and recovery, and the specific plans of resource scheduling for the two accident points. These plans fit the accident site conditions and can fully adapt to the accident site rescue. Andthe anticipated rescue goals will be achieved in accordance with each step of the action plan. Meanwhile, due to the shortage of resources in this accident, the planner also generated a resource shortage report, which consists of several statements similar to (lack b2 ambulance 1.0 15.0), detailing the types, quantities and times of resource shortage during the rescue process. From this report, we can see intuitively that there was a gap of 120 tons of stone and 1 vehicle at B2 at the 15th moment,

which is consistent with our previous analysis, and can provide a basis for the superior departments to quickly supply the response resources. This test shows that the planner is working properly. It not only generated a highway emergency rescue plan, but also successfully identified resource shortages by giving it in the form of a report. The action plan and the resource shortage report complement each other, and provide comprehensive guidance for the rescue work. At the same time, when testing repeatedly for this problem, the plan was completed within 3 seconds, which is an acceptable range for actual emergency decision-making.

4 Conclusion

The paper analyzed the drawbacks and weaknesses of traditional highway emergency planning methods or auxiliary decision-making systems.In addition, a highway emergency rescue mission planning system based on hierarchical task network planning has been developed. The system can generate a complete highway rescue plan that can guide the rescue process and the supply of resource shortage through the framework generation and specific parameters optimization of the emergency plan. At the same time, it can be seen that the entire planning time is less than 3S, which is an acceptable range for actual emergency decisions. In summary, this system can improve the efficiency and rationality of highway emergency rescue tasks planning and reduce the loss of personnel and property.

Public Opinion Dissemination Model of Emergency in Universities Based on Immunology

Fang Haining[1, 2]
1 School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
2 Department of Student Affair, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: fanghaining@whut.edu.cn)

Abstract: Public opinion dissemination of emergency in universities impacts the normal order in universities, and damages the environment of education. Emergencies in universities have the characteristics of particular subject, social sensitivity and rapid diffusivity, which make the public opinion dissemination more complicated. This paper analyzes the process of public opinion dissemination of emergency in universities (PODEU) based on immunology, develops SIR model of PODEU, and simulates the influence from the number, intervention time, range and influence of real opinion leaders to PODEU. The results showed that cultivating more positive opinion leaders, enhancing the influence of positive opinion leaders, and giving opinion to PODEU as soon as possible will be beneficial to control PODEU.
Key words: Public opinion dissemination of emergency in universities (PODEU); Immunology; SIR model; Real opinion leaders

1 Introduction

In some countries, emergencies in universities are considered to be a specific subset of the field of emergencies in the general sense. Since 1990s, the theories of system security and non-traditional security were appeared, at the same time, crisis management began to enter the field of public management and the campus (Siegel D, 1991). *A Practical Guide for Crisis Response in Our Schools* written by Mark D Lerner and others was considered to be more authority in the campus emergency research, which is known as "a set of comprehensive response plan of campus crisis" (Mark D Lerner, 2003).

Emergency in universities refers tothe emergencies that suddenly erupts and do not follows managers expect, which is because of social environment, natural or man-made factors, and causes damage or threat to society, universities and individual (Li Xincang, 2015). Emergency in universities is a kind of public emergency. Therefore, it has the same characteristics of public emergency, such as sudden, complexity, destructive, variability, etc. In addition, it has its own characteristics on account of its manning and management style.

a. Personnel specificity

The subject in universities can be divided to 2 parts, teachers and students. In universities, especially in emergencies, students are the main subject no doubt. In new period, students have the characteristic of full of vigor so that they are full of knowledge and thought, concerned with social, political and economic development, active and open in thinking, enthusiastic, competitive and curious. However, they also have the characteristics of scarce social experience, immature thought, poor ability to resist setback and distinguish right from wrong, so that they are easily affected by external environment and bring forth aggressive behavior and universities become the social organization of more emergencies.

b. Social sensitivity

Universities are bearing the duty of education, carrying hopes of thousands of families, and the focus of the government, society and media. Once emergency erupts, it will inevitably generate a strong social response and arouse the attention of the whole society. Furthermore, it is very easily impacted by external environment and other related factors, and interact with the outside world to blow up and radiate to become bigger social emergency.

c. Rapid diffusivity

The number of students in universities is generally over ten thousand, even tens of thousands. Almost all the students live in the campus so that it has very big crowd density and homogeneity. Once emergency erupts, negative information can spread easily and rapidly, which urges public opinion to be group action. Especially in the network period, if emergency in universities is not controlled timely, it will be the focus of public opinion because of the information including pictures, words and videos spreading rapidly on all the kinds of new media by students. Highly concentrated physical distance in

universities and spreading rapidly information in new media, form obvious online and offline public opinion coupling network.

With rapid development of network technology, the network has gradually become the main platform for people to exchange ideas, transmit information and spread ideas, and also the main carrier of public opinion of emergencies. In recent years, the research on public opinion of emergencies mainly focuses on communication mechanism (Chen Bo, 2011), monitoring mechanism (Fan Liguo, 2010), early-warning technology (Jianhua Ruan, 2007), etc. From the literature review, the research of PODEU mainly focuses on the perspective of social science and the qualitative description of public opinion evolution mechanism, rarely on the simulation analysis about characteristics of PODEU (Li Zhongchun, 2014) (Huang Youfa, 2011). There is no research on PODEU based on immunology from the existing research results. This paper analyzes the process of PODEU based on immunology, develops SIR model, and simulates the influence from the number, intervention time, range and influence of real opinion leaders to PODEU.

2 The process of PODEU

The agents of PODEU consist of students, online opinion leaders (online media and We-Media) and offline opinion leaders (propaganda department and counselors). The process of PODEU can be abstracted that students release opinions under the joint action of online and offline opinion leaders.

Some scholars have studied emergencies based on immunology (Yang Qing, 2015) (Zhu Hengmin, 2016). In this paper, immunology is applied to the study of PODEU. The states of students can be summarized as three kinds. The first kind does not release opinions, which is identified as susceptible state (S). The second releases negative opinions influenced by negative public opinion, and to be identified as infected state (I). The third releases positive opinions in the influence of positive public opinion, and is considered recovered state (R).

Figure 1 shows the process of PODEU. When emergency in universities begins, t=0, negative online opinion leader A releases rumor, as all the 8 students are susceptible state.

When t=1, student 1, 3, 5 and 6 turn infected state (I) from susceptible state (S), and release rumor in the influence of A, which forms public opinion.

When t=2, positive offline opinion leader B releases opinion by the way of mainstream media and communication with students, which can be considered immunization. Student 5 and 6 turn recovered state (R) from infected state (I); student 3 and 4 turn R from S; student 1, 2, 4 and 7 are immunity failure. Therefore, student 1 and 4 still keep I, student 2 turns I from S, as student 7 is still S.

When t=n, all the students are R or S, and the public opinion comes to the end.

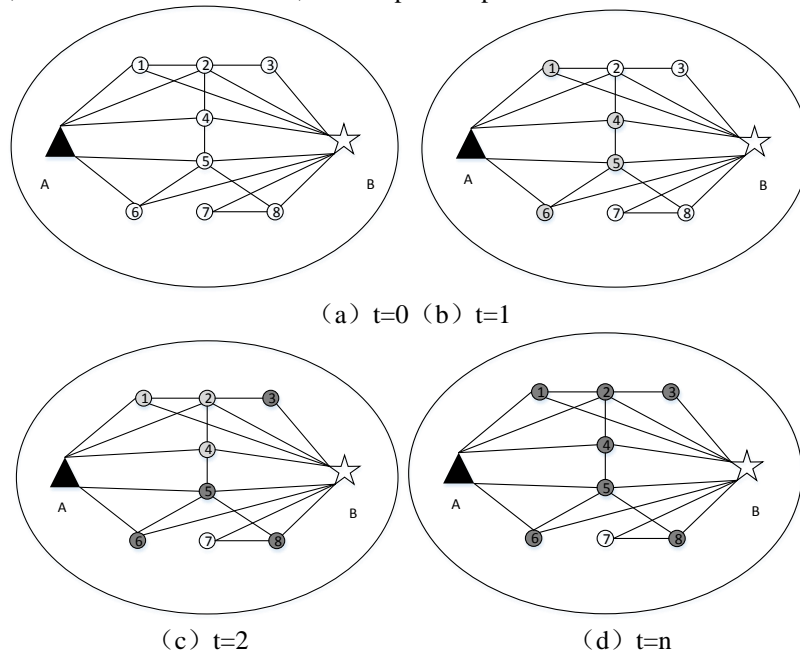

Figure 1   Process of PODEU

3 The SIR Model of PODEU

3.1 Modeling Assumption

The SIR Model of PODEU consists of 3 kinds of agents, which are students, online and offline opinion leaders. This paper proposes assumptions as follows before modeling by Netlogo:

a. All the online opinion leaders release negative information and all the offline opinion leaders release positive information.

b. Every student can be influenced at different levels by online information and offline information, and the level is considered susceptible level (SL). The SL of every student is random in a certain range by system.

c. Initial number, range and influence of all the agents have been known, and the scale of agents has been certain.

d. The attribute of all the agents updates every tick at the same time.

3.2 The attribute of the Agents

The attribute of the 3 kinds of agents is showed as Table 1.

Table 1   Attribute of the Agents

	Agents		
	Students	**Online Opinion Leaders**	**Offline Opinion Leaders**
Attribute	State of Susceptible State of Recovered Susceptible Level (SL) Influence Range Influence Level	Tendency Influence Range Influence Level	Tendency Influence Range Influence Level

3.2.1 Attribute of the Students Agents (SA)

The function of the attribute of the student agent s_i is $F[I_{s_i}(t), R_{s_i}(t), E_{s_i}(t), S_{s_i}(t), A_{s_i}(t)]$, where $I_{s_i}(t)$ shows the state of susceptible of s_i at t, $I_{s_i}(t) \in \begin{cases} [0,0.5) \text{ state of S} \\ [0.5,1] \text{state of I} \end{cases}$. At t=0, the number of the state of susceptible of all the SA is 0.

$R_{s_i}(t)$ shows the state of recovered of s_i at t, $R_{s_i}(t) \in \begin{cases} [0,0.5) \text{ state of S} \\ [0.5,1] \text{ state of R} \end{cases}$. At t=0, the number of the state of susceptible of all the SA is 0. When $R_{s_i}(t) \in [0,0.5)$, SA have low immunity and still stay the state of S or I. When $R_{s_i}(t) \in [0.5,1]$, SA have become the state of R and can't be influenced by negative information. At the same time, $I_{s_i}(t) = 0$.

$E_{s_i}(t)$ shows SL of s_i at t and values in the [0,1] , which does not change in the process of PODEU. A higher value of $E_{s_i}(t)$ indicates the more likely the students are infected or recovered, and the more likely they are influenced by others in the process.

$S_{s_i}(t)$ shows the influence range of s_i to others and $S_{s_i}(t) \in [0,5]$. A higher value of $S_{s_i}(t)$ indicates a higher influence range of s_i to others.

$A_{s_i}(t)$ shows the influence level of s_i to others and $A_{s_i}(t) \in [0,1]$. A higher value of $A_{s_i}(t)$ indicates a higher influence level of s_i to others.

3.2.2 Attribute of the Online Opinion Leader Agents (ONOLA)

The function of the attribute of the online opinion leader agent n_i is $F[T_{n_i}(t), S_{n_i}(t), A_{n_i}(t)]$, where $T_{n_i}(t)$ shows tendency of n_i to emergency in universities. Based on assumption a, $T_{n_i}(t) = 0$.

$S_{n_i}(t)$ shows the influence range of n_i to SA and $S_{n_i}(t) \in [0, +\infty)$. A higher value of $S_{n_i}(t)$ indicates a higher influence range of n_i to SA.

$A_{n_i}(t)$ shows the influence level of n_i to SA and $A_{n_i}(t) \in [0,1]$. A higher value of $A_{n_i}(t)$ indicates a higher influence level of n_i to SA.

3.2.3 Attribute of the Offline Opinion Leader Agents (OFFOLA)

The function of the attribute of the offline opinion leader agent r_i is $F[T_{r_i}(t), S_{r_i}(t), A_{r_i}(t)]$, where $T_{r_i}(t)$ shows tendency of r_i to emergency in universities. Based on assumption a, $T_{r_i}(t) = 1$.

$S_{r_i}(t)$ shows the influence range of r_i to SA and $S_{r_i}(t) \in [0, +\infty)$. A higher value of $S_{n_i}(t)$ indicates a higher influence range of r_i to SA.

$A_{r_i}(t)$ shows the influence level of r_i to SA and $A_{r_i}(t) \in [0,1]$. A higher value of $A_{r_i}(t)$

indicates a higher influence level of r_i to SA.

3.3 The Interaction Principal among Agents

3.3.1 The Influence Principal of ONOLA to SA

At t, ONOLA has a negative impact on SA in the state of S in the influence range. At t+1, the state of susceptible of SA is

$$I_{s_{i+1}}(t) = I_{s_i}(t) + E_{s_i}(t) \times A_{n_i}(t) \times (S_{n_i}(t) - d_{ns}) \tag{1}$$

where d_{ns} is the distance from ONOLA n_i to SA s_i. When the state of SA is I or R, ONOLA have no impact on SA.

3.3.2 The Influence Principal of OFFOLA to SA

At t, OFFOLA has a positive impact on SA in the state of S or I in the influence range. At t+1, the state of recovered of SA is

$$R_{s_{i+1}}(t) = R_{s_i}(t) + E_{s_i}(t) \times A_{r_i}(t) \times (S_{r_i}(t) - d_{rs}) \tag{2}$$

where d_{rs} is the distance from OFFOLA r_i to SA s_i. When the state of SA is R, OFFOLA have no impact on SA.

3.3.3 The Influence Principal of SA to SA

At t, SA in the state of I s_j has a negative impact on SA in the state of S or I in the influence range. At t+1, the state of susceptible of SA is

$$I_{s_{i+1}}(t) = I_{s_i}(t) + E_{s_i}(t) \times A_{n_i}(t) \times (S_{n_i}(t) - d_{ss}) \tag{3}$$

where d_{ss} is the distance from SA s_j to SA s_i.

At t, SA in the state of R s_j has a positive impact on SA in the state of S or I in the influence range. At t+1, the state of susceptible of SA is

$$R_{s_{i+1}}(t) = R_{s_i}(t) + E_{s_i}(t) \times A_{r_i}(t) \times (S_{r_i}(t) - d_{ss}) \tag{4}$$

where d_{ss} is the distance from SA s_j to SA s_i.

4 Results

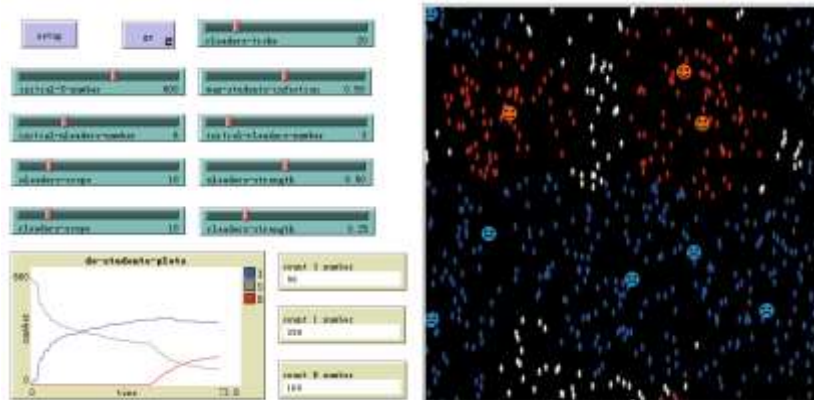
Based on the attribute and the interaction principal above, the SIR model of PODEU is established by Netlogo as shown in Figure 2, and the number of all the agents can be changed. SA are shown by the turtle of the person shape, in which white turtles are representative of SA with the S state, blue are I, and red are R. ONOLA are shown by the turtle of the blue sad face while OFFOLA are the red happy face.


Figure 2   SIR Model of PODEU

4.1 The Impact of the number of OFFOLA to PODEU

The initial condition of a PODEU is assumed as follows: the number of SA with S state is 600, the SL of SA is random in [0,0.5], the influence range is 3, and the influence level is 0.1; the number of ONOLA is 6 with the influence range 10 and the influence level 0.5; the number of OFFOLA is 0, 3, or 6 with the influence range 10 and the influence level 0.5, and intervention time is 20th ticks. The results are shown as Figure 3(a)-(c). A bigger number of OFFOLA indicates a smaller peak of the opinion of emergency in universities, a faster increase of the students with positive opinions, a shorter time for controlling opinion, and better to interdict PODEU.
Figure 3   Impact of the Number of OFFOLA to PODEU

4.2 The Impact of the intervention time of OFFOLA to PODEU

The initial condition of a PODEU is assumed as same as 4.1 except that the number of OFFOLA is 3, and intervention time is 0th, 20th and 40th ticks. The results are shown as Figure 4(a)-(c). An earlier intervention time of OFFOLA indicates a smaller peak of the opinion of emergency in universities, a shorter time for controlling opinion, and better to interdict PODEU.
Figure 4   Impact of the Intervention Time of OFFOLA to PODEU

4.3 The Impact of the influence range of OFFOLA to PODEU

The initial condition of a PODEU is assumed as same as 4.1 except that the number of OFFOLA is 3, and the influence range is 5, 10 and 15. The results are shown as Figure 5(a)-(c). A larger influence range of OFFOLA indicates a smaller peak of the opinion of emergency in universities, a shorter time for controlling opinion, and better to interdict PODEU.
Figure 5   Impact of the Influence Range of OFFOLA to PODEU

4.4 The Impact of the influence level of OFFOLA to PODEU

The initial condition of a PODEU is assumed as same as 4.1 except that the number of OFFOLA is 3, and the influence level is 0.2, 0.5 and 0.8. The results are shown as Figure 6(a)-(c). A larger influence range of OFFOLA indicates a faster increase of the students with positive opinions, a shorter time for controlling opinion, and better to interdict PODEU.
Figure 6   Impact of the Influence Level of OFFOLA to PODEU

5 Conclusion

It is very important to control PODEU for the safety and stabilization. Based on the results, it will be better for controlling PODEU to cultivate more OFFOLA, increase their influence and intervene

earlier.

Abstract: The frequent occurrence of emergencies has made people aware of the importance of emergency management and emergency logistics is on disaster relief. However, in therelative research, few people consider the psychological factors. This article reviews and analyzes relevant literature on human psychological factors in emergency logistics in post-disaster,then proposes that the psychology of both disaster victims and decision makers will affect the implementation of disaster relief andaffect the entire process of emergency logistics. In the emergency evacuation, abnormal psychology caused by individual and environmental factors can affect evacuation results. In the emergency materials distribution, the risk perception caused by rescue supplies and waiting time. In the post-disaster reconstruction, the psychological recovery is related to the perceived waiting time for reconstruction.
Key words: Large-scale emergencies; Psychological factors; Emergency logistics; Risk perception

1 Introduction

In recent years, with the destabilization of international economic development and the damage of environment, natural and man-made emergencies have frequently occurred in all countries of the world and have both shown an upward trend, such as the "9.11" terrorist attacks in the United States in 2001, SARS epidemic in China in 2003, large-scale tsunami in the Indian Ocean in 2004, hurricane Katrina in the United States in 2005, Greece forest fire in 2007, China Wenchuan earthquake in 2008 and snowstorm in South China, Japan's nuclear radiation incident in 2011, Tianjin explosion in 2015 and so on. The occurrence of these large-scale emergencies has caused a great deal of loss of life and property, and has also brought great challenges to national security and social stability. How to deal with these challenges has become a major issue for all countries.

When a disaster event occurs, rescue workers need to respond quickly to make scientific rescue decisions, timely evacuate and safe transferof victims from the disaster site to temporary resettlement sites or medical rescue sites for medical assistance, and choose a reasonable path and program of material deployment relief materials such as food, medicine, and tents were distributed to the victims in a timely manner so as to reduce casualties after the disaster. At present, many scholars in this field have established a very complete theoretical system.In emergency evacuation, HAMZA-LUP G L et al.(HAMZA-LUP G L, 2007)developed an intelligent traffic evacuation management system for the role of modern intelligent transportation systems in the emergency evacuation of emergencies; In emergency supplies distribution, Du Lijing (Du Lijing, 2015) studied the multi-objective and multi-cycle dynamic emergency vehicle distribution vehicle routing problem, a mixed integer programming model for multi-objective and multi-period open vehicle routing problems was established; In the post-disaster reconstruction of reverse logistics, Guo Jingbo (Guo Jingbo, 2013) based on the basic principles of system dynamics, established the ISM model of influencing factors of emergency reverse logistics, and from the aspects of transport resources, inventory resources, and lack of materials due to untimely recovery caused by reusable materials at certain recovery rates. A comprehensive analysis of rescue satisfaction was conducted, and a system dynamics model for reusable material recovery frequency and rescue satisfaction was established.

All the above-mentioned Literatures have made a very meaningful exploration of emergencies and emergency logistics. However, they rarely consider the influence of human psychology, that is, the mentality of decision makers and victims on the effectiveness of emergency logistics. Because emergencies are sudden, unpredictable and destructive, and post-disaster rescue operations have the characteristics of delayed response time and restricted materials, after a disaster occurred, the affected people often bear tremendous psychological pressure and it throughout the entire process like

emergency evacuation, waiting for rescue and post-disaster reconstruction.It is manifested as tension, panic, and this kind of mentality is spread. If it is not properly dealt with, it will lead to extreme behaviors, produce a huge negative public opinion effect and make the impact more than its owns. In addition, decision-makers play a decisive role in the effectiveness of the rescue process in emergency management of disaster incidents. The psychological factors of decision makers will influence the decision-makers' judgment. In previous studies, it was assumed that the decision-makers were completely rational, ignoring the actual rescue. The influence of the decision makers' psychological factors on their decision-making behavior significantly deviates from the optimal solution under calculation, making it difficult to achieve good results when the traditional emergency logistics optimization research results are applied in actual rescue activities.

Therefore, in the process of emergency logistics research, it is necessary and practical to consider the impact of the psychological factors of disaster victims and decision-makers on the effectiveness of emergency logistics. More and more scholars have begun to put disaster victims and decision makers' mentality in the process of emergency logistics. This article summarizes relevant literatures on the human psychological factors in the process of emergency logistics evacuation, material distribution, and post-disaster reconstruction.

2 Psychological Factors in Emergency Evacuation

Emergency evacuation is an effective measure for disaster risk reduction control of sudden crisis events, and it has been a research hotspot for many scholars at home and abroad. However, under the circumstance that the research on emergency evacuation has been relatively thorough and comprehensive, the literature that considers the influence of psychological factors is relatively few and studies only the psychological factors of the evacuees, but does not consider the decision-makers' mentality. When faced with emergencies, due to the stimulation of the external dangerous environment, especially the interference of panic emotions, personnel may easily lose normal mental and behavioral patterns in the evacuation process, leading to the misjudgment of sudden disasters and further irrationality. Harrie C.M. Vorst (VORST H C M, 2010) believes that evacuation models that take into account human behavioral and psychological impacts are more effective. He explores some of the key variables in disaster psychology, and believes that these variables can enhance prediction of human's evacuationbehavior.

In the emergency evacuation process, the psychology of the people to be evacuated is affected by many factors. Zhang Zhihong et al. (Zhang Zhihong, 2013) used statistical methods to analyze the anxiety status of 645 displaced people who had been resettled after the flood and analyzed the relationship between age, gender, smoking, history of hypertension, and SAS scores, then obtained the anxiety level of the post-flood population and its influencing factors. Mu Nana et al. (Mu Nana, 2013) conducted a random survey of subway passengers through questionnaires. It was concluded that factors such as the passenger's gender, baggage status, education level, and safety knowledge had a significant impact on the psychological and behavioral responses of evacuees. Zhou Jian et al. (Zhou Jian, 2014) conducted a questionnaire survey of people's panic in the evacuation of road tunnels, and suggested that evacuation mental behavior was significantly related to gender, education level, fire education level and other factors. Yang Libing (Yang Libing, 2012) investigated and studied the evacuation behavior and psychological characteristics in the case of fire. He conducted 182 employee field surveys on the environment, management, and human factors. Through system cluster analysis, he obtained typical factors and established a test based on the Chi-square test. The evacuation influencing factors contingency table was used to analyze the evacuation behavior and psychological characteristics of fires from different aspects of enterprises, gender, age, and education level. In addition, Xiong Lichun (Xiong Lichun, 2015) used the E-Prime software to simulate the fire environment and recorded the emergency response process of the tested person under conditions of no stimulation, acoustic stimulation, light stimulation, and acousto-optic stimulation. The changes in physiological indicators such as heart rate, electrocardiogram, and blood pressure under various scenarios were analyzed, and the relationship between the physiological activities of the subjects and the subjects was analyzed. The results show that the acousto-optic stimuli have a significant effect on the response rate and response proneness of the personnel under emergency evacuation, causing the staff to generate tension, panic, and aggravating herd behavior that occurs under panic attacks.

By summarizing the relevant literature, it can be concluded that the factors that generally affect the psychology of the victims and their ways of action in the emergency evacuation processare shown in

Table 1.

Table 1   Psychological Factors in Emergency Evacuation

Process	Influencing Psychological Factors		Impact Method	Related Literatures
Emergency Evacuation	Individual	Age	Older people and children are more likely to panic than young people	Ge Xiaoxia (XIAO-XIA G E, 2011), Zhang Zhihong (Zhang Zhihong, 2013), Mu Nana (Mu Nana, 2013), Zhou Jian (Zhou Jian, 2014), Li Xun (Li Xun, 2012),Yang Libing (Yang Libing, 2012), Xiong Lichun (Xiong Lichun, 2015), et al.
		Gender	Women are more likely to panic than men	
		Safety Education	The higher degree of education, the greater the degree of psychological stability	
		Related Experience	No related experience is more likely to panic	
		Carrying Luggage	The heavier the baggage, the easier it is to panic	
		Injury Situation	The more serious the injury is, the more likely it is to panic	
	Surroundings	Personnel Density	Too large and too small can cause panic	
		Evacuation Environment	The more complex the environment, the more easily panic	
		Location of Accident	The farther away from the escape location, the easier it is to panic	
		Export Visibility	The lower the visibility, the easier it is to panic	
		Personnel Guidance	No personnel guidance can cause panic	
		Sound and Light Stimulation	Sound and light stimulation can cause panic	

Although the above literature makes a detailed analysis of the psychological influence factors to be evacuated in the emergency evacuation process, most of the data collection methods are based on questionnaires, the data samples are few. What is more, the scientific and reliable quantitative analysis of various influencing factors is lacking, the mathematical model of the mode of action is not established.

After a disaster occurred, due to conditions such as related resources and safety, the evacuees often need to wait at the accident site, and therefore a waiting price will be incurred in the evacuation process. Cui Xuan (Cui Xuan, 2014) and Zhi-Hua Hu (Zhi-Hua Hu, 2014) established emergency evacuation function model of wounded in disaster area under the influence of psychological cost. The difference is that Cuiused multi-attribute utility theory to establish the basic information measurement function of age, gender, knowledge structure, evacuation experience, measurement function of injury physiological condition, and measurement function of waiting psychological cost affected by time. Encode the model with CPLEX for the casualty evacuation allocation scheme. While Zhi-Hua based on the minimization of psychological punishment costs caused by panic, the cost of psychological intervention and the costs associated with transportation and construction shelters, a new mixed integer linear programming scheme was constructed for multi-step evacuation and temporary placement.Regrettably, Cui did not consider factors such as the disaster level of the source point, the real-time road conditions, and the intersection congestion.

When the waiting time for the evacuees is too long and exceeds a limit, panic will occur. In previous studies, panic psychology was used as a correction factor in the evacuation behavior model. Only the significance analysis was used to determine the influencing factors of panic psychology, and there was no systematic analysis and quantitative analysis of the psychological influencing factors of emergency evacuation panic. The social force model is a commonly used method for studying evacuation behavior. Based on the theory of group dynamics, Helbing (Helbing, 2002) studied the dynamics of people's evacuation behavior in a panic state, pointed out that evacuation under panic conditions, friction between people, and the social force model were different from those in daily life. Therefore, many scholars have improved the social force model under normal conditions and conducted qualitative and quantitative analysis of panic psychology. Wang Chunxue (Wang Chunxue, 2015) conducted a questionnaire survey on the influencing factors of subway evacuation panic. The degree of panic was quantified in combination with the ergonomic social force model anxiety factor correction, and the subway emergency evacuation panic degree model was established. Finally, according to the simulated test data, the relevant accident experience factors in the model are revised to obtain the final

optimization model of subway emergency evacuation panic. Innovation lies in the questionnaire consisted of a panic factor questionnaire and a panic psychological scale. The scores of the scales reflect the panic levels of people under the influence of different panic levels. And correlative analysis was carried out to obtain the weight value of the influencing factors of panic level. But the disadvantage is that the data sample points are less. What is more, Di Yue (Di Yue, 2017) analyzed the factors that affect the psychological stress level of a person in a fire situation, models various types of factors, and established a psychological panic model of people with comprehensive consideration of multiple factors and characteristics of panic attacks. The using of personnel psychological pressure model to improve the social force model and get a new social force model considering the psychological pressure of personnel. The innovation lies in calculating the cumulative panic psychology and establishing an evacuation perception model considering its physiological characteristics and psychological characteristics. The downside is the lack of analysis of real data. In addition, Fang Li (Fang Li, 2014) used the Java simulation language written in the Any Logic simulation software to facilitate research on passenger panic propagation mechanisms and build a multi-agent evacuation simulation model that takes passengers' psychological pressure into consideration. In this model, innovatively predicting the sudden change of emotional changes in the actual emergency by considering the residence time, population density and exit distance.

The panic of the victims will spread to each other, and some scholars have made a quantitative study of the degree of contagion of panic. Wang Jinghong (Wang Jinghong, 2013) studied the spread of panic emotions and their impact on evacuation during large-scale crowd evacuation in terms of evacuation guidance. Using the method of system dynamics, a qualitative simulation model for large-scale crowd evacuation was constructed. By implementing various input schemes for the model, it was discovered whether the panic control or out-of-control condition occurred due to the increased disaster atmosphere during evacuation guidance. The law of change and the spread of panic among people in a disaster atmosphere, are more often result of dominant emotions. It reveals the characteristics of panic sentiment that is very prone to large-scale crowd evacuation and its impact on evacuation.Regrettably, the leaders who are actually likely to exist in the evacuated population and their impact on the normal and panic populations are not taken into account in the model. What is the mutually reinforcing relationship between leaders and evacuation guidance, and how the existence of leaders affects the behavior patterns of the normal population and the panic population. Zhi-hua Hu (Zhi-hua Hu, 2014) innovatively established SIR model was used to analyze the extent of panic spread. Psychological intervention was used to reduce the extent of panic and panic spread. A mixed-integer linear programming model with the goal of minimizing the costs associated with psychological penalty costs, psychological intervention costs, and traffic and building shelters was constructed for multi-step evacuation and temporary placement.

The infectivity of the mind not only affects the mood of the person to be evacuated, but also affects the individual's decision-making. Under the influence and pressure of groups, individuals will no longer insist on their own opinions because of lack of understanding and experience of certain behaviors, which will create a herd mentality. However, this kind of psychological certain evacuation environment will cause more serious casualties. Li Changyu (Li Changyu, 2016) elaborated on the application of Agent theory in urban rail transit stations, influencing factors of emergency evacuation behavior, herd behavior in emergency evacuation, social force model and other emergency evacuation theories, based on the example of subway stations. From the aspects of evacuation personnel attributes, physical model establishment, and simulation experiment design of the simulation model, the herd behavior was simulated in the emergency evacuation of urban rail transit, and the influence of herd behavior on emergency evacuation was analyzed based on the simulation results. The results of simulation experiments show that moderate herd mentality can play a beneficial role in reducing response time and guiding evacuation direction; conversely, excessive blindness can only lead to an increase in evacuation time and a decrease in evacuation efficiency. However, only the influence of herd mentality on evacuation results has been studied. The relationship between panic factors and herd behavior has not been established, and qualitative and quantitative research on the factors influencing herd behavior has been lacking.

3 Psychological Factors in Emergency Logistics Distribution

Material distribution after disasters is an important part of disaster relief. In the dispatch of emergency supplies, the psychological factors of disaster victims and decision makers are both

important factors that need to be considered. If the distribution of emergency supplies takes too long or the distribution is unbalanced, it will cause psychological bias and panic among the disaster victims. The greater negative impact comes from wrong decisions. At the same time, the decision-making behaviors made by decision makers have a significant impact on the operational effectiveness of the entire supply chain system, especially in the decision-makers' different decision preferences. Therefore, based on the research results already obtained in the field of psychology, how to apply the psychological theory of disaster victims and decision makers to the emergency logistics process has gradually become a new hot spot.

3.1 Disaster victims psychological factors

In the formulation of the emergency material dispatching plan, taking into account the psychology of the disaster-hit people and optimizing them to reach the expected value of the disaster victims, it will help the emergency relief work to be carried out in a timely manner and reduce the loss of life and property. In addition to the emergencies themselves, the victims of risk perception are also affected by many factors. Weber (Weber, 2001) reviewed three risk perception paradigms and discussed the impact of human subjective information, cultural factors, and emotional responses on risk perception. In response to the incident, Peng S Q (Peng S Q, 2004) proposed a fear source element, a social element and a self-element. Shi Kan et al. (Shi Kan, 2003) talked SARS as an example to establish a public risk perception structural equation model, and explored and discovered some of the elements that affected panic.Sheu (Sheu, 2014) proposed a conceptual model of the post-disaster survivors' perception-attitude-recovery relationship, conducted normative analysis, established a service distribution optimization modeconsideringspecific classification attitude function for survivors, and established post-disaster relief—a centralized logistics distribution with maximum resilience for survivors.

A large part of the public's perception of risk is due to the scarcity of relief supplies and the panic that cannot be obtained in time for emergency supplies. In large-scale emergencies, supplies are often allocated to less than demand, and the individual needs of disaster victims are difficult to meet. Coupled with regional characteristics, the differences in the amount of material distribution and arrival time, the misunderstandings of victims, and the temptation of rumors, all will result some victims produceunbalanced psychologically and psychological comparisons, even result some irrational behaviors that looted the supplies. Aimed at the first batch of emergency materials distribution problems in multi-supply points in large-scale earthquake disasters,Wang Xuping (Wang Xuping, 2016)established an emergency material distribution modelbased on the irrational comparison mentality of disaster-affected people in disaster-stricken areas. The model was solved using the simulated plant growth method, and the effectiveness of the model and algorithm was demonstrated by examples. Reflecting the reality that the first batch of emergency materials may be unevenly distributed. In addition, due to the spread of panic psychology, in order to avoid some undesirable public opinion effects, Zhang Nana (Zhang Nana, 2016) established the corresponding emergency supplies quantity comparison function and emergency supplies distribution time comparison function in consideration of the irrational comparison of disaster victims. A model for the distribution of emergency supplies in such disasters was constructed. Finally, a heuristic simulation plant growth algorithm for the corresponding model was designed.

In order to make rescue supplies reach the expected mentality of the disaster victims, Chen Leilei (Chen Leilei, 2010) established an emergency material management and dispatching model based on the satisfaction level of the disaster-stricken people in the supply of emergency supplies at the supply point in the event of a large-scale emergency that is less than the demand for emergency supplies at the emergency point. Combining the characteristics of large-scale emergencies, the model is set to be an optimized scheduling model for multi-materials, multiple modes of transport, and multi-vehicles that enable limited resources to be dynamically changed in response to dynamic changes in multiple periods and based on different emergency points. Different weighted value is introduced to the importance of material requirements, so that the allocation of limited resources at the initial stage of emergency rescue can achieve the overall maximum satisfaction.

After the occurrence of emergencies, the public was more sensitive to the timeliness of emergency supplies dispatch. Wang Haixin (Wang Haixin, 2016) subdivided individual factors, event factors, and social factors that constitute a panic psychological perception after the earthquake, without considering other factors and aftershocks. Under the premise of selecting the representative age structure and education background of the affected people, the damage degree of the emergency event and the perceived time of the affected person, the panic psychology was described; on this basis, the disaster

clustering theory was used to divide the affected area. The extent of damage in the region, the parameters of the damage factor, the panic utility coefficient of the individual's characteristics, and the value function of the prospect theory are used to describe the psychological perception time of the affected person, and the effect of perceiving the target based on the panic psychology and the damage coefficient is established. Target, multi-objective emergency material distribution planning model based on the Gini coefficient fair objective. Finally, the variable neighborhood ant colony algorithm program is designed with examples and the model is solved to verify the validity and applicability of the model. However, in this model, it is assumed that each disaster-stricken point only accepts the assistance of a single temporary rescue point. But in actual rescue, it is often the case that multiple temporary rescue points simultaneously rescue multiple disaster-affected points.

In response to emergencies of emergency material distribution and scheduling, the behavioral science and dynamic scheduling methods are introduced into the emergency materials optimization distribution model. Decision makers can formulate corresponding material distribution plans according to the degree of psychological risk perception of disaster victims after emergencies. Many scholars realize that the prospective theory can be used to quantify the psychological risk perception of the victims.Among them, Wang Xuping (Wang Xuping, 2013) and Ma Chao (Ma Chao, 2012) both defined and selected the public psychological expectation time as the time reference point, and obtained the risk perception curve and function model and established a mixed integer programming model aiming at minimizing public psychological risk perception and material unsatisfaction. The final numerical simulation of the corresponding multi-level search algorithm is designed to verify the validity of the model and algorithm. The innovation lies in the use of behavioral operations to integrate it into the distribution of materials. The characteristics of real-time changes in emergencies and the ubiquitous capacity shortage are optimized to optimize the emergency materials dispatching method, which makes it more dynamic and more realistic.

In addition to the distribution and dispatch of emergency supplies, the design of emergency logistics supply networks is crucial. How to consider the psychological factors of the victims in the emergency supply network is also realistic and necessary, but few studies. Sheu (Sheu, 2014) designed the emergency logistics supply network to quantify the psychological costs of disaster victims. Based on the demand, she proposed a design solution to integrate emergency supply networks seamlessly through the integration of three sub-networks of evacuation, medical care, and distribution, and three sub-networks. The connection of the latter network is based on the former arrangement, and a three-phase multi-objective mixed-integer linear programming model is established based on which the total travel distance, the operating cost, and the psychological cost are minimized. It makes up for the lack of research in this area.

The panic of the victims is spread. If they are not dealt with correctly, they will cause negative public opinion effects. For the spread of public opinion may lead to resources snapping, Wang Zhiying (Wang Zhiying, 2016) first defined the scheduling problem through multi-case analysis, that is，the optimal scheduling problem of multi-supply, multi-distribution, multi-demand, and multi-resource flows that features capacity expansion.Then, taking into account the limited rationality of the public, the risk perception behavior was characterized using prospect theory, and the definition of reserve supply rate was given to characterize the preference behavior of decision makers when dealing with public risk perception. Further, by presenting research hypotheses and using prospect theory to represent the public's retrospective supply of resources, taking into account the expansion of the capacity of supply points and distribution centers, a multi-source emergency optimization scheduling system under the context of public opinion transmission is constructed. It provides theoretical support for decision makers to identify the public's risk perception characteristics in the context of public opinion communication and the emergency resource dispatching means to control the occurrence of resource snapping events.

In addition, some scholars consider the impact of the both psychological costs of disaster victims waiting for evacuation at the disaster site and waiting for relief supplies within the resettlement site. Lin Qingfu (Lin Qingfu, 2015) aimed to minimize the economic cost of disaster relief and minimize the psychological penalty costs of the disaster victims. A mixed-integer planning model for the evacuation of quake victims and the distribution of relief supplies was used to determine the short-term disaster supply locations, evacuation of evacuees, and transportation plans for relief supplies, and a specific example was used to validate the proposed model. However, the shortcoming is that only the single disaster site is considered and the impact of the panic spread between the evacuated groups on the disaster relief work is not considered.

3.2 Decision maker psychological factors

In recent years, scholars have generally found that traditional research on the optimization of emergency logistics can hardly achieve good results when applied in real-life rescue activities. The reason is that in actual situations, decision-makers are caused by various objective or subjective influencing factors. The decision-making behavior clearly deviates from the optimal solution under calculation. Therefore, the decision makers' psychological and behavioral factors in the actual decision-making environment are the influencing factors that must be considered in the supply chain research. Yang Jiping (Yang Jiping, 2009) finds that emotion, gender, and task difficulty have a significant impact on decision-making quality factors such as time, confidence, satisfaction, and rate of new programs in crisis decisions. Wang Kai (Wang Kai, 2010) The negative sentiment of decision makers under emergencies leads to a stronger frame effect, and this phenomenon is also affected by factors of gender and problem background, and verified from the perspective of EEG experiments. Lei Ting (Lei Ting, 2016) through analyzing related researches on time pressure, emotion regulation strategies and frame effects in psychology and behavioral decision-making, combined with the inner experience of decision makers in the context of emergencies, put forward relevant hypotheses, and used comparative experiments to examine the time. The influence of stress and emotion regulation strategies on the frame effect of decision makers.

Different decision-makers often face different levels of psychological risks when making replenishment and ordering decisions on relief supplies. For decision-makers in disaster relief centers, the higher the degree of shortage of materials for feedback in the disaster area, the longer the delay in transportation and the perceived risk, the greater its demand for materials and the more urgent it is, and the more proportional it is in a positive proportion. For affected decision makers, the direct source of risk perception is the current inventory of the disaster, the current material demand, and the estimated time of shipment of the next shipment. Wang Xuping (Wang Xuping, 2015) analyzed the impact of two different decision-makers' attitudes of optimism and pessimism on the emergency material allocation process. According to the prospective theory, the rescue center and disaster were respectively constructed for the problem of seismic resource allocation under the dynamic change of road conditions. In order to measure the risk perception of decision-makers for out-of-stock and transit time delays, a system dynamics simulation model for the whole process of material allocation was established from the modules of road capacity assessment, material flow, decision-making process, and material demand. The innovation lies in applying the causality model and feedback structure of material allocation to the decision-maker risk perception model, but the limitation is that only the coordinated operation process of consumable materials in the secondary supply chain is considered.

4 Psychological Factors in Reconstruction

Under the conditions of sudden disasters, little research has been done on post-disaster reconstruction of reverse logistics. Through consulting various types of disaster relief news, it is a fact that in actual rescue work, a large number of construction, living, and medical supplies that were abandoned which were recyclableafter the disaster, and some of the reusable materials accumulated in the disaster area after use. However, the recycling of reusable materials under disasters cannot be ignored. In addition, if the disaster area is not restored and reconstructed in a timely and effective manner, it will result in a negative psychology and aggravate the psychological pressure of the disaster victims, thus causing irretrievable evaluation of public opinion. Therefore, in the actual reconstruction of reverse logistics during the post-disaster reconstruction process, the decision-makers should take into account the psychological factors of the victims, so as to maximize the expected value of the disaster recovery of the victims to better formulate a reconstruction plan.

In this context, there are few studies on reverse logistics management that consider the psychology of the victims. Sheu (Sheu, 2013) studied the reverse logistics system for handling post-disaster debris collection and recovery and found that the psychological recovery of the victims was more stringent than the post-disaster reconstruction requirements. In the formulation of the issue, taking into account the impact of environmental protection, resource recovery, operational risk, and the psychological cost of the affected population, the psychological costs of the affected people include the cost of psychological recovery and the waiting time for perceived reconstruction, and verify that the psychological cost is an incremental marginal integration function. A multi-objective linear programming model that minimizes logistics costs, operational risks, and waiting for psychological costs was established. This research has made great contributions to resource recovery, environmental protection and psychological costs of disaster victims.

5 Conclusion

This article studies and summarizes relevant literatures that currently consider human psychological factors in emergency logistics and finds that in the emergency logistics, psychological subjects mainly involve disaster victims and decision makers, and psychological factors play a role in emergency logistics resource scheduling, emergency evacuation and post-disaster reconstruction. In the emergency evacuation process, the psychological factors affecting the evacuees are mainly individual factors and environmental impacts. After the disaster, the evacuees often need to wait at the accident site and thus have to wait for psychological costs. Waiting for too long can also cause panic. In addition, under the influence and pressure of the community, the evacuees will have a herd mentality, and these psychological factors will affect the final evacuation results. In the distribution of emergency resources, disaster victims and decision makers are affected by many factors in the perception of risk. Except for the emergencies themselves, a large part is due to the scarcity of relief supplies and the fear of being unable to obtain emergency supplies in time.In the reverse logistics ofthe post-disaster reconstruction, the psychological recovery of the disaster-affected people is related to the perceived waiting time for post-disaster reconstruction. The psychological cost of disaster victims is also an important part that decision-makers have to take into consideration during the planning.

On the basis of reviewing and analysing the above literatures, this article puts forward the following opinions:

(1) Most researches are concerned with the psychology of the evacuees and victims, and the influence of decision-makers' psychological research in the in the emergency logistics evacuation, resource optimization distribution and disasters is rarely considered. The specific role of the specific process of reconstruction has much room for research;

(2) Relevant researches are mainly focused on evacuation and material distribution in emergency logistics. In the post-disaster reconstruction, little consideration is given to the influence of human psychological factors and optimization analysis is done. What is more, most of the studies focus on the psychology of the evacuees and victims, while the psychological research on decision makers limits their emotions and risk preferences in the decision-making framework. The specific effects of its specific actions in emergency logistics evacuation, optimized resource distribution, and disaster reconstruction are rarely considered.

In summary, psychological factors are introduced into emergency management to explore the impact of psychological factors on the decision-making and improving the applicability of emergency decisions is of practical significance under the current social background.

Abstract: Emergency logistics is an important task for post-disaster emergencyManagement, which plays a key role in ensuring emergency supplies transported in time and reducing casualties and property losses in the disaster area. After proposing the problem of site selection and path optimization for urban emergency logistics, we establish an urban emergency logistics center location model and use Floyd algorithm to solve it. Then we develop a path optimization model and solve it by shortest expected delivery time network model. At the end, a case is showed to demonstrate Floyd algorithm has a certain of feasibility and practicality to solve this problem.

Key words: Urban emergency logistics; Floyd algorithm; Site selection model; Path optimization model

1 Introduction

In recent years, frequent abrupt disasters did a great harm to our life, which caused a large number of casualties and a huge loss of social property. In this case, how to select favorable emergency logistics distribution centers and arrange fast, effective, accurate distribution route is of great importance to alleviate the spread of disasters and minimize property loss.

In the research of emergency logistics center location and path optimization, scholars preferred to construct a mathematical model and solve it by linear programming or intelligent algorithm. In foreign countries, Boonmee C, eta l (Boonmee C, Arimura M, Asada T,2017) combined an exact algorithm and a heuristic algorithm to settle the problem of Facility location optimization. Fancello G, eta l (Fancello G, Mancini S, Pani C, etal,2017) introduced a Mixed Integer Programming to solve emergency vehicles allocation problem. Behnam Vahdani, eta l (Behnam Vahdani, D. Veysmoradi, F. Noori, eta l,2018) used Two meta-heuristic algorithms of NSGAII and MOPSO to solve Two-stage multi-objective location-routing-inventory model. In china, Hong L, Zhang X (Hong L, Zhang X,2011) developed a multi-objective location selection model based on AHP theory and verified it by MATLAB simulation. Sun Qiang (Sun Qiang,2016) used an improved artificial bee colony algorithm to calculate an emergency logistics center location model with time window. Zhang X, eta l (Zhang X, Zhang Z, Zhang Y, eta l,2013) proposed a bio-inspired method to solve route selection problem. Pan Shiju (Shiju,2016) presented an immunity algorithm to figure out emergency logistics vehicles dispatching problem.

From literature above, we can conclude that most scholars preferred to solve this problem by complicated intelligent algorithm,which is of great difficulty for us to figure it out with no professional computer programming technology. Besides, in many cases, what we get is not the optimal solution with the use of intelligent algorithm. Nevertheless, in this paper, we introduce a simple and practical Floyd algorithm to solve location and path optimization of urban emergency logistics model and a case was demonstrated to prove the feasibility and practicality of this method.

2 Problem Description

As urban emergency logistics is a part of emergency logistics, it exists similar problems that other emergency logistics have. From literature review, the location and path optimization of urban emergency logistics distribution center can be described as: Assuming that a city occurs an abrupt disaster, the quantity of affected nodes are n. The status, distance, material demand, and latest arrival time of each disaster-affected node are known. Now we need to establish m emergency logistics centers in n disaster affected nodes which m is indefinite. Afterwards, on the condition of minimum number of transportation routes, how to arrange transportation vehicles to minimize cost is the work we need to solve. In our urban emergency logistics location model, it meets the following constraints: The ratio of demand nodes to distribution centers is not less than 3, that is $(n-m)/m \geq 3$; Each distribution center serves at least one demand node. The path optimization model meets the following constraints: The time of emergency materials delivering to a demand node must not be later than the latest arrival time of the demand node;

Demand for all affected demand nodes must be met; The sum demand of the nodes on each transportation route must not exceed the vehicle load; The fewer the routes, the better.

3 A Model of Urban Emergency Logistics Location

Emergency logistics has the same structure as general logistics. They are all consist of fluid,carrier,flow direction,circuit,flow,and velocity. In general,we just consider how to arrange transportation routes to minimize costs for general logistics.Nevertheless,the biggest characteristic of emergency logistics that differs from general logistics is that we should firstly take time effectiveness into consideration.As the faster you distribute,more lives and property losses you save.When disaster comes,emergency logistics requiresus to choose the path that minimize transportation time instead of minimizing transportation distance.So it is of a great significance to establish a model of emergency logistics location that save as much delivery time as possible.It is universally acknowledged that there is always traffic jam in city.From the literature that we refer to,we can simply divide traffic condition into six levels. theyare normal traffic,slightly clogged,more clogged,blocking,severe congestion,unable to pass.Corresponding driving speed is v , $0.8v$, $0.6v$, $0.4v$, $0.2v$,0, in which v indicates the average speed of a vehicle drive in a path without traffic jam.In this case,if the distance and the probability of every level of a path are given,then we are able to calculate the expected time of a vehicle driving in this path.The specific calculation method is shown in Table 1.

Table 1   Expected Time of Vehicle Driving from i to j

Situation of i to j	Normal traffic	Slightly clogged	More clogged	Blocking	Severe congestion	Unable to pass
Probability	p_1	p_2	p_3	p_4	p_5	$1 - \sum_{i=1}^{5} p_i$
Average speed	v	$0.8v$	$0.6v$	$0.4v$	$0.2v$	0
E(t)	$L_{ij} / (v p_1 + o.8v\ p_2 + 0.6v\ p_3 + 0.4v\ p_4 + 0.2v\ p_5)$					

According to the method in Table1,we can get a shortest expected delivery time path from i to j .Then the urban emergency logistics location model construction steps are as follows:

(1)Obtain information on road traffic connections of the affected nodes and use the Floyd algorithm to calculate the shortest delivery time matrix where any two nodes are directly connected in one step,which can be represented by the following matrix T_1 :

$$T_1 = \begin{bmatrix} t_{11}^{(1)} & t_{12}^{(1)} & \cdots & t_{1n}^{(1)} \\ t_{21}^{(1)} & t_{22}^{(1)} & \cdots & t_{2n}^{(1)} \\ \cdots & \cdots & \cdots & \cdots \\ t_{n1}^{(1)} & t_{n2}^{(1)} & \cdots & t_{nn}^{(1)} \end{bmatrix} \tag{1}$$

Among them, $T_{ij}^{(1)} = \begin{cases} 0 & i = j \\ \infty & i 、 j \text{ not connected} \\ t_{ij} & \text{the shortest expected transport ation time from i to j} \end{cases}$

(2)iterate T_1 to T_k . When $T_k = T_{k-1}$, iteration stops.At this point,we get the shortest expected delivery time matrix of any two nodes in affected area.

(3) Based on the results above,we develop an urban emergency logistics distribution center location model as follows:

$$\min z = \sum_{i=1}^{n} t_{j1,i} \tag{2}$$

$$\text{sumproduct}(--\{t_{j2,1}, t_{j2,2}, \cdots, t_{j2,n}\} > \{t_{j1,1}, t_{j1,2}, \cdots, t_{j1,n}\}) \geq 2 \tag{3}$$

$$\text{sumproduct}(--\{t_{jm,1}, t_{jm,2}, \cdots, t_{jm,n}\} > \{\min(t_{j1,1}, t_{j2,1}, \cdots, t_{jm-1,1}), \min(t_{j1,2}, t_{j2,2}, \cdots, t_{jm-1,2}),$$
$$\cdots \min(t_{j1,n}, t_{j2,n}, \cdots, t_{jm-1,n}) \geq 2 \tag{4}$$

$$u_{im} = \left\{ jm \left| \min((\sum_{i=1}^{n} \min(t_{j1,i}, t_{j2,i}, ..., t_{jm,i}), (\sum_{i=1}^{n} \min(t_{j1,i}, t_{j2,i}, ..., t_{jm-1,i}, t_{jm+1,i})) \right) \right\} \tag{5}$$

$$(n-m)/m \geq 3 \tag{6}$$

Objective function (2) represents that we need to find a node j_1 as the first distribution center whose sum shortest expected delivery time to all other nodes is minimal;constraints (3), (4), (5), (6) indicate that we can search other nodes as distribution centers that can shorten the sum shortest expected delivery time from centers to demand nodes by the use of base center node j_1 . Among them, (3) and (4) meet the requirements for each emergency logistics distribution center to serve at least one demand node. (5) means that the selected distribution center node is optimal among all alternative nodes.(6) Limits the number of emergency logistics distribution centers established in the affected area.

4 A model of Urban Emergency Logistics Path Optimization
4.1 Model establishment

We suppose that $G(V,E,L)$ is connected network graph with no direction.Point set $V = \{v_i | i = 1,2,...,n\}$ .Among them, m nodes are distribution center nodes. It is the starting point and destination of the entire emergency logistics distribution,which means that all participating vehicles must return to original distribution center after completing delivery task.The other n-m nodes are demand nodes whose demand is fulfilled by m distribution centers.Each demand node can only be fulfilled by one of these distribution centers.Point set $E = \{e_{ij} | i = 1,2,...,n; j = 1,2,...,n\}$, e_{ij} denotes the route from node i to j.Point set $L = \{l_{ij} | i = 1,2,...,n; j = 1,2,...,n\}$, l_{ij} denotes the distance from node i to j.There are k types of vehicles involved in transportation,each type of vehicle load and weight denotes s_k and w_k respectively.The demand of node i is $d_i (d_i > 0)$ and its latest arriving time can be represented as LT_i . t_{ij} is the time of vehicle driving from i to j.Ignore cargo unloading time and define the following four 0-1 variables:

$$x_{ijk}^r = \begin{cases} 1 & \text{type k vehicle r drives from i to j} \\ 0 & \text{otherwise} \end{cases}$$

$$x_{ojk}^r = \begin{cases} 1 & \text{type k vehicle r delivers materials from center o to node j} \\ 0 & \text{otherwise} \end{cases}$$

$$y_{ik}^r = \begin{cases} 1 & \text{type k vehicle r delivers materials for i} \\ 0 & \text{otherwise} \end{cases}$$

$$p_k^r = \begin{cases} 1 & \text{type k vehicle r involves in transport} \\ 0 & \text{otherwise} \end{cases}$$

Based on the conditions above, an urban emergency logistics path optimization model with the lowest total transportation cost is established as follows:

$$\min C = \lambda \sum_{r=1}^{R} \sum_{k=1}^{K} \sum_{j=1}^{n} \sum_{i=1}^{n} x_{ijk}^r l_{ij} w_k + \lambda \sum_{r=1}^{R} \sum_{k=1}^{K} \sum_{j=1}^{n} d_j \sum_{o=1}^{m} x_{ojk}^r l_{oj} \tag{7}$$

$$\sum_{r=1}^{R} \sum_{k=1}^{K} y_{ik}^r = 1 \tag{8}$$

$$\sum_{i=1}^{n} x_{ijk}^r = y_{jk}^r \quad j \in [1,n]; k \in [1,K]; r \in [1,R] \tag{9}$$

$$\sum_{j=1}^{n} x_{ijk}^r = y_{ik}^r \quad i \in [1,n]; k \in [1,K]; r \in [1,R] \tag{10}$$

$$\sum_{r=1}^{R} \sum_{k=1}^{K} \sum_{i=1}^{n} x_{iok}^r = \sum_{r=1}^{R} \sum_{k=1}^{K} \sum_{j=1}^{n} x_{ojk}^r \tag{11}$$

$$\sum_{i=1}^{n} d_i y_{ik}^{r} \leq s_k \tag{12}$$

$$t_i \leq LT_i \tag{13}$$

$$\min \sum p_k^{r} \tag{14}$$

In this model,objective function (7) indicates that the total transportation cost is the lowest when the constraints are met.The first part of the function refers to the cost of the vehicle's own weight during transportation and the latter part refers to the cost of materials weight during the transportation. λ indicates the cost of per kilometer of transport per ton of material(yuan/(km * t)). o denotes the emergency logistics center. $x_{ojk}^{r} l_{oj}$ refers to the distance of type k vehicle r driving from emergency logistics center to node j .Forexample,if vehicle r driving route is o-i-s-j,then $x_{ojk}^{r} l_{oj} = l_{0i} + l_{is} + l_{sj}$;Constraint (8) indicates that each node can be transported material only once;Constraints (9) and (10) mean that the arranged transportation vehicle can only deliver the materials to the node of specified route;Constraint (11) represents that the vehicle from the distribution center must finally return to the original distribution center;Constraint (12) indicates that the sum demand of the nodes on every delivery route must not exceed the vehicle load;Constraint (13) represents that the vehicle reaches the node no later than the node's latest arrival time;Constraint (14) means that the fewer the number of routes to arrange for transportation, the better.

4.2 Model implementation

In order to calculate the optimal path for the urban emergency logistics distribution,we design series of algorithm steps to realize it which are under the constraints.They are as follows:

Step 1: As we get urban emergency logistics distribution centers by Floyd algorithm,then we can calculate the demand nodes that they are responsible for respectively.We use O to denote the set of m distribution centers.Among them, the set of demand nodes responsible for distribution bycenter o is, which means thatthe demand node is delivered by the center whose delivery time is shortest. $U_{oj} = \{j | t_{oj} = \min \{t_{1j}, t_{2j},...., t_{mj}\}, j = 1,2,..., n\}$.

Step 2: Draw the network model of node-connected shortestdelivery time by the shortest delivery time matrix T_k. Then select one of thedistribution centers to find out a node j which is the most urgentdemand node that the distribution center is responsible for by calculating $u_{oj} = \{j | \min(t_{oj} - LT_j\}$.

Step 3: Confirm weather there are other demand nodes on this transport path.If there are other demand nodes that meet constraints,search a route in which the transportation cost is minimal.If don't,split the node that do not meet the constraints and add a new path.

Step 4: Keep on delivering the most urgent delivery time nodes from the remaining undelivered nodes of the distribution center until all them are delivered. Then the optimal path of this distribution center is obtain.

Step 5: Continue step 2 and step 3 to find out the optimal path of the other distribution centers and finally obtain the optimal path that contains all the demand nodes.

5 Case Validation

In order to verify whether the urban emergency logistics distribution center location model and path optimization model above are valid, in this article, we introduce a specific case to verify it.Assume that it happens to be a disaster in a city in which disaster affected nodes are ten.We number it ①-⑩.Suppose that there is only one kind of light transport truck in the affected area, weighing 3 tons,that is $w_k = 3t, k = 1$,load 6 tons, that is $s_k = 6t$, The average driving speed of this kind of vehicle is 40km/h.The demand for materials and the latest arrival time for each disaster-affected node are shown in Table2.

Table 2　Demand and Latest Arrival Time of Nodes

Nodes	①	②	③	④	⑤	⑥	⑦	⑧	⑨	⑩
$d_i(t)$	1.6	2.4	1.5	1.9	2.1	1.7	2.3	2.7	1.5	2.3
LT_i (min)	120	90	45	90	150	120	75	90	60	120

Firstly, the shortest expected delivery time matrix of any two nodes connected in one step is obtained by Floyd algorithm which is denoted as T_1, shown in Table 3.Then iterate it to T_4, which is the shortest expected delivery time matrix ofany two nodes, shown in Table 4.

Table 3   The Shortest Expected Delivery Time Matrix of Nodes(T_1)   unit: minutes

	①	②	③	④	⑤	⑥	⑦	⑧	⑨	⑩
①	0	37	44	∞	∞	∞	∞	25	41	53
②	37	0	29	25	42	∞	22	∞	32	35
③	44	29	0	27	∞	∞	∞	∞	∞	∞
④	∞	25	27	0	37	∞	∞	∞	∞	∞
⑤	∞	42	∞	37	0	19	∞	∞	∞	∞

⑧	25	∞	∞	∞	∞	∞	17	0	36	47
⑨	41	32	∞	∞	∞	∞	36	36	0	30
⑩	53	35	∞	∞	∞	∞	∞	47	30	0

Table 4   The Shortest Expected Delivery Time Matrix of Nodes(T_4)   unit: minutes

	①	②	③	④	⑤	⑥	⑦	⑧	⑨	⑩
①	0	37	44	62	79	63	42	25	41	53
②	37	0	29	25	42	43	22	39	32	35
③	44	29	0	27	64	72	51	68	61	64
④	62	25	27	0	37	56	47	64	57	60
⑤	79	42	64	37	0	19	40	57	74	77
⑥	63	43	72	56	19	0	21	38	57	78
⑦	42	22	51	47	40	21	0	17	36	57
⑧	25	39	68	64	57	38	17	0	36	47
⑨	41	32	61	57	74	57	36	36	0	30
⑩	53	35	64	60	77	78	57	47	30	0
Sum	446	304	480	435	489	447	333	391	424	501

According to Table 4,nodes②and⑦are the distribution centers we are looking for. Center node②transports materials to demand nodes①,③,④,⑨,⑩.center node⑦transports materials to demand nodes⑤,⑥,⑧. Nodes distance matrix corresponding to the shortest expected delivery time is shown in Table 5.

Table 5   Distance Matrix of Nodes   unit: km

	①	②	③	④	⑤	⑥	⑦	⑧	⑨	⑩
①	0	11	13.2	18.9	23.3	22.3	19.4	16.8	12.5	11.5
②	11	0	6.5	7.9	12.3	9.4	6.5	9.1	4.3	6.8
③	13.2	6.5	0	6.6	13.5	15.9	13	15.6	10.8	13.3
④	18.9	7.9	6.6	0	6.9	9.8	14.4	17	12.2	14.7
⑤	23.3	12.3	13.5	6.9	0	2.9	5.8	8.4	16.6	19.1
⑥	22.3	9.4	15.9	9.8	2.9	0	2.9	5.5	8	16.2
⑦	19.4	6.5	13	14.4	5.8	2.9	0	2.6	5.1	13.3
⑧	16.8	9.1	15.6	17	8.4	5.5	2.6	0	6.9	8.6
⑨	12.5	4.3	10.8	12.2	16.6	8	5.1	6.9	0	3
⑩	11.5	6.8	13.3	14.7	19.1	16.2	13.3	8.6	3	0
Sum	148.9	73.8	108.4	108.4	108.8	92.9	83	90.5	79.4	106.5

Finally, with the use of algorithm steps in 4.2,we get the optimal distribution paths of each distribution center.Among them:

Center②distribution paths:②-⑨-⑩-①-②;②-③-④-②;

Center⑦distribution paths:⑦-⑥-⑤-⑥-⑦; ⑦-⑧-⑦.

6 Conclusion

Sustained, high-frequency outbreaks of abrupt disasters increasingly threaten people's lives and property, which have a seriouseffect on people's daily production and lives. Selecting suitable emergency logistics distribution centers and fast, accurate emergency logistics distribution route is an effective way to solve this problem, which is of great significance toalleviate the spread of the disaster and reducethe degree of damage. In this article, firstly, we establish an urban emergency logistics center location model and use Floyd algorithm to solve it. Then we develop a path optimization model and solve it by shortest expected delivery time network model. At the end, with the use of a case in case library, we demonstrate that Floyd algorithm is feasible and practical to solve this problem.

It is obvious that the research direction of this paper is limited to urban emergency logistics,so we take traffic jam into consideration. Nevertheless, there are still some factors that we ignore which have a great influence on the probability of road access, examples like weather, slope, etc. Besides, some other conditions such as rural emergency logistics, urban and rural integration emergency logistics are not considered. We will explore these situations deeply to optimal this model in future study.

Abstract: In order to enhance the effectiveness of earthquake emergency comprehensive exercise, firstly, this thesis proposes an evaluation index system of earthquake emergency comprehensive exercise based on expert professional evaluation, and then standardizes systematization construction of earthquake emergency comprehensive exercise by evaluation and promotion. AHP is used to determine the index weights and the fuzzy comprehensive evaluation method is used to quantitatively process the multi-factor information in the evaluation of the effects of comprehensive earthquake emergency exercises. Finally, the feasibility and practicability of the method are verified by the experiment.
Key words: Earthquake emergency comprehensive exercise; Index system; Analytic hierarchy process; Fuzzy comprehensive evaluation method

1 Introduction

Since the 20th century, nearly 800 earthquakes of more than magnitude 6 have occurred in China. In other word, 23 provincial capitals, 2/3 large cities of China, and more than one million people are located in regions where the intensity is higher than VII degrees. In the event of a major earthquake occurs, casualties and property losses cannot be measured. All departments could carry on the targeted earthquake emergency comprehensive exercise on the day. Although the influence and extensiveness of the earthquake emergency comprehensive exercise is increasing, but in actual operation, there is still a disadvantage that make act is more important than exercise, form is more important than content and demonstration is more important than effectiveness.

Quality and effectiveness of earthquake emergency comprehensive exercise should play a leading role in evaluating the effect of exercise. In 1992, the Ohio Emergency Plan Development Organization developed the first manual for emergency response and assessment of dangerous goods accidents. Homeland security exercise and evaluation program is designed by National Emergency Preparedness Office of US Department of Homeland Security, which became a national exercise evaluation method and operation guide. Kristine M, Gebbie, etc. proposed the use of Delphi method to establish the performance evaluation index system of public health institutions emergency exercise.Fagel believed that exercise evaluation teams should be involved in the exercise design phase. Deng Yunfeng compiled 18 indicators and evaluation criteria covering all major accident emergency exercises in the city. Cheng Qi, et al. set five evaluation indexes for the hazardous characteristics of chemical accidents: economy, environmental protection, safety, coordination and swiftness[0].Yi Tao and Zhu Qunxiong constructed index system based on the characteristics of emergency rescue in terms of disaster relief assessment and exercising results.

However, the evaluation of emergency exercises mainly focused on the specific types of disaster emergency exercises. The main body of research for emergency exercise evaluation is the expert, and the evaluation dimension and evaluation method are relatively single. Therefore, while constructing the scientific evaluation index system for comprehensive earthquake emergency exercises, it is necessary to further analyze the main effects of earthquake emergency comprehensive exercises. It is believed that participants are also an important part of evaluating the effects of emergency exercise. The purpose of this paper is to provide a standardized and operable basis for the evaluation of the effect of comprehensive earthquake emergency exercises by our government and relevant authorities.

2 Research and Design

2.1 Exercise types and processes

Emergency exercise can be divided into desktop exercise, functional exercise and comprehensive exercise.Desktop exercise is a process that simulates disaster scenarios indoors through sandboxes, computers, electronic maps and 3D techniques. The main leaders of each emergency organization will

be discussed, analyzed and extrapolated. Functional exercise refers to the exercise activities that examine a single or multiple emergency response functions in the emergency plan. Comprehensive exercise is an exercise that tests all or most of the emergency response functions in emergency plan.

The comprehensive earthquake emergency exercise process can be divided into three stages.

(1)Exercise preparation phase: The exercise preparation is the foundation of successful practice.

(2)Exercise implementation phase: Exercise implementation is the main part of the whole exercise.

(3)Exercise summary stage: The exercise summary stage includes on-site commentary and post-event summary tracking.

2.2 Evaluation methodology design

(1)Analyze the basic flow of comprehensive earthquake emergency exercises and construct an evaluation index system for earthquake emergency comprehensive exercises.

(2) To compare pairs of indicators, the relative importance of a certain indicator in the coordinate system and its higher-level indicator is represented by the matrix $U = \begin{bmatrix} U_{11} & U_{12} & \wedge & U_{1j} \\ U_{21} & U_{22} & \wedge & U_{2j} \\ M & M & O & M \\ U_{i1} & U_{i2} & \wedge & U_{ij} \end{bmatrix}$. U_{ij} represents the importance of U_i relative to U_j. where, $U_{ij} > 0, U_{ij} = \dfrac{1}{U_{ij}} (i \neq j), U_{ii} = 1$. Use the 9-point method to determine the specific value of U_{ij}.

(3) Calculate the weight of indicators in a single hierarchy. Calculate the product of each row: $A_j = \prod_{j=1}^{n} U_{ij}$, element($i=1,2,\Lambda,n$). Count: $B_i = \sqrt[n]{A_i}$, where n is the order of judgment matrix. Normalize the resulting vector: $W = (w_1, w_2, L, w_n)^T$,that is the eigenvector. Calculate the maximum eigenvalue: $W = \dfrac{B_i}{\prod_{j=1}^{n} B_i}$. Check the consistency of the consistency. if $CR < 0.1$,where $CR = CI / RI$. If there is any error, it is necessary to adjust the element value of the judgment matrix and recalculate it.

(4) Determine the factor set and evaluation set, calculate the membership degree of each index relative to the evaluation set, and establish the fuzzy relation matrix at all levels.

$$R = (r_{ij})_{m \times n} = \begin{bmatrix} r_{11} & r_{12} & \wedge & r_{1m} \\ r_{21} & r_{22} & \wedge & r_{2m} \\ M & M & O & M \\ r_{n1} & r_{n2} & \wedge & r_{mn} \end{bmatrix}$$

(5) Conduct fuzzy assessments based on the known index weight.

$$B = \omega \times R = (\omega_1 \quad \omega_2 \quad \wedge \quad \omega_m) \times \begin{bmatrix} r_{11} & r_{12} & \wedge & r_{1m} \\ r_{21} & r_{22} & \wedge & r_{2m} \\ M & M & O & M \\ r_{n1} & r_{n2} & \wedge & r_{mn} \end{bmatrix} = (b_1 \quad b_2 \quad \wedge \quad b_n)$$

3 Empirical Analyses

3.1 Evaluation object analysis

Taking the "2017 Earthquake Emergency Desktop Exercise in Hubei Province" as the evaluation object, the performance of this method in the actual emergency comprehensive exercise was verified. The exercise scenario envisaged a 5.8-magnitude earthquake in Zigui County, Yichang City, Hubei Province, at 09:05 on the morning of November 22, 2017, resulting in major economic losses and casualties. The exercise is divided into three phases, preparation stage of exercise,the implementation stage of the exercise,and the summary stage of the exercise.

3.2 Analysis of evaluation results

During the exercise, university experts and government emergency center staff are invited to form a group of experts to evaluate the effectiveness of the exercise. The specific process is as follows:

(1) Exercise Evaluation Organization

9 members of the expert group through questionnaire survey and interview were selected to evaluate the importance of the indexes in the evaluation index system of the comprehensive earthquake emergency exercise to calculate the weight of indexes. 20 experts participating in the emergency exercise conducted a professional evaluation on the performance of the exercise indicators. The expert team conducted a comprehensive analysis of emergency exercises.

(2) Professional evaluation

The judgment matrix constructed by expert evaluation and the determined weight of each index are shown in Table 1.

Table 1   Level 1 Evaluation Index Weight of Professional Evaluation

U	U_1	U_2	U_3	W_U
U_1	1	0.36	2.26	0.246
U_2	2.78	1	5.15	0.639
U_3	0.44	0.19	1	0.115

It is concluded that weight: $w_{ij} = (0.246 \quad 0.639 \quad 0.115)$. CR is less than 0.1 (CR=0.004),which means that the matrix is consistent and the weight calculation is effective. Similarly, the weights of the secondary indicators are calculated as follows: $w_1^u = (0.109 \quad 0.499 \quad 0.126 \quad 0.266)$, $w_2^u = (0.223 \quad 0.261 \quad 0.377 \quad 0.139)$, $w_3^u = (0.218 \quad 0.134 \quad 0.648)$. All pass the consistency test.

A total of 20 members of the expert group made professional evaluations on the performance of each exercise. The results are shown in table 2.

Table 2   Level 2 Statistical Indicators Evaluation Results of Professional Evaluation

Secondary indicators	outstanding	good	secondary	bad	Very bad
Exercise plan	3	6	8	3	0
Exercise scheme	2	10	4	3	1
Exercise mobilization training	8	8	3	1	0
Exercise guarantee	7	10	2	1	0
Earthquake emergency start	6	7	5	2	0
Earthquake command deployment	10	8	2	0	0
Earthquake emergency disposal	3	5	5	6	1
Exercise execution guarantee	7	9	2	1	1
Exercise comment	2	2	10	5	1
Site cleaning	8	8	3	1	0
Exercise tracking	1	1	7	8	3

The degree of membership of each index with respect to the comment set is calculated and the fuzzy evaluation matrix can be obtained according to table 2.

$$R_1 = \begin{bmatrix} 0.15 & 0.3 & 0.4 & 0.15 & 0 \\ 0.1 & 0.5 & 0.2 & 0.15 & 0.05 \\ 0.4 & 0.4 & 0.15 & 0.05 & 0 \\ 0.35 & 0.5 & 0.1 & 0.05 & 0 \end{bmatrix}, R_2 = \begin{bmatrix} 0.3 & 0.35 & 0.25 & 0.1 & 0 \\ 0.5 & 0.4 & 0.1 & 0 & 0 \\ 0.15 & 0.25 & 0.25 & 0.3 & 0.05 \\ 0.35 & 0.45 & 0.1 & 0.05 & 0.05 \end{bmatrix},$$

$$R_3 = \begin{bmatrix} 0.1 & 0.1 & 0.5 & 0.25 & 0.05 \\ 0.4 & 0.4 & 0.15 & 0.05 & 0 \\ 0.05 & 0.05 & 0.35 & 0.4 & 0.15 \end{bmatrix}$$

According to the algorithm, the first-order fuzzy evaluation is calculated.

$$B_1 = w_1 \times R_1 = (0.210 \quad 0.466 \quad 0.189 \quad 0.111 \quad 0.025)$$

$$B_2 = w_2 \times R_2 = (0.302 \quad 0.339 \quad 0.190 \quad 0.142 \quad 0.026)$$

$$B_3 = w_3 \times R_3 = (0.108 \quad 0.108 \quad 0.356 \quad 0.320 \quad 0.108)$$

The final results of the comprehensive fuzzy evaluation are as follows:

$$B_U = w_U \times R_U = (0.257 \quad 0.344 \quad 0.209 \quad 0.155 \quad 0.035)$$

4 Conclusion

It is of great significance to carry out pre-disaster comprehensive exercise due to the the destructive power of the earthquake. In order to improve the effectiveness of the comprehensive earthquake exercise, this paper firstly determines the evaluation index system of the earthquake emergency comprehensive exercise by expert evaluation method and literature data. Secondly, the AHP and fuzzy comprehensive evaluation method are combined to evaluate effect of comprehensive earthquake emergency exercise. Finally, 2017 Earthquake Emergency Desktop Exercise in Hubei Province is taken as an example to verify this method. the main conclusions of this paper can be concluded as follows:

(1) Combining AHP and the fuzzy comprehensive evaluation method is to improve the accuracy of this evaluation model.

(2) The corresponding indicator system should be adjusted in response to specific earthquake emergency exercises accordingly.

Abstract: Due to the deteriorating global environment, natural disasters occur more frequently in various parts of the world. China has a vast terrain andnatural disasters such as floods, typhoons, mudslides, droughts, and earthquakes occur from time to time, seriously threatening people's lives and property. Therefore, on the basis of analyzing the existing rescue model, it is great significance to have a more comprehensive and adaptable new rescue model to reduce the loss of people's lives and property. This paper first analyzes the literature related to rescue and evacuation routes, and proposes that multi-target rescue models should be established in the routing planning, taking into account factors such as time window, demand diversity, reliability and satisfaction. The second part summarizes the vehicle routing planning research in a random environment, but mainly for the mass transit network. There are few studies on disaster relief, so more randomness should be considered in the routing planning process of emergency materials. The rescue model under some fuzzy conditions is also analyzed later. The last part is to analyze the application of time-space network model in emergency rescue path planning. This is also the new path planning model proposed in this paper based on the analysis of other scholars' research. It is also the main innovation point of this paper. By analyzing the application of time-space network model in other traffic fields, the feasibility of using **time-space** network model for path planning of emergency materials distribution vehicles is proposed. Then, this paper demonstrates this model uses the time axis to reflect the advantages of the state at each point in time in a post-disaster dynamic environment. However, it is still a preliminary concept. Further research is needed on the problem of vehicle routing for emergency materials distribution based on the time-space network model.
Key words: Emergency logistics; Vehicle scheduling; Route optimization; Time-space network model

1 Introduction

In recent years, frequent natural disasters have seriously endangered people's lives and property, social stability, economic development and long-term stability of the country. The Japan-class massive earthquake in 2011, the major debris flows in Zhouqu, China in 2010, the earthquake in Haiti, the 2008 Hanchuan earthquake in China, the Pakistan earthquake in 2005, the Indian Ocean tsunami in 2004, and the European heat wave in 2003 caused major casualties and serious economic losses. The United Nations International Strategy for Disaster Deduction (UNISDR) Secretariat published the 2009 Global Natural Disaster Statistics Report in Geneva on the first day of the month. The report pointed out that the earthquake caused the most serious natural disasters and economic losses in the decade since 2000. In addition, storms and extreme weather also seriously affect human production and life. Since the beginning of the 21st century, the global average of 78,000 people died each year due to natural disasters, which is 1.8 times that of the 1990s. The global economic losses caused each year amounted to 96 billion dollars, more than twice the number in the 1980s. From 2000 to 2008, Asia was the region where natural disasters caused the greatest loss of human lives. It accounted for 84.82% of the total deaths caused by natural disasters in the world. Among them, developing countries are the hardest hit areas resulting from natural disasters.

China is a country with many natural disasters. Every year, natural disasters will bring huge losses to people. At the same time, as the process of urbanization accelerates and the population soars, major cities in China are facing severe challenges. Potential problems and public emergencies continue to emerge, seriously plaguing people's daily lives. After the occurrence of emergencies, various uncertainties (such as traffic congestion, collapse of buildings, destruction of roads, etc.) were intertwined and caused some degree of difficulty for rescue workers. In order to ensure the smooth progress of the rescue work, it is of great significance to thoroughly study the optimization of emergency route selection. For natural disasters, after disasters occur, it is necessary to effectively select the shortest path to transport disaster relief materials on the basis of the analysis of the existing road

network, so that workers and transport vehicles can reach to the disaster area to participate in rescue work at the first time. The Vehicle Routing Problem (VRP) has a wide range of research values in real life. It is very important to look for real-time and efficient algorithms. In the emergency management work, determine the best rescue route or evacuation route, provide material protection for the affected people in the shortest time, and effectively evacuate the people to the safe area, thus effectively avoiding the expansion of influence and maintaining the stability of the social order.

2 Emergency Distribution Model for Disaster Relief

2.1 Literature summary of emergency logistics route optimization

The problem of optimizing the path planning of disaster relief vehicle after VRP in emergency logistics system has attracted the attention of many scholars (YI, 2007; Wang Shaoren et al., 2010, 2011). Haghani et al. (Haghani et al.,1996) and zdamar et al. (zdamar et al., 2004) studied the issue of natural disaster emergency logistics transportation, the former is a definitive emergency logistics network flow model that takes into account the time window to determine the vehicle path, transportation mode and material transportation arrangements, and Lagrange relaxation algorithm and iterative method are used to solve the model. The latter is a time-dependent dynamic transportation problem. An integrated optimization model for multi-cycle, multi-transport vehicle routing problems and multi-variety material network flow problems is proposed. Xu Tianben et al. (Xu Tianben et al., 2002) pointed out the problem of the selection of rescue vehicle paths in the event of a single earthquake disaster and pointed out that the selected path must have both safety and efficiency characteristics. Barbarosoglu et al. (Barbarosoglu et al., 2002) proposed a two-level decision model for helicopter mission planning in disaster emergency rescue. These two levels of decision-making are coordinated through interactive programs and then solved by GAMS software. The tactical layer mainly determines the number of helicopter tours, helicopter deployment and pilot configuration, while the operational layer is to establish the helicopter flight route, relief material loading and unloading, refueling timetable and reprint plan. Since large-scale natural disasters are sudden, destructive, and urgent for emergency rescue, there is great uncertainty in the supply of information and demand for emergency supplies, in the process of rescue, it is necessary to coordinate the balance between the supply of emergency supplies and the inability to accurately predict the needs of the affected area. Sheu Jiuh-Biing (Sheu Jiuh-Biing, 2007) proposed a fuzzy clustering optimization method for emergency logistics joint distribution operations. This method mainly uses fuzzy clustering analysis method and multi-objective dynamic programming model, so as to obtain the optimal emergency supply and distribution strategy. Wang Jing et al. (Wang Jing et al., 2009) analyzed the characteristics of the emergency logistics system and established a mathematical optimization model using a robust planning method, it solves the problem of how to arrange the emergency distribution center site selection and distribution plan under the condition of uncertainty of emergency supplies, and numerical experiments show that it has good robustness. Yuan et al. (Yuan et al., 2009) established a route selection model for emergency logistics and designed a corresponding calculation method. Arun Jotshi et al (Arun Jotshi et al., 2009)studied the optimization of natural disaster relief resources, the optimization model of distribution and itinerary scheduling was established with the shortest delivery time of the wounded and the maximum survival expectation of the casualty as the goal. The problem of parameter setting was studied by assuming post-earthquake cases. Chen Daqiang et al. (Chen Daqiang et al., 2010) studied the problem of multi-objective decision-making with supply constraints under time-varying conditions, and established a multi-objective decision-making model in which the emergency response time is the shortest and the number of rescue points is the minimum in the emergency logistics system, a simulation example was used to verify the validity of the model and algorithm. Zhi-Hua Hu (Zhi-Hua Hu, 2011) established a linear integer programming model for emergency rescue in logistics systems for the design of network flow design and vehicle path optimization for supply chain containers in natural disaster environments, the simulation shows the feasibility and effectiveness of the model. Luis conducted an integrated study of emergency rescue paths and detailed examples of serious natural disasters in recent years, classification and summarization of various types of rescue path papers and the models involved therein provide a great deal of reference value for follow-up research. He Wenwen studied the problem of emergency goods dispatching vehicle routing based on the prohibition of time windows, and provided prohibition time windows for roads and nodes in transportation networks, an integer programming optimization model was established aiming at the minimization of emergency material transfer time. The tabu search algorithm was designed to obtain a satisfactory solution. Liu Yunzhong comprehensively reviewed the research status of the vehicle

routing problem model and algorithm, discussed the vehicle routing problem model and its solution algorithm. Sun Ying took into account the occurrence of potential disasters, established a nonlinear mixed integer programming model for emergency resource scheduling under multipath, and minimized the total amount of time from the resource assistance point to different resource demand points. Zhong Zhixin combined the connectivity reliability and k-short circuit and considered the two indicators of path utility and connectivity reliability to establish a bi-level planning model. From the manager's point of view, the upper-level model was established in the hope that the relief materials would be sent to the disaster-hit areas as soon as possible, and the lower-level model was considered from the user's point of view, expecting the travel time of the individual users to be the least, then establish a deterministic traffic allocation model. Wei Hang combined various variable factors (traffic congestion, weather changes, etc.), established an emergency path optimization model under stochastic time-varying networks, designed the algorithm to solve, and discussed the complexity of the algorithm. Wu Qing used the theory of traffic flow fluctuations to convert the road's comprehensive factors (such as length and traffic flow) into vehicle driving time. Then, the probability of collapse of the building and the risk of road blockage due to the collapse of the surrounding buildings caused by the variable factors of the road were taken into consideration. Thus, an emergency rescue vehicle route optimization model was established when the earthquake occurred. Zhang Jie took earthquake disasters as the background, aiming at the reliability of path travel time, the risk of path blocking, and the complexity of the path (the number of intersections included in the path), a multi-objective planning model for emergency rescue path selection was established, and a genetic algorithm was used to solve the model, which provided a reliable method for the selection of rescue paths. Liu Yang aimed at minimizing travel time and maximizing travel time reliability, and also established a multi-objective planning model for selecting the optimal path before emergency vehicles travel. The algorithm then chooses k path planning algorithm. Zhang et al. analyzed the choice of emergency relief material vehicle transportation routes. Based on the special circumstances of emergencies, the three decision attributes of time, effectiveness, safety, and economy were considered. The mathematic representation of the attribute is performed and the corresponding function is constructed. Then the multi-attribute problem is transformed into a single-attribute decision problem, and the decision plan with the highest expected utility is selected. Liu Yong focused on the optimization of emergency rescue paths, from the two aspects of the evacuation path for people and the emergency material dispatch path optimization, the model was established and the ant colony optimization algorithm was used to solve it, the path weights were introduced into the state transition rule in this algorithm. On this basis, the improvements were made. Gwo-Hshiung built a multi-objective disaster allocation model with the goal of minimizing transportation costs, minimizing transit time, and maximizing satisfaction. However, assuming that the conditions include the road network intact and the path connectivity is normal, it is obviously inconsistent with the actual situation of the road network at the time of the actual emergency. This part is mainly based on the emergency rescue route and evacuation route. The research and analysis of domestic and foreign scholars can be seen that there are many factors to be considered in the path selection of emergency materials. For instance, considering the certainty and uncertainty of the time window, the utility of the material dispatching path and the reliability of the communication, the uncertainty and diversity of the demand, the safety, the economy, the efficiency, and the occurrence of potential disasters. Different targets are selected for distribution under different factors, such as minimizing transportation time, maximizing reliability, minimizing travel time for individual users, minimizing transportation costs, maximizing satisfaction and optimizing route selection to establish corresponding models. The more comprehensive the factors considered in the modeling process, the more reasonable the selected objectives, and the established models are more applicable.

2.2 Research on vehicle routing problems under different environments

2.2.1 Research on Emergency Material Delivery Path under Random Environment

In 2003, Xie Binglei studied the problem of stochastic vehicle routing in his doctoral dissertation. Based on the number of customers and customer demand, the single-loop and multi-loop strategies were discussed. The genetic algorithm and simulated annealing algorithm are designed separately for this problem. In addition, taking the travel time on the route as a random variable, a chance constrained programming model is established for this problem and a corresponding genetic algorithm is designed. Then the related researches on dynamic random VRP problem and inventory path problem of stochastic demand are carried out. In the same year, with the background of wartime transport in the military transport sector, Shi Yufenproposed the optimization of the single-source single-vessel transport path under uncertain conditions. He Fangguo focused on transport problems based on stochastic theory and

fuzzy theory, and established a model of network optimization under uncertain conditions, a genetic algorithm based on spanning tree was designed to solve the fixed-cost transportation problem with random variables. Li Yinzhen studied the problem of constrained networks and stochastic path and fuzzy path under uncertain conditions, and designed a hybrid intelligent algorithm to solve it. In 2012, Zhao et al. considered the random demand vehicle routing problem with time windows in a random environment and established a multi-objective mathematical programming model based on fuzzy satisfaction. A piecewise optimization method based on quantum evolutionary algorithm and particle swarm optimization algorithm is proposed to solve Pareto solution, which effectively avoids the prematureness of the algorithm. The validity of the algorithm is verified by comparison between instances. For the random demand VRP problem, a large amount of literature is studied every year. Liu Guiying studied the vehicle routing problem of stochastic customers and stochastic demand in master's thesis, and calculated expressions based on the expected length of prior sequences under different circumstances. The heuristic algorithm is designed by combining the space filling curve with the exchange search. The result shows that the problem is solved effectively. Because the uncertainty factors in the emergency environment are more complicated, this part mainly organizes the distribution methods and models in the random environment. It can be found that all scholars are based on the general transportation network transportation, on the basis of which some random factors are considered and corresponding optimization algorithms are designed. These complex random factors can also be considered in the transportation network with emergency rescue as the background, then the current emergency rescue model can be further optimized.

2.2.2 Research on Emergency Material Delivery Path under Ambiguous Environment

Deng Xianming et al. used knowledge of fuzzy mathematics to consider the situation of a rescue center corresponding to multiple disaster-affected sites, and set the demand for relief supplies at the affected site as a fuzzy variable, at the same time, an optimization model that minimizes the transport time of rescue vehicles with hard time window constraints is established, and a conservation algorithm is designed to solve the case where the rescue center implements rescue to eight disaster sites. they also considered expanding a rescue point into multiple rescue points in a fuzzy environment, that is, multiple rescue points responding to emergency response transportation optimization problems at multiple disaster sites, treat the problem as a two-stage decision problem, they also selected three rescue sites to provide rescue cases to 12 disaster sites for analysis. In the latest literature search, Ding et al. studied the location-routing problem (LRP) in natural disasters, taking into account the characteristics of multi-vehicle segmentable material distribution. With the goal of minimizing the sum of transit time, a fuzzy dynamic LRP chance constrained programming model was established and a two-stage heuristic algorithm was designed. Wang Xuzhu established a bi-objective fuzzy linear programming model that minimizes transportation time and minimizes transportation costs, and uses the principles of fuzzy number sorting and fuzzy optimization to solve the model. Zhang Qun and Yan Rui established a hybrid VRP model with multiple distribution centers, multiple models, and multiple products based on previous research and proposed a fuzzy genetic algorithm to solve the problem, the fuzzy logic controller is used to realize the dynamic adjustment of the crossover probability and the mutation probability. Finally, the algorithm is simulated and tested. The example shows that the algorithm has good efficiency. Kang Xuhui and Zhen Haibo studied the problem of stochastic fuzzy three-dimensional transportation. The credibility of the theory was used to establish the opportunity-constrained programming model, and their genetic algorithms were used to solve the problem. Cao Erbao et al. considered the VRP of fuzzy requirements, established a fuzzy chance constrained programming model, and proposed a hybrid differential evolution algorithm based on fuzzy simulation. Yang Lixin and Liu Linzhong considered the three-dimensional transportation problem under the fuzzy environment, and established an expectation model with multiple fuzzy variables, an opportunity-constrained model, and a related opportunity planning model, they designed a hybrid intelligent algorithm based on fuzzy simulation and tabu search algorithm. Ge Yue proposed a fuzzy bottleneck transport problem in his doctoral thesis and gave a polynomial algorithm. Zhong Bo et al. proposed a transportation problem in which both demand and supply are fuzzy variables, the idea of chance constrained planning model and related opportunistic planning model based on this problem is proposed. A hybrid intelligent algorithm is designed to solve the approximate optimal solution of the model. This part analyzes that multiple distribution centers, disaster points, models and products may be considered in the emergency rescue process, and a solution model containing fuzzy variables is established for emergency rescue vehicle transportation problems under different fuzzy environments.

2.3 Research on path planning of emergency rescue vehicle based on time-space network model

2.3.1 The Use of Space-time Networks in other Areas

Although the time-space network model does not have used for emergency rescue vehicles, it has been widely used in other transportation fields. Le Meilong This paper designed a flight aircraft model allocation method for airlines by constructing a model of flight model distribution based on time-space network, and passenger spillover function and flight model distribution cost function. The basic idea is based on the known airline flight plan, passenger demand distribution, fleet structure, model number, based on the establishment of time-space network diagram to draw the parameters needed for flight model distribution model. Then, by solving the flight model distribution model, the flight plan configuration scheme that minimizes the total cost of flight model allocation is obtained. Qiu Lu combined the analysis of time-space paths, time-space prisms, time-space cones, etc. in time geography with the time-space network framework in the traffic field, and proposed the description method of individual reachability in the time-space network. This paper takes the traffic infrastructure network as the background and studies the traffic network problem based on the time-space reachability. Taking the traffic service network as an application background and custom bus services as specific cases, the problem of custom bus service network design based on time-space reachability was studied. A general theoretical framework for modeling and solving traffic network design problems considering the time-space accessibility of individuals is formed, which provides a theoretical basis for traffic planning and management based on accessibility. Hao Congli first discussed the relationship between "flow" and "line" in the process of railway freight transportation. Then based on the time-space network graph to analyze the problem of the combination of streamlines, a streamline combined optimization model was established and an algorithm suitable for fast solution was designed. Chen Baiqian combined with the characteristics of China's railway transport organization and management, put forward a dynamic optimization model of empty car deployment with practical application value. Based on time-space network modeling, solving from the perspective of speeding up the turnover of railway vehicles, the time spent on empty vehicles at the station is greatly reduced. Ingmar Steinzen proposed a new modeling method based on the underlying vehicle scheduling problem of the time-space network and solved the synthesis problem by combining the Lagrangian relaxation column generation method. P. Chardaire also used the time-space network to solve the problem of fleet transfer.

2.3.2 Analysis of the Feasibility and Advantages of Time-space Network Model for Emergency Rescue Routing Planning

In the emergency rescue process, the demand for materials after the disaster in the disaster-affected areas is set as a fuzzy variable that changes with time according to the experience of the policy makers, by applying the time-space network model, each disaster point in the affected area is mapped to the time-space network, and it is solved to obtain the optimal solution for material distribution. Taking into account the serious damage to roads in the disaster-affected areas after some natural disasters, there is an urgent need to open up the lifeline within a limited period of time, due to the sudden occurrence of disasters, road repair teams are generally difficult to organize on a large scale quickly and the repair power is limited. Therefore, limited repair resources must be reasonably applied to the affected areas. When applying the time-space network to post-disaster material distribution studies, due to the limitations of time-space networks, most of the transit time between nodes is limited to known constants. In the actual rescue process, the travel time of the road often has a certain deviation or cannot be well predicted, and in the road repair network, the prediction of the road repair time is also a difficult problem to solve. The inaccuracy of repair and travel time often results in deviations of the entire distribution plan, and it is difficult to achieve an overall optimum. Introducing the method of fuzzy or probability into the modeling of time-space networks will be one of the future research directions. In the time-space network model, due to the introduction of the time axis, the number of nodes in the network has increased exponentially, resulting in the rapid expansion of the model scale. For mixed-integer programming problems, the increase of variables often leads to an exponential increase in solution complexity, the difficulty of solving the problem caused by the scale expansion of the model, the model cannot be solved quickly, affecting the responsiveness of the model. In order to effectively apply the time-space network model, how to solve the problem of the time-space network model algorithm is also the focus of future research.

3 Conclusion

Through the analysis of the published literature, it has been found that a great deal of research has been done on the problem of vehicle path planning in the distribution of emergency supplies. Some

scholars like (YI, 2007; Wang Shaoren, 2010, 2011), Haghani et al. (1996), zdamar et al. (2004), and Xu Tianben (2002), Barbarosoglu et al.(2002), Sheu Jiuh-Biing(2007), Wang Jing(2009), Yuan et al.(2009), Arun Jotshi et al(2009), Chen Daqiang (2010), Zhi-Hua Hu(2011), Zhang Yi, Liu Yong, Gwo-Hshiung proposed many new methods in the optimization of vehicle routes. Xie Binglei, Shi Yufeng, He Fangguo, Li Yinzhen, Zhao Yanwei, Liu Guiying and others made a systematic study of the distribution of emergency materials under random circumstances. Deng Xianming, Dai Ying, Wang Xuzhu, Zhang Qun, Yan Rui, Kang Xuhui, Yan Haibo, Cao Erbao, Liu Linzhong, Ge Yue, Zhong Bo and others mainly studied the distribution of emergency supplies in a fuzzy environment. However, in many researches on material distribution methods, there is little mention of the use of time-space network models for the optimization of vehicle routing for emergency goods distribution, the use of time-space network models in other areas of transportation has been extensive. For example, Le Meilong applied the time-space network model to the allocation of flight models, Hao Congli used the time-space network model for the optimization of railway freight transportation and Ingmar Steinzen used the time-space network model to optimize the vehicle scheduling problem. It can be seen that the time-space network model can be used to optimize the problems in various traffic areas. It is also possible to consider the use of time-space network models and the optimization of emergency material distribution methods. At present, some scholars have proposed the use of time-space networks for disaster relief, but they have only theoretically analyzed their advantages and feasibility, and have not proposed how to use time-space network models to optimize the distribution of materials, researchers can do further research in this area. Applying the time-space network model to emergency logistics, based on the previous research, we further optimized the routing problems in the emergency material distribution process, making it possible to have a more efficient and feasible material distribution plan after the disaster and improve disaster relief capabilities.

Research on the Community Health Service Centers in China

Huang Yumeng, Wu Ningjie, Qiu Yinggui
School of Management, Hubei University of Chinese Medicine, Wuhan, P.R.China, 430065
(E-mail: 807814038@qq.com, wulj310@foxmail.com, qiuyinggui@126.com)

Abstract: The low rates of visit willingness and utilization of medical service in the Community Health Service Center (CHCs) are dual problems need solving urgently. In this article, statistical analysis of data is collected from announcements in official websites of NationalHealthCommission of the People's Republic of China, relevant literatures, and expert consultations. The reasons for being unappealing, inefficient andunprofitable of the CHCs are analyzed from three aspects: factors of consumers, own construction of CHCs and medical service system. The CHCs could give full play to the basic role to solve the difficulty and high cost in getting medical service though correct guidance for consumer's cognition, improvement in medical service quality, strengthening of management and increase of government investment.
Key words: Community health centers; Poor attractiveness; Unclear positioning; Suggestion

1 Introduction

Communityhealthcenters (CHCs) are powerful tools in the three-tier system to guard the basic health of people and make it feasible that people all can get comprehensive, equitable, and affordable healthcare. There is already a great deal of researches and explorations for the development of the CHCs, which aim to promotethedevelopmentandmakefulluseofthemedicalcapacitiesofCHCs. By the comparison of three CHCs models, it has been pointed out that the patients prefer CHCs with more medical staffs and more adequate financial input (Li Het al.2015). The reason of the higher utilization rate for hospital than CHCs is also the difference of allocation in financial capital, which requires the government to increase financial input as a powerful measure to improve the utilization rate and health equity of CHCs (Pan Xet al.2006). It is consistent with the above conclusion that consumers choose to visit hospitals instead of CHCs because of the higher medical level and better reputation of medical staffs (Jun Yet al. 2008; Song Jet al.2015), which indicates that more medical staffs with good attitude and cognitive ability should be assigned to CHCs(Wang Yet al.2006). The research shows that the establishment of the assessment mechanism can effectively promote the development of community service (Mei Jet al.2016), and the lack of a systematic and efficient performance assessment system could result from inadequate utilization of the feedback information to set the future plan in CHCs (Wong STet al.2010). It is intriguing that some studies which measured consumer satisfaction with CHCs services prove the relationship between patient satisfaction surveys and improvement in medical services (Li Zet al.2012; Wu Jet al 2016), and turn my attention to the consideration for the neglect of the mental features and behaviors of potential consumers. Researchers have been focusing on improving the function as first level safeguard of CHCs，there is no doubt that their achievements value a lot and do contribute to the development of CHCs while they both only explore the way out by dealing with its own problems ,trying to solve difficulties through perfection of management framework, optimization of medical treatment resources disposition and better medical ethics construction .The dilemma of CHCs can't be overcome only by self-change or fitting itself to the various and diverse types of needs, it is merely impossible to reach the expectation of people in time which is dynamic and always raises at a faster rate than the development of CHCs. Meanwhile the majority of researchers study the problems of position, service level and willingness to see a doctor based on the professional technical index, while this article discuss the current problems from the perspective of Community residents. Medical services consist of three parts, service providers, service consumers and the objective environment (competitors and national policies). There is a need for efforts of both three part, understanding of consumer which is subjective and the key point of consumers' decision whether to believe in CHCs or not, along with development of CHCs and support of government are integral to the final success. On the basis of the three parts, this article puts forward corresponding suggestions for improving the attractiveness and utilization of services. The CHCs mentioned here are defined as comprehensive grass-roots health service institutions with reasonable distribution which meet the needs o f community residents and community health service function, having beds for rational number and suitable types, aiming to solve community health problems and meet the needs of basic health care services, aimed at solving the community health issues and reach the standard of basic medical and health service, and providing

prevention, health care, health education, family planning, medical treatment and rehabilitation by professional technicians. In recent years, the government at all levels has increased the construction of CHCs and provided convenient and basic medical services for the community population. However, the community health service center still has the problems of being unappealing, inefficient and unprofitable, which must be analyzed and improved.

2 Existing Problems
2.1 Basic situation of CHCs from 2016- 2017

The gap between the community health service centers and other institutions in terms of number of visits still exits, and the index reflecting the performance and efficiency is unsatisfactory.

Table 1   Service Quality of Medical Institutions

	Number of visits（ten thousand）			Number of discharged patients（ten thousand）		
	2016	2017	Growth rate（%）	2016	2017	Growth rate（%）
Tertiary hospitals	142221.5	152430.9	7.2	6639.7	7365.9	10.9
Secondary hospitals	110332.0	115023.3	4.3	6804.8	7160.7	5.2
Basic hospitals	18518.2	19543.7	5.5	866.8	964.9	11.3
CHCs	61335.0	65188.8	6.3	307.6	301.4	-2.0
Township health centers	92073.2	93062.7	1.1	3279.9	3407.1	3.9
Clinics	54630.0	56570.0	3.6	-	-	-
Village clinics	174200.0	169670.0	-2.6	-	-	-

Table1shows the number of visitsof CHCs in 2017 was 6.3% higher than that in 2016, but the gross number is 613.35 million lower than that of other medical institutions .The discharge patients' number is an important indicator of the achievement and efficiency of medical work yet displays a negativegrowth(-2.0%).

Table 2   Beds Utilization of Medical Institutions

	Beds utilization rate（%）		Average length of stay(day)	
	2016	2017	2016	2017
Tertiary hospitals	99.1	99.2	10.1	9.8
Secondary hospitals	85.7	86.1	8.7	8.7
Basic hospitals	61.8	61.8	8.5	8.4
CHCs	55.9	56.7	9.6	9.6
Township health centers	62.1	63.2	6.5	6.6

Table 2shows that the Bed utilization rate of CHCs is only 56.7%, and the average length of stay(9.6 days)which reflects the medical resources utilization and qualityhaven'tbeen effectively controlledand shorten.

Table 3   Number of Medical Institutions 2017(one)

	2016	2017	Increment
Basic hospitals	34444	34422	-22
CHCs	36869	36639	-230
Township health centers	202230	212054	9824
Clinics	642091	637814	-4277

Table 3 shows that the number of CHCs has decreased by 22 over the previous year.

Data above shows increase in the number of visits in CHCs. However, there are great differences in both number of visiting patients and the discharged patients relative to the secondary and tertiary hospitals, even with township health centers at the same level, along with the low rate of beds utilization show the poor willingness for visits and the lack of attraction in CHCs. The number of discharged patients reflect that the opening beds and the beds turnover are insufficient (the number of discharged patients is the product of open beds and beds turnover), as well as the average length of stay supposed to be reduced showed that the medical technical level, quality, effectiveness and efficiency of CHC s are in

need of improvement.

Surveys carried out recent years in Guangzhou，Wuhan，Beijing，Urumqi(Li li et al. 2015;Li na et al. 2016; Ni Nana et al. 2016; Zhang Xin et al. 2016)both reflect low willingness to see a doctor in CHCs and the same problems above.

3 Analysis

3.1 Analysis from consumer's aspect

3.1.1 Consumers' incomprehension of CHCs' orientation

Consumers are not clear about the purpose and significance of hospital grading and the accurate positioning of CHCs in the three tiers of hospitals(Zhu Xiaofeng et al.2017).The conventional thinking ofmost people is that the purpose of grading is to rank hospitals, and they subconsciously to put the tertiary hospital first in the hierarchical medical system and assume the CHCs at the bottom of the system whose medical level and service attitude almost all aspects are poor, cannot provide excellent medical services and protect patients' life safety (Lai Wenchun et al.2016;Wang Yali,2015;Zhang Anqiet al. 2018;Tian Ye,2016). In fact, the grading of the hospitall is not equivalent to the actual hierarchy, only the classification of the disease's light, heavy, slow, urgent and the difficulty of treatment, to realize the reasonable allocation of different medical tasks to the corresponding hospital. Different medical institutions provide targeted medical services in a targeted manner, develop their respective strengths, and divert patients to seek medical treatment in order to achieve effective utilization of resources.

3.1.2 The halo effect of consumers

Before receiving the diagnosis and treatment of the CHCs, what information consumers can capture is the scale, appearance of the hospital, and hospital's visits amount through observation ，then the service attitude and professional degree by communicating with the staff and doctors in a short time. By comparing this information with other hospitals to form a preliminary judgment on the community health service, the initial jndgement of the CHCs is superficial, partial and cannot represent a whole. Relatively speaking, it is true that the scale of the CHCs, the technical equipment, the physician resources, the quantity and the quality is inferior to the larger hospitals, but this is due to positioning, and there is no problem in meeting its prescribed medical tasks. After the CHCs give a very bad first impression, the effect of halo was takes effect, and the bad impression is spread across all aspects of the hospital (Li Zhengquan,2008), then the consumer form a conflict psychologyand no longer willing to go to the CHCs for medical treatment.

3.1.3 Customers' herd behavior

Herd behavior exists obviously in seeking medical treatment as such special consumption activities that are associated with simultaneous expenditure of time and money ，whose treatment results are closely related to the most basic physical health. We are more willing to collect more information and listen to more advice before making a choice, besides the hope of eliminating the pain and restoring health through treatment, we expect to get a sincere and friendly service, maintain a harmonious relationship with the doctor and spend every penny on the edge of the blade (Zhao Ling,2008). The large hospital has always been the choice of most people, whether it is to seek advice from the people around or to consult the medical advice on the Internet，more information is directed to the large hospital. When obtaining enough information along with the function of guidance of mass behavior, patients will be more likely to rely on the large hospital for medical treatment.

3.1.4 Information asymmetry between consumers and Medical institutions

Medical itself is a kind of professional service with information asymmetry. There is a gap between consumers and physicians in the understanding of professional knowledge. The professional knowledge acquired by doctors and nurses comes from years of systematic study and practice, and it has repeatedly consolidated and improved to maintain advanced nature (Zhao Ling,2008). Consumers may know nothing about medicine, that is, they have browsed quite a lot of advice, learned enough information, still could not achieve informational equivalence with medical treatment providers. Many people even can't distinguish through the doctor's explanation of the illness what priority the situation rated, which makes it difficult to make objective and accurate judgments on medical services (Zhou Jianguo et al.2016).Therefore, many patients develop small diseases chose to go to the big hospital. As a layman, patients are not clear about the boundary between light disease and severe, big disease, they can't estimate what on earth the disease is, whether the illness is urgent, to which stage it has developed. In this case, the large hospital is the first choice for the majority of people, they hold the view that rely on the large hospital when you're not feeling well will never go wrong, so as to avoid going to CHCs

finding no access to the needed medical service ,resulting in the final transfer back to big hospitals, such a setback can not only waste time and money but also may cause failure to be diagnosed and treated in time.

3.1.5 Consumers live in Relationship society

People prefer to use interpersonal relationships everywhere in their lives, and they are accustomed to bringing about solutions to all problems through interpersonal relationships. Regardless of what they do, they like to create extra emotional bond in addition to accomplishing things. The more impactful contacts the better, the wider coverage the better. Whether it is clothes, daily necessities or service goods, as long as the quality is guaranteed, they will give priority to the providers with whom they have established relationships in order to enjoy the relaxation of familiarity, and to believe that nepotism can bring better attitudes and services, even better quality goods and more favorable prices (Chen Yanlin,2014).At the moment, emotion is the choice motivation, while transaction itself no longer matters. All the time, people have chosen to get medical treatment in the large hospital, the establishment of relationship net is more rooted in the large hospital, and then the olive branch is extended to the general population, which boosts the growth of the relationship net, forming a cycle of strengthening. When the relationship net of CHCs is not wide enough and solid, if the service provider is selected through a net, the result will be a large hospital.

3.2 Analysis from CHCs aspect

3.2.1 The positioning of CHCs is not clear

The functions of the CHCs include six integrated services: prevention, medical treatment, health care, rehabilitation medicine, health education and family planning technology guidance. However, in practice, many service centers do not fully develop comprehensive services, leaving patients with the impression that they can only treat minor ailments like cold, provide services as infusions and medications. Many patients do not even know that CHCs can provide hospitalization services. The CHCs, which is supposed to be closest to the residents, taking into account the daily medical and health needs of the residents, fail to manifest the advantages of favorableness and convenience for the residents ，meanwhile its resources have not been fully utilized and potential haven't been brought into full play. There are pharmacies to get medicines, and private clinics can provide infusion service, CHCs can do more than this, they should be able to identify their own status and to be distinguished from other institutions, embodying professionalism and comprehensiveness (Sun Jiali et al.2018;Tian Ye,2016).

3.2.2 Lack of human resources

The gross number of doctors in CHCs is quite depressing, and there is a lack of elite doctors. The primary reason is the imbalance between the rewards and efforts of the work, apart from this there is a shortage of resources, technologies, and equipment in the CHCs, as well as the lack of operating funds ,thus they cannot create the conditions for full use of wisdom and skills or opportunities of further improvement for willing employees. Last but not least, compared with large hospitals, the entire medical environment and technical qualification are inferior, the risk probability of medical accidents will consequently increase, in consideration of the tense relationship between doctors and patients and part of the patients are at daggers drawn with their doctors, tragedies can be triggered at any moment, in which case doctors can't be too evasive about medical accidents. In summary, the CHCs lacks the conditions for retaining qualified personnel (Zhang Mingyan et al.2016;Tian Ye,2016).

The allocation of general practitioner (GP) in CHCs is far from enough. General practitioners are generalists who deal with common diseases, frequently-occurring diseases, and general acute illnesses in the form of clinics. Another feature of GP work is home-based services, general practitioners often take care of family patients in the form of home visits, and establish their own family beds and medical records according to the patients' different conditions. General practitioners are still a relatively new concept. The training system is still immature, deficient in corresponding incentive mechanisms (Zhang Mingyan et al.2016), and has not yet been understood by the general public. However, the general practitioner is the necessary staffing for the CHCs.

3.2.3 Particularities of medical and health services

Providing medical and health services is the basic function of the CHCs. As a special commodity, medical services have severe information asymmetry and the characteristics of lacking of elasticity in price elasticity of demand. First, information asymmetry shows that the patient does not understand the medical expertise, and the same kind of service is provided to different patients, differences in service effects are due to gender, age, physical quality, living habits, and the objective environment. Even the same disease may adopt different items for individual health care. No evaluation criteria for health

services has been formed yet, accordingly patients are unable to make objective and accurate evaluation of doctors' medical and health services. In addition, the research on health economy in foreign countries shows that the coefficient of the price elasticity of demand is lower than that of other industry goods (service) (Lai Wenchun et al.2016). The demand of most medical and health services is inelastic and does not change obviously because of the tiny change of price. The patient won't choose a CHCs that has not yet won its trust over a slightly favorable price.

3.3 Analysis from medical and health service system aspect

3.3.1 Health care financial input

The financial investment taking up the bulk of operating fund is the premise of the construction, the fundamental foundation for the initial operation of the CHCs, and the key factor for the public welfare. Only when well built up to get the trust of the people, and complete their cardinal function treating the patients,can the CHCs give full play to the basic medical service function, actualize the income of the functional tasks, make it possible to turn around, and keep the normal operation and continue to build on this basis(Zhu Xiaofeng et al.2017). In fact, the state emphasizes the well-being of the people's livelihood, paying more and more attention to the medical and health services, and committed to make the public get better medical services and more equalized public health service. The investment of the state finance is increasing gradually, but the proportion in the financial expenditure is still lower, which is far from enough for the CHCs when allocated by layer distribution (Zhang Mingyan et al.2016).

3.3.2 Uneven distribution of medical resources

All along, the uneven distribution of medical resources in China is a salient problem, there are significant disparities in the distribution of health workforce (Chen R,2014).The CHCs is much worse than the secondary and tertiary hospitals, both in terms of technology and human resources, Secondary and tertiary hospitals continue to attract more excellent resources by virtue of their advantages, the gap between them and the CHCs is thornier to narrowed (Sun Jiali et al.2018). Medical resources occupy an important part of the hospital; it is the material basis of providing medical services. The full and high-quality medical resources are the indispensable guarantee for the good and smooth medical service delivery.

3.3.3 Competition in health service market

The implementation of medical reform has enabled the drug zero addition to be completely put into effect. The use of drugs to nourish medical care-the income of medical institution mainly come from drug selling - has always been an odd phenomenon in China's medical market. Before the medical reform, most of the hospital's income, apart from financial input and medical service income, came from the profits raised by drug markup. It is necessary to adjust the price system of the medical service and improve the price of medical service to adapt to the change of the income structure by abolishing the drug markup, actualizing the zero difference of the drugs and cutting off one of the three income channels of the hospital .While this adaptation process takes time, the number of patients will not diminish by the zero addition of drugs, the large scale of the patients also requires the increase of the size of the large hospital, and the survival and development of the hospital depends on its business income, which makes large hospitals increase the number of medical services while increasing the price of medical services ,thus strengthening the competitive relationship between the hospital and the CHCs in basic medical care(Lai Wenchun et al. 2016;Tian Ye 2016).

4 Suggestion

4.1 Keeping information open to consumers

By providing sufficient information to establish a foundation for consumers' trust. We are in the information era; new media is the strongest medium for the dissemination of information. CHCs can adopt new media technologies, establish an open information platform through web pages, WeChat and Weibo accounts to provide people with access to enough information relevant to the CHCs, clarify the positioning and functions of the CHCs so that consumers can understand what services the CHCs can provide, correct the subjective one-sided judgment that the CHCs can only provide infusion and medicine , and guide the masses objectively understand CHCs and abandon stereotypes, the same time pay attention to the masses' attitude, eliminate the doubts and worries of the masses through continuous interaction to increase willingness to get treatment in CHCs, make the best of feedback effect using method to trace the patient's medical experience survey, listen to the patient's personal feeling , based on which to improve the construction of CHCs.

4.2 Strengthen the construction of CHCs

4.2.1 Define the positioning of CHCs

CHCs must be accurately positioned. Compared with the secondary and tertiary hospitals, though the CHCs cannot solve the complicated and difficult diseases, it should carry out all the basic medical and health services for which it is responsible, throughout the whole process of disease prevention, treatment and rehabilitation, and focus on its own professional work, make a difference in the responsible field, so as to achieve the basic guarantee of the health of the residents.

4.2.2 Fundamentally Improve the Professional Service Capability of CHCs

CHCs in China started late, and all aspects are still in continuous improvement. The fundamental task of medical institutions is to provide prevention and treatment of diseases for patients .The ability to provide professional medical services is at the core of medical institutions, so CHCs should enhance the professional level of medical services, strengthen management and train professional general practitioners to ensure the quality and efficiency of service delivery, meanwhile enrich and update the technology, equipment and drug resources of the CHCs, shorten the average length of stay, and effectively increase the utilization rate of medical resources to provide a solid material foundation for the provision of medical and health services.

4.3 Actively seeking a way out in the health service market

4.3.1 Carrying out the responsibility of financial input

The CHCs has the nature of public welfare. If the total income depends on medical income, it will violate the characteristics of its gratuitous nature. Government should increase its financial input, set allocation structure right, and fully support the community's health infrastructure construction, technical equipment allocation, and medical personnel training in all aspects, so as to promote the community to expand service coverage and achieve equalization of public health.

4.3.2 Explore cooperation models with public hospitals

Policy alone is not enough to alleviate the tense competitive relationship between CHCs and large hospitals. The establishment of a suited mode of cooperation to solve the conflict of interest, along with the formation of resource sharing and sinking, can effectively relieve the pressure of the secondary and tertiary hospitals and encourage the development of the CHCs in the health service market.

4.3.3 Developing characteristic medical services

In recent years, the green diagnosis and treatment (non-drug treatment) has entered the public's field of vision. It carries out treatment with traditional Chinese medicine, such as Chinese medicine patch, diet, massage, cupping and so on rather than take medicine or provide infusion. It is especially popular in children's diseases, chronic diseases and geriatric diseases. For some patients with mild illness, long course of disease and special diseases, gentle and gradual treatment of Chinese medicine is a good choice. The CHCs can set up a combination of Chinese and Western diagnosis and treatment structure in this trend, and distinguish itself from diverse medical institutions with its uniqueness.

5 Conclusion

The development of community health service center is of profound significance to the grass-roots medical care of the country. It is an important measure to effectively solve the problem about the difficulties and high costs of public medical care. Joint efforts among the government, health administration department, CHCs and public are needed for the further development of the CHCs to give full play of the basic role for CHCs, and achieve satisfaction of the masses, medical institutions, and the government.

Construction of Psychological Crisis Student Case Management Service System in Chinese Universities

Liang Yusong

Mental Health Education Center, Wuhan University of Technology, Wuhan, P.R.China, 430070

(E-mail: 715770277@qq.com)

Abstract: By using the methods of literature research and comparative study, this paper puts forward that the case management team should be introduced into the psychological health service of the psychological crisis students in Chinese universities. It is believed that the case management service object in Chinese universities should include students with the suicide risk, ones with the psychological diseases and ones with the history of psychological disease treatment, and the case management team should be led by case managers, counselors, psychiatrist, ideological and political educators andschool leaders at all levels. A case management service system is constructed, which includes psychological evaluation, formulation and implementation of the programs, effect evaluation and improvement. It is concluded that the construction of a case management service system for psychological crisis students which is in line with China's national conditions will help to maximize the effectiveness of mental health services.

Key words: College students; Psychological crisis; Case management service system; Construction

1 Introduction

The term "case management" appeared firstly in the law of education of disabled children was promulgated by the federal government of the United States in 1975 (Ye Mengzhu, 2003). Its emergence is one of the most important advance in the field of human services. About the case management, different scholars have different opinions. Such as, the Case Management Society of America(CMSA) proposed that case management is a process of cooperation, including evaluation, planning, implementation, coordination, supervision and evaluation of selected services, It can meet the overall health needs of the case owners, improve the service quality and the cost-effectiveness through selecting reasonably the available resources and communication (CMSA, 2013). Hangan believes that case management is a way of focusing on work, highlighting priorities, reducing intermediate roles and processes in a team-cooperative way, based on the applicable target customers and resources, which can improve the experience of the client and their families in mental health services (Hangan, 2006).Xiu Huilan, a Taiwan scholar, believes that case management is the communication and coordination of the staff of different organizations, providing the necessary services for the client by teamwork, and expanding the effectiveness of the service (Peng Lu, 2014).It can be seen that case management is the process of providing service for the client by team members of different organizations. The process includes assessmrnt, planning, implementation, coordination, supervision and evaluation, which aims to achieve the docking of the client and the required resources, and to ensure the continuity of the service, so as to maximize the interests of the client.

Case management, as a management method to provide specific services or resources for service objects, firstly appeared in social work and clinical nursing. In 1960s, case management was introduced into the mental health service industry and gradually became a common way of providing mental health services to specific people worldwide. Research shows that case management services for patients with mental illness can effectively improve patients' treatment satisfaction and mental health treatment rate.Ziguras's cluster analysis of 44 mental health case management studies from 1980 to 1998 showed that case management has three advantages in family burden, family satisfaction and nursing costs;In addition, case management has obvious effects in reducing symptoms, increasing doctor-patient contact, reducing the rate of shedding, improving social functions and patient satisfaction(Ziguras,Stuart,2000). Bender's linear regression analysis of 3 data sources suggested that case management service is an effective tool to leave young people in mental health treatment, because it reduces service access, achieves multiparty coordination, and establishes a relationship between the customer and the liaisons, which can raise the mental health treatment rate of individuals and groups (Bender, Kapp, Hahn, 2011).Liu Xiangming and others have found that the use of case management mode for schizophrenic patientsin the community can improve their quality of life and self-care ability (Liu Xiangming, Liu Cuimei, Wang Dong, 2011). Xu Weiya's study found that the implementation of case management for patients with bipolar disorder in the community can effectively improve the social function and the

condition of the patients and reduce the recurrence rate (Xu Weiya, 2017). Li Zhilin and others think that case management shows the pattern of team cooperation and resource integration,and introducing case management into the field of mental health service in universities has unique advantages in dealing with difficult cases, especially crisis cases(Li Zhilin, Zhang Jiyu, Wang Qing, 2017).Yang Rui's research finds that students with learning disabilities can change their self-cognition, bad habits and improve their personality development by using the method of case management (Yang Rui, 2017). Therefore, by using the method of literature research and comparative research, this papertrys to make a comparative study on the status of psychological crisis case management service in universities at home and abroad. On this basis, this paper studies the service object, team composition and service process of the case management of psychological crisis students in China, aiming to construct a case management service system for psychological crisis students, which is in line with China's national conditions.

2 Comparative Study on The Current Situation of Case Management Service in Universities At Home and Abroad

In the United States, there have been many theoretical and clinical studies on how to implement case management in school mental health services. Such as, Terry, an American scholar, puts forward his own views on the composition and operation mode of case management team.He believes that the core staff of a case management team should be made up of a wide range of school staff and other health services associated with the need, which includes school leadership, student service / pastoral care staff, school psychologists or consultants, clinical psychologists, clergymen, social workers and young workers, and so on. At the same time, the role and responsibility of the members should be clearly defined.The case management team operates as a consultative team, such as regular meetings, sharing of goals and interventions designed for students, responding to critical events and planning preventive measures, and establishing alliances with some institutions to promote the participation of these institutions,etc.(Terry, 2006).In the mental health service of the Philadelphia University in the United States, the objects of case management include students with mental health problems, ones with alcohol and drug abuse, ones with behavioral disorders, and ones with academic problems or violent tendencies.Case management is the most distinctive team work at counseling and psychological service center of Madison University in Wisconsin, United States. Its main functions are evaluation, planning, consultation, monitoring and referral, that is, to discuss the students to be concerned, to make suggestions, and to make plans. It involves a variety of fields and levels, and consists of working groups with different expertise.In their case management system, different specialized psychological providers work together, keep in touch, and the case manager keeps in touch with the external professional institutions and community service providers, whichensures that the team can continue to understand and grasp all the circumstances of the case.At the same time, the team maintains effective links with the student management department or staff, such as the educational service department, the student department, the dormitory management department, the student family, the community service organizationetc., in order to realize the student information collection, summary analysis and joint processing(Li Zhilin, 2018).

In China, how to carry out case management in mental health service of universities is still in its infancy, and there is not much theoretical research and practical exploration in this area.Such as,Li Zhilin and others think, the object of the case management service in Chinese universities should include students with problems of safety and stability, ones with past history of psychotherapy, ones who need psychotherapy, ones who need to be transferred to the outside psychological service or be transferred to the school from the outside psychological service, and ones who need additional support and service or do not belong to mental health services but still need help. The case management team should consist of case managers, assessors and crisis intervention personnels (Li Zhilin, Zhang Jiyu, Wang Qing, 2017).Wang Shaowen pointed out that the procedure of case management for students with psychological problems should include the following steps: identifying the case owner, establishing a relationship with the case owner, assessing resources and diagnosing, formulating service plan, obtaining internal and external resources, coordinating resources and ending service (Wang Shaowen, 2014). By using the method of grounded theory, Peng Lu found that the case management of mental health services in 9 universities in Hubei Province was not perfect, and most of their service object were students with serious mental illness or suicide risk(Peng Lu, 2014).From table 1, it can be seen that in the composition of the case management team, there are no extra school professionals, especially the psychiatrist, as a member of the team; in the setting of case managers, there are no special case managers in 5 universities;in terms of the case management process, none of the nine universities

surveyed had developed an independent plan or had a rigorous evaluation of the effectiveness of the program..

Table 1　The Status of Case Management In Nine Universities Surveyed

University code	professional of outside school	Full-time psycho-logical teacher	case manager	Case management plan and effect assessment
A	no	having	having	no
B	no	having	no	no
C	no	no	having	no
D	having	having	no	no
E	no	having	having	no
F	having	having	no	no
G	no	having	having	no
H	Unknown	Unknown	having	no
I	no	having	no	no

Through the comparative study of the present situation of case management service in universities at home and abroad, it is not difficult to see that in the case management service object, the service objects of foreign universities are more extensive, which include students with psychological problems and ones with academic problems or other problems, but the service objects of Chinese universities are mainly students with psychological diseases or Suicide risk; In the composition of the case management team, the team of foreign universities consists of the professionals in all aspects,but the team of Chinese universities is mainly limited to the staff within the school and lack of the use of outside resources; In the case management service process, foreign universities have a very rigorous, professional and perfect service process, while the service process of Chinese universities is not professional and perfect.

3 The Service Object, Team Composition and Service Process of Case Management of Psychological Crisis Students in Chinese Universities

Comparing with the mature experience of case management in psychological health service of foreign universities, we find that the case management of psychological crisis students in Chinese universities should be defined and perfected from three aspects: service object, team composition and service process, so as to provide more professional and effective psychological health service for psychological crisis students.

3.1 Identify the service objects of case management of psychological crisis students

Theservice objects of case management of psychological crisis students　in Chinese universities mainly include the following kinds of students:

Students who have hidden dangers of life safety. When students are in danger of injuring themselves or hurting others, the first is to ensure their safety of life and directly contact the psychological crisis experts to evaluate them, and to bring them into the case management team to discuss its acute, danger and stability, so as to determine the further measures which include direct crisis intervention, transferring to hospitals or professional institutions, etc.

Students with a mental illness. When students suffer from psychological diseases such as depression, schizophrenia, or bidirectional affective disorder, they should be brought into the case management team and be treated with drug treatment and psychological counseling.

Students with a history of mental illness. For those who have been hospitalized or out-patient for mental illness, they should also be brought into the case management team.

3.2 Define the composition and function of case management teamof psychological crisis students

The functions of case management in university mental health service include resource integration, crisis management, psychological assessment and referral. In order to perform its functions, the university should have a fixed psychological crisis student case management team, and every professional in the team should have its functional requirements. Specifically, the composition and functions of case management team are as follows:

The first is the case managers. This is the core of the case management team. The case administrators of college psychological crisis students　are best equipped with full-time teachers of mental health education. The main functions are to evaluate the psychological situation of the psychological crisis students , to formulate individual case management schemes, to assist students to

connect with the resources in the school and outside the school, to follow up the referral students, to coordinate the inpatient students, and to find all kinds of resources and support. In addition, the case manager is the coordinator of the whole team, is responsible for the convening and process of the case management meeting, the sorting and integration of all kinds of information, and the communication of different personnel and departments.

The second is the counselors. Their main function is to provide psychological counseling for students. When necessary, they will communicate with the case manager after obtaining the consent of the students, so as to seek more resources and support for the students.

The third is the ideological and political educators. Ideological and political educators are the staff of Chinese universities to carry out ideological and political education and daily life learning management for students and to organize students to carry out various activities, including scientific, technological and social practice activities. In the case management of the psychological crisis students, their main function is to talk with the students regularly, to understand the students' psychological dynamics, to help the students to solve the problems in their study and life, and to urge the students to insist on drug treatment and psychological counseling.

The forth is the psychiatrist. Its main function is to diagnose and treat students and provide regular referral services to students.

The last is the school leaders at all levels. They include leaders of the leader of the student affairs office, deputysecretaries of departments, and presidents of school hospitals. Their main function is to provide resources for students.

3.3 Formulate rigorous, professional and perfect service process of case management of psychological crisis students

In the author's opinion, by drawing on the experience of case management in foreign universities, the rigorous, professional and perfect service process of case management of psychological crisis students should include fourlinks, such as psychological assessment, formulation scheme, implementation scheme, effect evaluation and improvement.

The first, evaluating students' psychological problems.The participants in this link are mainly case managers and psychiatrists. When a student has a psychological crisis, a case manager needs to make a preliminary assessment of its psychological condition. If it is found that a student may suffer from mental illness, he or she needs to be transferred to a psychiatrist to be diagnosed, and if necessary, students should be recommended for medical treatment or hospitalization. When the students return to school after hospitalization or suspension of school, the psychiatrists first assess the psychological recovery of the students. If the students have basically recovered their mental health, the case manager will evaluate the problems, difficulties and the possible resources that the students may face after their return to school.

The second, formulating a case management scheme. The participants in this session mainly include the leader of the student affairs office, the deputy secretaries of department, the case manager, and the ideological and political educators. When the students confirm their mental health by psychological assessment, the case manager convenes the leader of the student affairs office, the deputy secretaries of department and the ideological and political educators to hold a case discussion, and set up a case management scheme, the sequence and the methods of implementation.

The third, implementing of a case management scheme. The participants in this session include case managers, ideological and political educators, counselors, and parents. In this link, the case manager is mainly responsible for coordinating the resources of all parties to offer the most effective help to the student, keeping in touch with the ideological and political educators and counselors, supervising the implementation of the case management program and doing a record. Ideological and political educators are mainly responsible for supervising student to return visits and to take medicine and regular psychological counseling, and talking with students regularly to understand the practical problems that students may encounter during medical treatment or interpersonal communication in their life and study. Ideological and political educators should communicate with the case manager, and assist the case manager to help the students to solve the actual problems. They should also give full play to the role of the student cadres, let the student cadres care and help students, give emotional support and accompany in their study and life, build a psychological support system for the students, communicate with parents regularly and understand the situation in a timely manner. They also have to do a good job record. The counselor is mainly responsible for regular psychological counseling and consulting records, urging students to adhere to drug treatment, and offering timely feedback on the actual problems and difficulties that students talk about in the consultation to the case manager. Psychiatrists are mainly

responsible for regular referral, timely detection of students' problems and risks, and feedback to case managers. Parents should communicate with their children regularly, give emotional support, accompany, care and encourage, accompany them when necessary, and communicate the problems and difficulties of the children with ideological and political educators in time.

The last, evaluating and improving the service effect of case management. The participants in this link mainly include the leader of the student affairs office, the deputy secretaries of department, the case manager, ideological and political educator, the counselor and the psychiatrist. The case managers organize the relevant personnel to hold the effect evaluation meeting, and evaluate the implementation effect of the case management scheme according to the report of the parties. If the psychological condition of the students is improving, the program can be continued. If the effect is not ideal, then they should discuss the reason and improve the scheme.

4 Conclusion

In China, with the progress of society and the development of the times, students are facing increasing psychological pressure, and the incidence of psychological crisis incidents is gradually increasing.How to provide more professional and effective mental health services for psychological crisis students has become an important task of Chinese universities.As a mode of team cooperation and resource integration, case management has unique advantages in dealing with psychological crisis cases.Therefore, the implementation of the strict, professional and perfect casemanagement in the psychologi-cal health service of psychological crisis students will help to maximize the effect of mental health service. In the future, we should strengthen the exploration and research of the case management service system of the psychological crisis students .

Abstract: This article aims to reflect on how management can be the common pool resources oriented by principles of externalities and property. Thus, the guiding concepts for decision making regarding these two factors were those of the positive or negative externalities generated from the exploration and use of goods as well as the aspects related to the property of resources. Resources may be categorized, as being rivals and / or excluders, and their regularly generate externalities to other social actors in the present, as well as to their own possessors or potential users in the future. Therefore, based on the study of these relationships, could lead to a better decision-making process, concerning ownership of access, and on management as to the preservation and use of common pool resource. Moreover, it is necessary to understand that every resource consumed leads, at some point, positive or negative externalities to other individuals. In addition, the simple monetization of resources does not solve the problem of negative externalities. Therefore, based on the categorization of the property that has to be exercised and the externalities, it is possible to understand how to manage a resource. This situation helps to understand the exercise of control and usufruct of the resources.

Key words: Common pool resources; Externality; Sustainability

1 Introduction

The production and consumption system supply the demands of society by private goods and services. Consequently, it is necessary to exploit resources of the most diverse types for this system function. Thus, when dealing with resources, it can be said that several discussions can arise, mainly because of the advantage in free-market systems has always been to control these resources (Barney, 1991). However, there are some resources that are consumed collectively like the oxygen present in the environment, forests, schools in the seas and rivers, game animals, public parking spaces, streets and public avenues etc. (Ostrom, 2000; Ostrom, 2008; Hardim, 1968).

To discuss the use of resources is necessary understood how the ownership and management of these resources are. Although there are resources that are privately owned, there are also resources of property and common use such as those mentioned above and those are of collective use and are called common pool resource. We can say that based on the relationship between the availability and the use of these resources is that socio-environmental conflicts occur. In this way, the problems generated by the common pool resource come from their scarcity, which is increasingly frequent due to the crisis in their normal rate of regeneration, which is caused by economic action (Libiszewski, 1992). On the other hand, actions that impede the capacity of resources of resilience make the discussion about common pool resources emergency.

Common pool resources can be understood as the set of benefits that are shared by all members of a society, or at least most of them. This feature is also called the common pool resource. It is worth mentioning that this is a shared economic good, independent of any system of legal property rights (Ostrom, 2000; Ostrom, 2008; Hardim, 1968).

Starting from the reflection on the private goods and the common goods this article aims to reflect on how the common pool resources can be managed. For this purpose, it is argued here that by understanding better how the externalities of the use of these resources are generated, a guiding bias can be established to make decisions regarding their use. Although this topic has already been discussed by Hardin (1968) e Ostrom (2000; 2007; 2008), this topic still has relevance of being treated in order to contribute with the understanding and diffusion of the subject.

2 Common Pool Resources and Externalities

2.1 The property right on the goods

Individuals to meet their needs and desires need goods and services that are produced or available in nature. It is worth mentioning that the use of natural resources such as wood, ore, among others, occurs even for manufactured products. Besides, when it comes to production, it is necessary to remember that the production or transformation of natural resources, as well as their consumption, generate waste that will be sent back to the common environment – common pool resource. In the same way, when you remove common goods from nature you also remove your ability to generate ecological services (Huntsinger& Oviedo, 2014).

To understand the use of common pool resources in society, we must discuss the right of ownership. Thus, we can define in four property categories of common resources, namely: open access, private property, communal property and state property (Feenyet al., 1990).It is worth emphasizing that the property question raised here is related to the ability of the possessor of a good to make decisions and take care of the good; ownership is related to being able to manage to make the good sustainable.

Common resources that have open access are those where there is a lack of well-defined property rights. Moreover, in many cases, the access to these resources is not regulated, and in turn is "virtually" free. Examples of this free access to common resources may be fishing in some lakes or in the open sea, furthermore to the use or pollution of ambient air. In contrast, when private ownership of this type of property is exercised, it may exercise the right to exclude others from using its resources. Being that the case to regulate the use of these resources are invested powers in an entity, that can be an individual or an organization. It should be noted that property rights are generally recognized and regulated by the State (Berkes, 1989).

Another category of property is called communal property. It means when the resource is maintained by an identifiable community as interdependent users. These users can exclude strangers from the community while regulating the use by members of the local community. It should be noted that within this type of society the rights to use the resources are not likely to be exclusive or transferable, the rights of access and use are equal. Some examples of this type of property can be found in some coastal fishing and pasture properties, which are managed as communal property (Berkes, 1989; Ostrom, 2008).

Regarding Public property, the rights to the resources invested are exclusively of the government, which in turn makes decisions about access to resources, level and nature of the holding be regulated. The category of assets may refer to goods of which the public has equal access and use rights, such as highways and public parks. An important point in the nature of the public property regime is that it has the power of coercion of the police to assert its use or exclusion. Another very important point is the generation of revenue to administer state property part of the taxpayer payments through taxes and fees.

Therefore, when introducing the concept of property in the use of resources, it is possible to reflect on the exploration and capture of them. Accordingly, when individuals, governments and companies try to solve order problems related to resources access and exploitation, tends to see two types of solutions. On the one hand, the ownership of resources exercised by the State, occurring the administration and availability of access by government action. On the other hand, private property can be exercised, whether individual or corporate, making use of free competition in the market for regulation in the exploitation of resources (Bollier, 2008; Hardin, 1968). It should be stressed that the maintenance of a property, regardless of who owns it, will need social and financial resources that will be generated in different ways.

Then, based on the preference for private or state property, the discussion about the exploration or management of common property leads to reflection on one's own survival on the planet. This premise is true when we adopt the perspective that resources are all common, because the natural, social and even economic environment suffer from the influence of all the existing actors in society, and to a certain extent on the planet.

Although the management of natural resources is more frequently discussed as common goods, it is necessary to understand that better management of social and economic resources are also important for the well-being of a society. It is a fact that the crisis of 2008 affected every planet when the scarcity of financial resources in some localities. Notwithstanding the crises that occur at the beginning of the 21st century, it is increasingly evident that society is globally interconnected, not only by political, economic and technical systems, but also through biophysical systems supporting life on the planet (Mann, 2017; Morin, 2013; Henderson, 1991; 2003).

Thus, for a better use of resources by individuals, organizations or the State, it is required to understand the relationships arising from their exploitation and supply. In fact, the assets of our economy can be grouped according to two characteristics (Passuello, Oliveira & Mendes, 2009), which are:

a) Exclusion: people excluded from enjoying the economic good, because their access is regulated. Laws recognize and enforce private property regimes.

b) Rival: the use of an economic good by one person reduces the benefits to others.

Based on these two functions and the objectives that individuals seek to meet their needs and desires, goods can be categorized according to their production and consumption (Hines, 2008). This relation of rivalry and exclusion with respect to goods can be verified in table 1.

Table 1   Resources Regarding Their Functions

	Excluding	**Non-Excluding**
Rival	Private Property	Common Pool Resources
Non-rival	Products "Club" (communal property)	Public Goods

Source: Adapted by the authors, 2018 (Hines, 2008).

So, rival goods are those whose use by one person prevents their simultaneous use by another. The goods that are exclusive those whose used by a certain individual, and they can be protected. On the basis of these categories presented in Table 1, four types of goods can be described as follows:

a) Private goods are both rivals and excluders.

b) Common goods (common access resources) are rivals but whose nature makes it difficult or impossible for others to use them.

c) "Club goods" (communal property) are not rivals, but some individuals may be excluded from use.

d) Public goods are neither rival nor exclusive. But, they are difficult to manage when for access to all, as it is usually about the guardianship of the State.

Therefore, reinforcing the idea of management of common goods, it is known that these goods are rivals, but they are not exclusive. Thus, the available commons can be understood as shared resources that a community builds and / or maintains. Examples can be cited: common public resources such as libraries, parks, streets, etc.; common natural resources such as lakes, animals, vegetation, etc.; and common environmental resources such as atmosphere, water and biodiversity (Bollier, 2008). In turn, these natural or environmental goods contain an element of negative externality inherent in having no associated price when they are exploited or used (Passuello, Oliveira & Mendes, 2009).

Another way of understanding common goods is presented by Espeleta& Moraga (2011). These authors stress that the International Forum on Globalization proposes three types of common pool resources:

a) A first type that includes water, land, air, forests, fish stocks, i.e. the biological resources that are necessary for life.

b) A second type that can be categorized as culture and which includes knowledge.

c) The third type which is socially common property. This category is made up of resources which ensure public access to health, education and social security.

Based on these cultural and social dimensions of the common goods a new attitude can be adopted when exploring and consuming common goods. Ostrom& Hess (2007) describe that the ability to exploit what was once accessible generates fundamental changes in the nature of the resource, that is, this type of common good provides a new approach in the property ownership determination. The fact that it modifies this relationship is that these types of commons are neither rival nor excludable. Unlike natural resources, their "intangibility" means that the exclusive property of the good is not exercised. So, sharing is not only acceptable, but also beneficial since it improves its characteristics.

2.2 Exploration externalities and resources usage

As stated previously, people organize themselves in society so that their needs are fully and safely supplied, so that goods and services are needed for their subsistence. In addition, for a given company to function properly, resources must be managed based on a short-term economic vision, but also looking at the sustainability of medium- and long-term resources (Beck, 2014).

In this way, it is worth emphasizing that when thinking about a society one must understand that economic growth and socio-environmental development must always be linked (Sen, 2000). The problem created between privileging the short-term economic to the detriment of long-term

socio-environmental sustainability can be exemplified by the use of a high-value resource such as trees or river water, as their market values often do not account the socio-environmental cost to society due to its shortage.

Therefore, trees cut to make charcoal, furniture and other wooden utensils, as well as drinking water used for expensive washing, backyards, among other uses of little importance to maintain the life of the people, can generate serious damages to the subsistence in the planet (see: Mekonnen& Hoekstra, 2016; Kanemoto, Moran &Hertwich, 2016). It is worth noting that these losses occur on a large scale and accumulate more and more (Brown, 2003).

Thus, in the composition of the market value of the goods, it is often not considered the total costs, present and future, for the use of these resources. So it is admitted that the passing on of these costs affects the environment when its shortage, workers in reducing wages and citizens in the lack of public services or payment of taxes (Bollier, 2008; Sen, 2000; Beck, 2014).

So, in dealing with the use of natural, social or economic resources for the production of goods or services, present and future costs must be taken into account. Although the costs incorporation increases the price of goods, they can still be understood as value aggregators. The reason for this reinforcement is due to a greater awareness of the future availability of resources, despite the fact that the pricing of negative externalities is restricted to a limiting instrumental rationality; this is a form of perception common to all because the concept of environmental value is very loaded with subjectivity.

Therefore, the perception of value in relation to products and services depends on an evaluation of the other based on their personal beliefs and values. To facilitate the understanding of asset values, they are presented here based on three categories (Pearce *et al.*,1989), namely:

a) Value in use - is the value attributed to a good by the user;

b) The value of option - value that they attribute to the permanent possibility of using it;

c) The value of existence - is the value attributed to existence itself, regardless of current or future use expectations.

These approaches help in the evaluation of goods and services in general and of common goods in particular because in determining the use, choice or existence of a good, it determines losses or gains in relation to the consumption of resources in the future. Since the burden of consumption is often not assimilated by those who are consuming in the present, this is one of the main questions about sustainability: Future. Moreover, when the losses of unconscious and inconsequential exploitation of resources are highlighted and understood, the externalities of this process are exposed.

Externalities are represented by the cost or benefit that an agent, in the performance of an economic activity, imposes on third parties. Since this can happen positively or negatively on economic activity or even on another income or welfare economic agent without a corresponding compensation (Coelho, 2012; Gonçalves, & Ribeiro 2013; Cruvinel, Pinto, &Granemann, 2012).

In this way, externalities derived from the actions of an agent in society have natural, social or economic repercussions on resources for all (Eltz, 2012; Coelho, 2012). In a simple way, externalities are costs or benefits that are not included in the present prices of goods and services.

It should be emphasized that civil society, public sector and private sector have a relevant role in the implementation of initiatives that make it possible to maintain the competitiveness and sustainability of the production and consumption system, but that this present state of affairs does not affect other agents or the same agents in the future (Xavier, &Caldeira-Pires, 2004; Caldeira-Pires, Rabelo, & Xavier, 2002).

However, when there is a concern with the externality and it is compensated, it ceases to be an externality, and thus becomes internalized. According to Coelho (2012) two conceptions arise from this concern that try to explain the internalization of externalities. They are the Theory of Welfare Economics and the Theory of Economic Analysis of law. The former externalities would be market failures that the State must correct. The latter, it seeks to reconcile the application of legal norms to standards of economic efficiency (Gonçalves, & Ribeiro, 2013; Coelho, 2012).

Cavalcanti (2004), and Figueroa (2005) question the logic of commensurate with the immeasurable, that is, the use of a metric such as the monetization of all resources and goods indiscriminately. Thus, by monetizing goods in the form of economic valuation of externalities, it may become a trap for individuals, organizations, and the state. This question is related to the transfer by the internalization of natural resources that are not renewable, which generates damages to the society that cannot be recovered like the health of the people or the consumption of goods essential to life.

Therefore, in dealing with the common goods and the generated externalities of their exploitation or consumption it is important to understand that value or value measurement is not something easy, or

in some cases accepted. So, for the administration of common resources in the production of goods and services, it is necessary to base themselves on the concept of inalienability (Bollier, 2008). Since this concept is related to something that cannot be sold, then ownership of the common goods belongs to everyone and to no one, because its use benefits those who consume at first, but harms everyone by their scarcity in the future.

2.3 Externalities and common pool resources

At the beginning of this work we explored the concept of common goods that describes a wide variety of phenomena, since it refers to the social and legal systems that are used for the administration of resources that are shared use (Bollier, 2008). This could happen according to Ostrom (2000) in a fair and sustainable way. This is an idea contrary to what Hardin (1968) thinks, when he emphasized that any system of shared administration inevitably results in a "tragedy of commons".

Hardin (1968) described that a feature when it is free and shared access could ruin its existence. This situation he calls "tragedy of common goods". The author has attempted to prove that, like pasture and livestock of common access, where anyone can raise livestock unrestrictedly and free, property will be led to a common ruin.

According to Hardin (1968), restricted land case may be admitted that shepherds wish to maximize their production and increase the size of the herd whenever it is possible. In this situation, the usefulness of each additional animal has both a positive and a negative component:

• Positive: the shepherd receives the profit on each additional animal.
• Negative: grazing is slightly degraded for each additional animal.

The cost of overexploiting pasture is an example of a negative externality used as an example of a "commons tragedy". Another modern example of the use of common goods that can be cited is the existing congestion in large cities, so a public good suffers from overuse and loses its value to all. In the latter case, the negative externality generated by free access to the common good causes everyone to lose in mobility.

Hardin (1968) sets out two solutions to the problem of the scarcity of common goods, which are privatization or private property. Since the author was concerned with the way in which the population grows and consequently the availability of common goods is altered more and more people yearn to enjoy the common resources to meet their individual needs and desires, there is pressure on systems and resources, be they natural, social or economic.

Bollier (2008) draws attention to the fact that Hardin (1968) describes a system of open access to resources such as land, which is done without any kind of regulation. To do so, the described land resource presented without limits and without the existence of rules to manage the access to it and its use. In this way, anyone can take what they want, since no one is administering the commons.

On the other hand, thinking about the conscious management of common goods, Ostrom (1986) considers polycentric and multi-actor governance as a way of solving the problems of scarcity arising from the use of common goods. Therefore, for the author the interaction between national, regional and local governance can increase the likelihood of priority common goods conservation.

Ostrom (2000; 2008) argues that local citizens can create organizations with sufficient competence to decide how to manage collective assets, this being done by the aforementioned communal properties. In this way, the state through laws in any scope can incorporate the capacity of local actors in the exploration and use of common goods. Which in turn would lead everyone to a level of awareness about the preservation and future need of these goods. Research based on Ostrom's analysis has shown that human groups do not make unbalanced use of natural resources, as assumed by Hardin (1968).

Therefore, the idea of citizen management of common goods is to establish transparent and effective rules to give access to resources that are common in a shared way. So, with this set of rules one can ensure the proper preservation and use of the resource while protecting the community that shares these assets (Bollier, 2008).

Ostrom's (2000) studies show that as long as the principles and rules of collective ownership set are well-defined, and accepted and respected by all, it is possible to avoid the inconsequential exploitation of common property. In this dynamic, it is worth remembering that common goods are rivals, but they are not exclusive, so self-government makes access easy and maintained to all. Thus, Ostrom (2008) deals with the promotion of self-government, which would be a third way to the aforementioned nationalization and privatization. Moreover, with the use and development of cooperative institutions organized and governed by the users of the common goods themselves, a situation can be promoted that is beneficial to all.

Therefore, to administer the common goods one must attribute or recognize the value of an

externality and its internalization in the economic calculation. On the other hand, it is worth questioning the effectiveness of measuring by means of monetization the externalities arising from the exploitation of common resources. This aspect was greatly explored when discussing Carbon Trade (McHale, Hall, Majumdar& Grimm, 2017; Klein, Siegwolf&Körner, 2016).

In order to facilitate the understanding of the influential elements in the administration of common goods, one must seek to recognize the main aspects that interfere in the categorization and the exercise of ownership of these goods. Initially, one could consider goods as categorized by their aspects of being rival and / or excluding (Table 1). So that after this categorization it is possible to determine the type of property or access to the common goods and the generated externalities of its exploration and use.

Notwithstanding the type of common good, it is often the role of the state to harmonize the conflicting interest of the various agents in the use of these goods. This agent can regulate the economic cannibalization of the externalities that are triggered by society, as this can produce threatening situations that affect everyone in a planetary society and increasingly interconnected (Beck, 2014; Morin, 2013).

In this way, by understanding how to use the common goods, in addition to the costs of their exploitation, an awareness of the costs of use, choice or existence of a good can be spread. Thus, this conceptual framework helps in making decisions about who owns the property and can manage the commons in order to determine present and future responsibilities.

Therefore, by calling the assets available in a society "common", one assumes that it is shared and belongs to the people in general, ie, it does not belong to the government or to a private entity. A resource that is common serves broader purposes than those intended in the market (Bollier, 2008). In determining who will be entitled to ownership of a good, the externalities of its exploitation and use must be taken into account. It is worth emphasizing that the way humanity interacts with nature and transforms the planet will cause it to organize itself or defend itself (Gore, 2013; Morin 2013). In this way, by recognizing the current state of things and making decisions based on the externalities generated thereby, nature could become more resilient.

Contrary to this situation, not taking systemically into account, the future resources state in general and common property in particular, these could lead to deprivation of resources already in the present moment and its shortage in the future. As Sen (2000) points out, development consists in the elimination of deprivations of liberty that limit the choices and opportunities of people to exercise their condition as agent.

3 Conclusion

At the end of this study the issues related to property ownership were addressed, focusing on the management of common pool resources. This subject is addressed by two important positions. On the one hand, Hardin (1968) speaks of the scarcity generated by the shared use of common pool resources. On the other hand, Ostrom (2000; 2008) and Ostrom and Hess (2007) deal with sharing as a way of preserving common pool resources.

In order to deal with this theme, better understandings of the concepts that determine whether the access to the good is rival and / or excluding, as well as the generated externalities of its exploration and use are suggested here. These concepts can assist in the choices that arise when determined whom should be on charge of the common pool resources. Therefore, based on the study of these categorizations in terms of property, function (figure 1), and the kind of externality, a better decision-making process could be reached on the issues of access, and on management regarding preservation and use of common pool resources.

In addition, it is necessary to understand that the consumption of all goods could promote, at some point, positive or negative externalities to other individuals. Awareness of the externality types may help to decide the appropriate ownership and management. On the other hand, just the simple monetization of resources does not solve the problem of negative externalities. Therefore, based on the categorization of the property that has to be exercised and the externalities, it is possible to understand how to manage a good. This situation helps to understand the exercise of control and usufruct of the goods. It should be remembered that this property that is discussed here is related to the ability to determine the use and maintenance of the property.

Thus, taking into account some questions such as: Who should own the property of the common pool resource? What are the negative or positive externalities generated from the exploitation and use of the common good? What is the competence of the agent responsible for administering the common pool

resource? These and other questions can help not only the present state of the common good, but their ability to regenerate and sustain themselves for future generations.

Abstract: Diabetic retinopathy is one of the diseases caused by diabetes mellitus. It can cause leakage of blood vessels in the retina or bleeding, and blurred vision. Early diagnosis of diabetic retinopathy is an important task to prevent blindness. The appearance of exudates is one of the symptoms of diabetic retinopathy. Ophthalmologists use the fundus image of patient to evaluate the exudates. Therefore, it is important to extract the exudates on the fundus image in the diagnosis of diabetic retinopathy. The exudates extraction of the fundus image is a difficult task for ophthalmologists because the fundus image often has poor qualities, such as the boundaries between objects in a less clear and a low contrast and noisy. A good extraction method becomes a necessity in the diagnosis of diabetic retinopathy. Segmentation method is one of method used for exudates extraction. There are many methods of segmentation. Level set method is one of the very well-known methods for image segmentation. It is also widely applied for many applications in image segmentation. The level set method has been successfully used in the medical image segmentation. It has several advantages over the methods of snake, region growing and thresholding. However, when the level set method is applied in the noisy images, it cannot work well. The noise in the images often causes the curve of the level set stopped prematurely in the process of evolution curve, resulting in unsatisfactory results. For this reason, this research uses the level set with fuzzy C-means. The fuzzy C-means is used as preprocessing to handle the noise of image for avoiding from the stopping premature of evolution curve in the level set. Based on these reasons, this paper proposes the hybrid of the fuzzy C-means and level set methods for extracting exudates on fundus image. From the experiment results, it is obtained that the hybrid of the fuzzy C-means and level set methods is able to work better in extracting the exudates on the fundus image than the standard level set method.

Key words: Level set; Edge stopping function; Fuzzy c-Means; Extract; Exudates; Diabetic retinopathy; Fundus image

1 Introduction

Diabetes mellitus is one of the chronic diseases which is caused by deficiency in production of insulin by the pancreas, or by the ineffectiveness insulin production. It is a characterized by the above normal increased blood sugar levels. Indonesia is among the top 10 countries in the diabetes mellitus patients. In 2013, diabetes mellitus patients in in Indonesia is estimated to reach about 8.5 million people with an age range of 20-79 years. This deasease causes many complication deaseses. Vascular complication is one of the complications of diabetes mellitus. Classically the vascular complications of diabetes mellitus are divided into microvascular and macrovascular. The microvascular complications are the diabetes mellitus complication caused by damage to small blood vessels, while the macrovascular complications are caused by damage to larger blood vessels. The most common microvascular complication of diabetes mellitus is diabetic retinopathy.

Currently diabetic retinopathy is the leading cause of blindness in the working age population in the western world (Semeraro et al, 2015). In the early stages, diabetic retinopathy is characterized by a narrowing of blood vessels in the eye which is caused by the accumulation of fluids and fatty material in the retina. It can lead to bleeding in the retinal blood vessel. This condition can lead to blurred vision and be left then it can cause severe vision damage as well as blindness. The risk of diabetic retinopathy can be reduced by early detection, controlling blood sugar, blood pressure, and lipids appropriately (Tarr, 2013).

Ophthalmologists use the retinal images of patients to diagnose diabetic retinopathy. This retinal image is known as the fundus image. The details of fundus images such as small blood vessels, microaneurism, and exudates may be in low contrast. Ophthalmologists usually use the fundus image of patient to evaluate the exudates. The exudates is one of the symtoms of diabetic retinopathy. Therefore, it is important to extract the exudates on the fundus image in the diagnosis of diabetic retinopathy. The exudates extraction of the fundus image is a difficult task for ophthalmologists because the fundus image often has poor qualities, such as the boundaries between objects in a less clear and low contrast and noisy. A good extraction method becomes a necessity in the diagnosis of diabetic retinopathy. Therefore, a method that automatically aided computers will help an ophthalmologist to recognize and

extract the signs of diabetic retinopathy disease.

Segmentation method is one of method which can be used for exudates extraction. The purpose of image segmentation is to divide the image into a separate set of regions with uniform texture attributes, etc. (Dhivya, Anitha, 2014). The image segmentation method can be applied to divide the fundus image area into two parts i.e. the exudate area and the non-exudates area. There are many methods for image segmentation. The image segmentation approach can be divided into four categories: thresholding, edge detection, area extraction and clustering (Yang, Huang, 2007). The thresholding method has several disadvantages, as it relies heavily on peaks and spatial details not considered. While the method of regional extraction is an expensive method in terms of time and memory (Kaur, Kaur, 2014). The edge detection methods are sensitive to noise and produce inaccurate results (Janoriya, Parsai, 2017). Level set method is one of the very well-known methods for image segmentation. It is also widely applied for many applications in image segmentation. The level set method has been successfully used in the medical image segmentation. It has several advantages over the methods of snake, region growing and thresholding. However, when the level set method is applied in the noisy images, it cannot work well. The noise in the images often causes the curve of the level set stopped prematurely in the process of evolution curve, resulting in unsatisfactory results. For this reason, this research uses the level set with fuzzy C-means. The fuzzy C-means is used as preprocessing to handle the noise of image for avoiding from the stopping premature of evolution curve in the level set. For this reason, level set and fuzzy C-means methods for image segmentation will be considered in this paper.

In this paper proposes the hybrid of the fuzzy C-means and level set methods for extracting exudates on fundus image. The results of the exudate extraction of the fundus image will provide the information of diabetic retinopathy sign for ophthalmologists in diagnosing diabetic retinopathy disease.

2 Related Works

This section will describe some theory and the previous research related with this research, such as diabetic retinopathy and fundus image, image segmentation, Perona-Malik difusion filter and level set method.

2.1 Diabetic retinopathy and fundus image

Diabetes mellitus is a chronic disease which is caused by acquired deficiency in production of insulin by the pancreas, or by the ineffectiveness of the insulin produced. It is a characterized by the above normal increased blood sugar levels. Diabetic retinopathy is a micro-vascular complication caused by diabetes that can cause blindness. The first detected abnormality is microaneurism that causes enlargement of retinal capillary enlargement. Broken microaneurism can cause hemorrhage to be seen in Figure 1. (a).

After that it may appear hard exudate as shown in Figure 1. (b). Hard exudate is a leaky lipid formation of weakened blood vessels. Along with the severity of retinopathy disease, the blood vessels may become inhibited causing microinfarct in the retina called soft exudate as shown in Figure 1. (c). The lack of oxygen caused by microinfarct causes the development of new brittle vessels (neovascularization), as shown in Figure 1. (d). This phenomenon can cause a sudden loss of vision. The diagnosis of diabetic retinopathy using fundus image is necessary because the disease is progressive, the example of the fundus image can be seen in Figure 1. (f).

2.2 Segmentation

Information technology is very rapid development in many fields. It has been utilized in medical, such as image processing technology. Image processing technology with artificial intelligence and robotics becomes a promising technology in medical. Anam et. al. proposed a texture analysis and modified level set method for automatic detection of bone boundaries in hand radiographs. The bone boundaries in hand radiograph is needed for segmenting the bone areas and the other areas (Anam et al, 2013). Anam et. al. also proposed a combination of PSO and fuzzy inference for calculation of coronary plaque boundary in IVUS (Intravascular Ultrasound) image. The plaque boundary in IVUS image is neccesary to calculate the plaque area (Anam et al, 2014). Boundary extraction of an image is one of the image segmention method.

Image segmentation is one of the image preprocessing methods in the classification or identification task. Image segmentation is a stage where the image is divided into homogeneous regions based on criteria of specific similarities between the gray level of a pixel with the gray level pixel neighbors. There are many the conventional image segmentation methods to such as gradient-based method (sobel, Prewitt, Canny and Laplacian methods) and template-based methods. Mazid in 2013 proposed a image segmentation method for segmenting the tobacco leaves by using Canny method (Mazid, 2013). Canny method has shortcomings can not produce smooth results. Li et al. proposed a segmentation method in 2005 by using the snake method. This method cannot work well when the image has two or more objects.

The other image segmentation method is level set method introduced by Osher and Sethian (Li et al, 2005). It is one of the very well-known methods and also widely applied for many applications in image segmentation. The level set method has been successfully used in the medical image segmentation. However, if the level set method compared with the conventional image segmentation methods has many advantages. The level set method is very robust and accurate for tracking moving interfaces are complex. The level set method has been widely applied in various fields, in particular for the image segmentation (Anam et al, 2013, Anam et al, 2014).

2.3 Fuzzy C-means algorithm

Clustering is a process of grouping objects based on the objects characteristics, so that all members of each cluster has a certain similarity. The clustering methods can be divided into two categories, i.e. the conventional hard clustering and the fuzzy clustering. The conventional hard clustering method restricts each element of the dataset to exclusively just one cluster. As a result, with this approach the segmentation results are often very crisp, i.e., each pixel of the image belongs to exactly just one class. However, in many real situations, the hard image segmentation is a difficult task because the image often has a limited spatial resolution, overlapping intensities, poor contrast and noise and intensity in homogeneities variation (Zadeh, 1965).

Due to the fuzzy situation, fuzzy set theory was proposed (Bezdek, 1981). It produced the idea of partial membership of belonging described by a membership function. The fuzzy clustering has been widely studied and successfully applied in image segmentation. Among the fuzzy clustering methods,

the fuzzy C-means (FCM) algorithm is the most popular method used in image segmentation (Pham, 2001). It is also one of the best known and the most widely and has been utilized in a wide variety of applications. The FCM algorithm has robust characteristics for ambiguity and can retain much more information than hard segmentation methods (Bezdek et al, 1983).

2.4 Level set method

Level set method was introduced by Osher and Sethian (Osher, Sethian, 1988). It has been widely applied for many applications, especially for detecting the image boundary. The level set method has been successfully used in the medical image segmentation. The contour of level set is represented by the zero level set of a higher dimensional function. It is called a level set function. The contour of level set formulates the motion of the contour based on the evolution of the level set function. The curve evolution of a parametric contour $C(x(s,t),y(s,t))$, is defined by equation (1).

$$\partial C / \partial t = FN \tag{1}$$

t and s denote a set point in time and a curve parameter, respectively. N and F are the inward normal vector to the curve C, and the speed function. The speed function F controls the motion of the contour. The curve evolution of (1) can be converted into a level set formulation by embedding the dynamic contour C as the zero level set of a time dependent level set function $\phi(x, y, t)$. It is assumed that the level set function ϕ gets the positive values outside the zero level contour, and the negative values inside. The inward normal vector can be expressed as equation (2), where ∇

$$N = -\nabla \phi / |\nabla \phi| \tag{2}$$

is a gradient operator.

From equations (1) and (2), the curve evolution in equation (1) is converted to equation (3),

$$\partial \phi / \partial t = F |\nabla \phi| \tag{3}$$

which is referred to as a level set evolution equation. In this paper, we use the level set $\phi(x)$ defined by equation

$$\partial \phi / \partial t = \mu div (d_p (|\nabla \phi|) \nabla \phi)$$
$$+ \lambda \delta_\varepsilon (\phi) div (g \nabla \phi / |\nabla \phi|) + \alpha g \delta_\varepsilon (\phi), \tag{4}$$

(10), where δ_ε is a dirac delta function, div is a divergence operator, and g is a edge stopping function, which is given by

$$g = 1 /(1 + |\nabla (G_\sigma * I)|) \tag{5}$$

equation (11), where G_σ is the Gaussian filter and I is the image to be processed (Li et al, 2010).

3 Proposed Method

This paper proposes a method for extracting exudates on fundus image proposes the hybrid of the fuzzy C-means and level set methods. The data used in this research is the fundus images as shown in Figure 2. The flowchart of the proposed method can be seen in Figure 3. In the flow chart, it can be seen that the first step is to input the fundus image. Furthermore, the image in the RGB (Red, Green, Blue) is converted to the CIE L*a*b format. CIE L * a * b has an element L (Luminance), a (range from green to red) and b (range from blue to yellow). Since the reddish-greenish and yellowish-bluish components of the format CIE L*a*b can differ the exudates area and non exudates area, the components are taken for the input of the fuzzy C-means algorithm. Therefore, the image of the fuzzy C-means result is used to input for the level set method. The final step is to extract the exudates in the fundus image by the level set method.

Input: X (matrix n x m), where n is the number of pixels in the fundus image and m is the number of components image (the reddish-greenish and yellowish-bluish components). c (≥ 2) is the number of cluster. We use c=2 because we want to segment into two areas (the exudates area and non exudates area) and $w = 2$ (weighted)

MaxIt (Maximum iteration)

ξ (Termination Criteria)

Output: V (Cluster Center)

U (Partition Matrix)

Step in Fuzzy C-means Algorithm
1. {Initialization}
t=1; Δ=1.
2. Generate partition matrix, U^0.
3. While ($\Delta \geq \xi$ and t<MaxIt) do
4. Calculate cluster center (V) for each cluster by using Equation (6).

$$v_{ij} = \frac{\sum_{k=1}^{n}(\mu_{ik})^w x_{kj}}{\sum_{k=1}^{n}(\mu_{ik})^w} \qquad (6)$$

5. Calculate distance each data to each cluster center   (d_{ik}) by using Equation (7).

$$d_{ik} = d(x_k, v_i) = \sqrt{\sum_{j=1}^{m}(x_{kj}\text{-}v_{ij})^2}. \qquad (7)$$

6. Update the membership degree for each object on each *cluster* (update partition matrix) by using Equation (8).

$$\mu_{ik} = \left[\sum_{j=1}^{c}\left(\frac{d_{ik}}{d_{jk}}\right)^{1/(w-1)}\right]^{-1}. \qquad (8)$$

7. Calculate objective function by using Equation (9).

$$J_w(U,V;X) = \sum_{k=1}^{n}\sum_{i=1}^{c}(\mu_{ik})^w d_{ik} \qquad (9)$$

with constrained

$$\sum_{i=1}^{c}\mu_{ik} = 1, 1 \leq k \leq n.$$

8. Calculate the difference of partition matrix on the current iteration with the previous iteration, by using Equation (10).

$$\Delta = \left\|U^t\text{-}U^{t\text{-}1}\right\|. \qquad (10)$$

9. $t = t + 1$.

(d)
Figure 2   Fundus Image Used for the Experiment.
(a). Test Image 1st. (b) Test Image 2nd. (c) Test Image 3th. (d) Test Image 4th

4 Results and Discussion

For evaluating the performance of the proposed method, we use the four images of the fundus with the exudates. The various fundus images for evaluating are shown in Figure 2 (a)-(d). The images of Figures 4 (a) - 4(d) show the segmentation results by using the hybrid of the fuzzy C-means and level

set methods and the images of Figures 4 (e) - 4(h) show the segmentation results by using the standard level set methods. Figures 3(a)- 3(d) show that the hybrid of the fuzzy C-means and level set methods successfully exctract between the exudates areas and non exudates areas for almost all images. However, this method fails to differ the exuates areas and non exudates areas in several area as shown in Figure 4 (b), (c), (d). It is caused by the fuzzy C-means algorithm cannot work well to differ the exudates areas and non exudates areas.   Since some exudates areas have similar color intensity with the non exudates areas. To solve this problem, it needs to try other operation to enhance the quality of the fundus image.

5 Conclusion

It can be concluded that the hybrid of the fuzzy C-means and level set methods is able to work better in extracting the exudates on the fundus image than the standard level set method. The hybrid of the fuzzy C-means and level set methods can avoid to the curve of the level set stopped prematurely in the process of evolution for almost all images used.

Research on Business Risk Early Warning Index of Information Technology Industry Based on Logit Regression

Li Yan, Zhang Youtang
School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: 472978018@qq.com, zyt@whut.edu.cn)

Abstract: Making profit is the main purpose of the company. Nevertheless, high profit is always accompanied by high risk. Therefore, excellent risk management capacity is significant for managers. Business risk is one of the major risk that managers face in the operation of the company. In order to help managers, perceive and control business risk,we mainly investigate listed companies of the information technology industry. Then by selecting appropriate monitoring indicators, we adoptthe logit regression to establish a business risk early warning index model.In addition, we design criteria for determining business risk early warning level. The result shows that the business risk early warning index model has good risk forecasting capability and business risk is obviously increasing in the information technology industry from 2015 to 2016.

Key words: Business risk; Monitoring indicator; Early warning index; Logit regression

1 Introduction

In the market economy, business risk is inevitable in the company's production and operation. It mainly results from the fact that actual earnings are different from expected earnings owing to the uncertainty of supply, production, and sales. However, lots of managers only pay attention to huge benefits and ignore business risk. As a result, the company may suffer economic losses and even may go bankrupt. Based on this information, domestic and foreign scholars have been conducting in-depth research on business risk. They make great contributions to business risk early warning and company development.

In foreign countries,it is believed that business risk in the company mainly comes from three aspects: operation process of the company, strategic objectives of the company and the surrounding environment (Korol, 2013; Tapiero, 2015). By analyzing business risk factors, risk early warning models are put forward and applied widely, such as the univariate model and the Z-score model (Fitzpartrick, 1932;Korol, 2013). At the same time, some scholars apply the logit model to analyze business risk,evenperformsome accurate tests (Ohlson, 1980; Hertzel et al., 2011).

In China, according to the actual situation of Chinese companies, scholars do a lot of research on business risk.They subdivide business risk factors into external and internal factors (Chen, 2013; Xu et al., 2018). Grey correlation method and cluster analysis method are used to select business risk monitoring indicators (Yu, 2014). Meanwhile, when building a business risk early warning model, a logit model is considered a good method (Pei et al., 2015; Zhang et al., 2014).

Information technology industry is not only a new strategic industry, but also is a promising industry in the future. Therefore, based on the existing research results and the logit regression method, we take listed companies of the information technology industry as objectand explore how to establish a business risk early warning index model to monitor business risk. Finally, we propose some suggestions to help managers reduce business risk.

2 Data and Methodology

2.1 Sample selection and data preprocessing

In this paper, according to the classification of the listed companies in the CSRC in 2012, we take the information transmission, software, and information technology service industry as the information technology industry, and analyze the relevant data from 2015 to 2016. All empirical data are sourced from CSMAR.

In order to ensure the rationality of data, we select the listed companies on the main board, and remove some listed companies with missing data. At the same time, we use STATA 12.0 software to shrink data to reduce the impact of outliers.

2.2 Business risk monitoring indicators selection based on logit regression

2.2.1 Initial Business Risk Monitoring Indicators Design

Based on the principles of accessibility, comprehensiveness, and pertinence, we design some business risk monitoring indicators from the perspective of development capacity, profitability, and cash

flow, as shown in Table 1.

Table 1   Initial Business Risk Monitoring Indicators

perspective	initial business risk monitoring indicators(x_i)
development capacity	capital accumulation rate(x_1), fixed asset growth rate(x_2), total asset growth rate(x_3), net profit growth rate(x_4), operating profit growth rate(x_5), sustainable growth rate(x_6)
profitability	return on assets(x_7), total asset net profit rate(x_8), current asset net profit rate(x_9),return on equity(x_{10}), operating profit rate(x_{11}), cost profit rate(x_{12})
cash flow	net profit cash ratio (x_{13}), revenue operating cash return ratio (x_{14}), total cash recovery rate(x_{15}), operating index(x_{16}), cash fit ratio(x_{17})

2.2.2 Correlation Test

When the information in indicators overlaps, the reliability of the assessment result is exaggerated. Therefore, we use correlation test to eliminate duplication of business risk monitoring indicators.

By using SPSS19.0 software for correlation test, we find that the correlation of x_1, x_6, x_7, x_8 and x_9 is very high.We eliminate these indicators.Due to limited space, specific empirical results are not listed here.

2.2.3 Business Risk Monitoring Indicators Selection

In a logit regression method, the independent variables do not require strict linear assumption and the dependent variables can be continuous or discrete. Therefore, we usethelogit regression to select business risk monitoring indicators. If the indicator can significantly distinguish whether there is business risk, it should be retained; otherwise, it should be removed.

(1)Normality test

In the paper, we use the Kolmogorov-Smirnov test to check whether business risk monitoring indicators obey normal distribution.All results are shown in Table 2.

Table 2   Normality Test of Business Risk Monitoring Indicators

		x_2	x_3	x_4	x_5	x_{10}	x_{11}	x_{12}	x_{13}	x_{14}	x_{15}	x_{16}	x_{17}
N		101	101	101	101	101	101	101	101	101	101	101	101
Normal Parameters[a,b]	Mean	2.47	0.65	2.22	-0.65	0.07	0.11	0.21	1.62	-2.03	0.04	1.43	-0.43
	Std. Deviation	28.10	1.64	21.16	14.16	0.16	0.24	0.29	14.42	34.98	0.09	17.77	16.69
Most Extreme Differences	Absolute	0.45	0.31	0.35	0.34	0.28	0.24	0.17	0.41	0.44	0.13	0.41	0.40
	Positive	0.45	0.27	0.35	0.27	0.18	0.16	0.17	0.41	0.40	0.08	0.41	0.31
	Negative	-0.45	-0.31	-0.33	-0.34	-0.28	-0.24	-0.17	-0.35	-0.44	-0.13	-0.37	-0.40
Kolmogorov-Smirnov Z		6.81	4.70	5.35	5.12	4.19	3.65	2.63	6.27	6.68	1.96	6.20	6.07
Asymp. Sig. (2-tailed)		0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00

Note: $a$indicates that test distribution is a normal distribution, b indicates that result is from the data

From Table 2, we can see that business risk monitoring indicators do not obey normal distribution.

(2)Difference test

When indicators obey the normal distribution, the difference test is performed by the T-test. When the indicators do not obey normal distribution, the difference test is performed by Mann-Whitney U test.According to the results of Table 2, we use the Mann-Whitney U test. The results are shown in Table 3.

Table 3   Differential Test of Business Risk Monitoring Indicators

	x_2	x_3	x_4	x_5	x_{10}	x_{11}	x_{12}	x_{13}	x_{14}	x_{15}	x_{16}	x_{17}
Mann-Whitney U	351	433	316	195	0	55	1	220	423	270	230	410
Asymp. Sig. (2-tailed)	0.045	0.032	0.743	0.698	0.00	0.00	0.00	0.009	0.254	0.002	0.001	0.054

As can be seen from Table 3, x_4, x_5, x_{14} and x_{17} fail the difference test and they are removed.

(3)Logit Regression

Alogit regression model has the following formula:

$$ln\frac{P}{1-p} = \alpha + \beta_1 * n_1 + \beta_2 * n_2 + ...\beta_j * n_j, \ j=1, \ 2...17 \tag{1}$$

In formula (1), P represents the probability that whether net profit of the listed company is

negative.

When P is equal to 0, it means that the listed company hasn't business risk. When P is equal to 1, it means that the listed company has business risk.We use indicators which successfully pass above test to build the logit regression. The logit regression results are shown in table 4 and table 5.

Table 4   Classification Table^{a}of Logit Regression

			Predicted		
	Observed		Y		Percentage Correct
			0	1	
Step 1	Y	0	94	3	96.9
		1	2	13	86.7
	Overall Percentage				95.5

Note: *an* indicates that the cut value is 0.5

Table 5   Logit Regression Results Between Business Risk Monitoring Indicators

		B	S.E.	Wald	df	Sig.	Exp(B)
	x_2	3.772	2.938	0.542	1	0.747	1.179
	x_3	1.464	9.541	5.231	1	0.000	0.000
	x_4	1.268	1.063	3.287	1	0.014	.231
	x_5	0.200	3.389	0.012	1	0.826	1.221
	x_{10}	11.273	0.207	6.608	1	0.011	0.000
	x_{11}	6.339	2.801	5.621	1	0.000	0.010
Step 1^a	x_{12}	9.576	0.205	2.503	1	0.114	4242.564
	x_{13}	0.178	4.373	1.222	1	0.079	1.195
	x_{14}	0.805	0.767	0.256	1	0.573	2.237
	x_{15}	0.106	1.542	8.211	1	0.000	0.000
	x_{16}	-0.728	0.537	1.923	1	0.683	0.483
	x_{17}	2.405	5.153	7.519	1	0.010	0.009
	Constant	-8.509	4.890	1.324	1	0.030	0.000

Note: *an* indicates that the model is input x_2, x_3,x_4, x_5,x_{10},x_{11},x_{12},x_{13},x_{14},x_{15}, x_{16},x_{17} in step 1

According to the logit regression results, it can be seen that the accuracy rate of business risk prediction is 95.5% and the significance of x_3, x_4, x_{10}, x_{11}, x_{15} and x_{17} is better under the significance level of 0.05. Therefore, these indicators are selected to build a business risk early warning index model and the model can have good risk prediction capability.

3 Business Risk Early Warning Index Model for Listed Companies of Information Technology Industry
3.1 Business risk early warning indicators preparation

Business risk early warning indicators can initially reflect early warning information. We compare business risk monitoring indicators with the early warning threshold to form business risk early warning indicators. The formula for preparing a business risk early warning indicator is as follows:

$$y_i = \frac{x_i - k_i}{|k_i|} \ , i = 3,4,10,11,15,17 \qquad (2)$$

In formula (2),x_i means actual value of a business risk monitoring indicator, y_i means a business risk early warning indicator and k_i means the early warning threshold of a business risk monitoring indicator.

In this paper, we set the early warning threshold as the upper quartile of a business risk monitoring indicator.Ifthebusiness risk monitoring indicator is greater than the upper quartile, the company hasn't business risk. If thebusiness risk monitoring indicator is less than the upper quartile,the company has

business risk.

3.2 Business risk early warning index model

In order to comprehensively reflect business risk, we use the entropy-weighted method to synthesize a business risk early warning index model. The business risk early warning index model formula is as follows:

$$BREWI=y_3*\omega_3+y_4*\omega_4+y_{10}*\omega_{10}+y_{11}*\omega_{11}+y_{15}*\omega_{15}+y_{17}*\omega_{17} \tag{3}$$

In formula (3), $BREWI$ represents a business risk early warning index, $\omega_3, \omega_4, \omega_{10}, \omega_{11}, \omega_{15}$ and ω_{17} represent weights of business risk early warning indicators.

Due to limited space, according to data from listed companies in the information technology industry from 2015 to 2016, we only list the following business risk early warning index results.

Table 6　Business Risk Early Warning Index

code	BREWI		code	BREWI		code	BREWI		code	BREWI	
	2015	2016		2015	2016		2015	2016		2015	2016
000503	0.007	-0.334000835	0.052	-0.157000948		0.014	-0.123002065		0.132	-0.120	
000555	0.113	1.152000839	0.051	0.010000971		0.002	-0.123002072		-0.207	-0.967	
000662	-0.005	-0.014000889	0.068	-0.040000997		0.160	0.033002093		0.029	-0.045	

3.3 Business risk early warning index analysis

In order to analyze business risk of listed companies in the information technology industry, we use the upper quartile, the median, and the lower quartile of business risk early warning indexes as business risk level criteria. Simultaneously, the $\mu1$ represents the upper quartile, the $\mu2$ represents the median, and the $\mu3$ represents the lower quartile. When $BREWI\in(\mu3,\max BREWI)$, it means that the listed company has no business risk; when $BREWI\in(\mu2,\mu3]$, it means that the listed company is in a light business risk level; when $BREWI\in(\mu1,\mu2)$, it means that the listed company is in a medium business risk level; when $BREWI\in[\min BREWI,\mu1]$, it means that the listed company is in a heavy business risk level.

By measuring $\mu1$, $\mu2$ and $\mu3$ of business risk early warning indexes in 2015 and 2016, business risk early warning levels of listed companies in information technology industry are reflected in the following figures. The red line represents $\mu1$, the orange line represents $\mu2$ and the yellow line represents $\mu3$.
Figure 1　Business Risk Early Warning Level in 2015
Figure 2　Business Risk Early Warning Level in 2016

We can see that business risk of listed companies in information technology industry has deteriorated and the gap between companies' business ability has increased. Because in 2016, some policies were introduced to encourage development of the information technology industry. If managers could seize the opportunity to profit and control risk, business risk would decrease, or business risk would increase.

4 Conclusion

In this paper, we build a business risk early warning index model through the logit regressionand analyze business risk of listed companies in the information technology industry from 2015 to 2016. Unfortunately, we find that business risk is increasing obviously during this time. In order to reduce business risk, we propose the following suggestions for managers. First, managers should improve costs and expenses of management. Second, managers need make full use of various assets, including idle assets. Third, managers had better strengthen the competitiveness of products in the market and avoid the bad debts of accounts receivable.

Notably, internal factors are dominating factors that lead to business risk of the company, which are key points we discuss in this paper. In furtherresearch, we will try to combine internal and external factors to build a more scientific and comprehensive index model.

Analysis of Multi-agent Game of Social Co-governance in Food Safety Risks

Ma Ying, Kang Ping, Jin Li
School of Management, Wuhan Universityof Technology, Wuhan, P.R.China, 430070
(E-mail: mying331@163.com, 462643081@qq.com, kpkangping@126.com)

Abstract: This paper uses the game theory method to analyze the interests of multi-agents in the social governance of food safety risk. According to domestic and foreign experience, when the risk of food safety develops well, all parties involved in the game can obtain more benefits. This also shows that social co-governance has the necessary conditions for the cooperation of various game players. Due to changes in government functions, diversified food safety management has become a trend. The cooperation game of each subject can realize a kind of benefit distribution scheme that each subject is satisfied with, which is also the main direction of this article.
Key words: Food safety risk; Social co-governance; Multiple entities; Game

1 Introduction

Compared with the monopolistic governance that is more monopolized, the first issue that must be considered in the process of multi-governance of food safety risks is the conflicts, choices, and even conflicts of interest among various stakeholders. According to the related theories of game theory, stakeholders will maintain their own interests, which makes the subject unable to achieve complete rational behavior. Corresponding to this, several parties involved in social co-governance, including government, platform organizations, consumers, and food companies, have played different roles in society. They have different starting points, competing for different interests, and have no resources in society. On average, there are differences in the decisions to be made based on self-interest. Therefore, the process of building food safety risk and social co-governance is actually a process of coordinating the relations between several parties to achieve a balanced process. In this dynamic balance, the society is maintained. Stable.

As the main parties involved in the joint governance of food safety risks, the government, platform organizations, consumers, and food companies represent different stakeholders. However, while the interests of all parties involved in the game, there are uncertain interest objectives and conflicts of interest in all parties of the game. From the perspective of the entire game process, if a single static game is used for years, each player has two strategies of cooperation (C) or non-cooperation (N) (Bailey A P, 2014). However, in real life, the governance of food safety risks is greatly affected by the government's macro-control and the executive power of companies (DengGanghong, 2015). Consumers are playing more of an outsider's role and can't make rational and free decisions in the game. Therefore, this study selected a cooperative game model for analysis.

2 Cooperative Game Model Analysis

There are several differences between cooperative games and non-cooperative games. First, the premise of the cooperative game is that the parties involved in the game have common interests, that is, the cooperation game must be a "positive-sum game." Second, all parties involved in the game must have the necessary information exchange, and all parties should eliminate the obstacles of information asymmetry between the game parties through information exchange (Kong D, 2012). The parties involved in the game have a clear and stable expectation of the cooperation results, and can have an accurate judgment of future trends. Third, all parties involved in the game must be founded on the basis of equality, voluntariness and mutual benefit. All parties in the game can share profits in cooperation, at least their own interests will not be compromised. Fourth, the cooperation game must include a binding contract, and this contract has credibility, and any party who violates the contract will be punished.

Since all parties involved in social co-governance have their own interests and needs, if all parties only consider themselves and ignore other parties, they cannot achieve their own interests.

According to the concept of game theory, the ultimate interests of one party not only depend on their own decisions, but also have a great relationship with other parties involved in the game. The Nash equilibrium indicates that at least one such result exists. In the case of complete disclosure of information, the party that participates in the game has a clear expectation of the strategies of other parties can make any party to do any strategy cannot improve the results. Prior to the analysis, it is assumed that all parties involved in the game are equal, and one party can issue an irreversible threat to the other party and achieve a cooperative game through a contract or a specific strategy.

According to the above analysis, it can be known that the main body of cooperative governance in food security risk social co-governance is based on the cooperation game, that is, parties participating in the game have common goals (Wishing, 2015). As long as the main players participating in the cooperative game receive no less than the non-cooperative benefits, the parties constrain each other's actions in the form of a contract, thereby obtaining a satisfactory distribution plan for each subject.

3 Establishment of Game Model of Social Security for Food Safety Risks

There are two game modes in game theory, zero-sum game and non-zero-sum game. The so-called zero-sum game refers to the fact that the two sides of the game are confrontational in nature and the interests of one party are based on the losses of the other party. The non-zero-sum game refers to the fact that the relationship between the two sides of the game has a consistency of interests, and is not completely confrontation and conflict. Certain behaviors on both sides of the game can benefit both parties. The social co-governance of China's food safety risks also has the characteristics of such interest consistency. According to foreign experience, parties involved in social co-governance can achieve common profits(Wu Yan, 2012). This also shows that there is a common goal for all parties involved in social co-governance, which is the basis for the cooperation game.

3.1 Participants

The participant in game theory refers to the decision-making body involved in the game. His goal is to maximize his own payment level by choosing behaviors. This article mainly selects several major stakeholders involved in the food safety social co-governance to conduct analysis and modeling, namely government, platform organizations, consumers and food companies (Wang Chen, 2007).

Government (G). The government is the communicator of social governance. The government manages the organizational groups and consumers in the society through the enormous resources and release policies in hand (Xie Min, 2007).

Platform Organization (P). The regulation of food as a regulatory power can also be used as a supplementary information disclosure mechanism to guide the healthy development of the food market.

Consumer (C). Consumers are the triggers of food safety, and they are also the most important stakeholders in governance. Food safety accidents are generally initiated by consumers. As consumers pay more attention to their own interests, they have played an increasingly important role in social governance. The more important role.

Food Business (E). Food companies are responsible for food safety, including food production companies and other companies in the food supply chain. Under the food safety supervision system, food companies are relatives of administrative management and are in the position of being controlled (Yan Yan, 2008).

3.2 Model assumptions

It is assumed that all parties participating in the food safety social co-government will invest their own resources, and at the same time, all parties will jointly assume various risks in food safety. The parties involved in social co-governance all have their own expected benefits, and they distribute their benefits in food safety through their own negotiating power and the degree of fear of negotiation. It is assumed that all parties involved in social co-governance have a common goal, that is, the overall benefits of food safety, which is also the basis for all parties to participate in cooperation. Assuming that the cost of participating in social co-governance is V, the negotiation power of each subject participating in the cooperative game is ui (iG,P,C,E), and the degree of

concern about the negotiation is fi (iG,P,C,E) when negotiating The revenue received by the parties at the time of the breakdown is Xi (iG,P,C,E), and the gains obtained by the parties based on the negotiations are u(Xi) (iG,P,C,E), and the gains the parties receive when the negotiation breaks down For Vi (iG,P,C,E). Fi is determined by the individual functions involved in the game, which is negated by the negotiating party i. Vi is the lowest level of the overall income distribution for the subject i participating in the game. Since the model established this time is the result of multiple negotiations of the parties involved in the game, Vi can also be seen as the gain of subject i after the last negotiation. Among them, u(Xi)=Xi-Vi, which shows that u(Xi) is the net income of subject i in the cooperative game (Zhao Dawei, 2017).

3.3 Model establishment

According to the principle of Nash equilibrium, the parties involved in the cooperative game must have an equilibrium strategy when making decisions. When there is an allocation strategy in the global distribution set E(V) that is not super-optimized by any other allocation, it is called Pareto optimal. The key question whether the cooperative game solution exists is whether it can form a value of common interest, which is called the "negotiation welfare function". Unlike non-cooperative games, parties involved in cooperative games not only consider the maximization of their own revenue, but must also consider the existence of constraints. These constraints can be expressed through Nash's axioms. The "negotiation welfare coefficient" in cooperative games is the common interest of different subjects, and reflects the concept of joint recognition by all parties involved in cooperative games. The parties involved in the cooperative game negotiate under the conditions of "negotiation welfare coefficient" and obtain their own benefits through negotiation. The concept of Nash equilibrium is a direct reflection of individual rationality, and Nash's negotiating solution is a reflection of the collective rationality in the distribution of interests among game parties. Since Nash's negotiating solution is a Pareto optimal solution, the result obtained through negotiation is a direct reflection of collective rationality. There is a necessary condition for Nash's negotiating solution: Each subject participating in the cooperation is premised on self-interest (Zhou Qingjie, 2010). Based on the above analysis, we can see that the food safety social co-governance model satisfies the following conditions: ① individual rationality and collective rationality of each subject participating in the cooperative game; ②the core of the cooperative game is a non-empty set; ③super-additive; ④ independence independent choice, that is, to satisfy the existence of the model solution.

The gains from the negotiation of the social co-government parties are greater than the gains from the negotiated break-up, that is,$X_i \geq Y_i > 0$ is satisfied. On the basis of Nash's axioms, Nash's theorem has been generalized by introducing the concept of negotiating power γ_i and the degree of concern about the breakdown of the negotiation f_i. Which meets:

$$\sum_{1-C}^{N} \gamma_i = 1$$
$$\frac{\partial X_i}{\partial \gamma_i} > 0$$
$$\lim_{\gamma_i \to 0} X_i = V_i = 0$$
$$\lim_{\gamma_i \to 1} X_i = X$$

The parties involved in the game must also accept the constraints under the premise of satisfying the above formula:

$$\sum_{i=G}^{N} X_i = X$$

Under this constraint, choose the maximization of self-interest. That is, game player i chooses the largest one of the objective functions $\prod_{i=G}^{N} u_i \cdot \gamma_i$. A new objective function, $\prod_{i=G}^{N} u_i \cdot \ln \gamma_i$, is obtained by applying a regular transformation to the objective function and taking the natural logarithm. The new objective function and the constraint condition together construct a Lagrangian function:

$$L = \sum_{i=G}^{N} u_i \cdot \ln \gamma_i + \lambda \left(\sum_{i=G}^{N} X_i - X \right)$$

Among them, λ is a variable.. Take a first-order condition to get:

$$\gamma_i \frac{u_j}{u_i} - \lambda = 0$$

$$\gamma_i \frac{u_j}{u_i} = \gamma_j \frac{u_i}{u_j} \ (i \neq j)$$

3.4 Analysis of cooperative game model results

According to, $f_i = \frac{u_i(X_i)}{u_i'(X_i)}$, the formula of the degree of fear of the breakdown of the negotiations by the game subject, X_i is related to it. Therefore, the degree of concern of the subject i participating in the game is constantly changing along with the income X_i obtained. Assuming that $u_i(X_i)$ is a concave function, for any $u_i(X_i) > 0$, we get:

$$\frac{\partial f_i}{\partial X_i} = \frac{[u_i'(X_i)]^2 - u_i(X_i)u_i''(X_i)}{[u_i'(X_i)]^2} > 0$$

According to the above formula, we can know that the degree of concern of each stakeholder involved in the cooperation game is positively related to the benefits.

For the food safety social co-governance model that we have established, we can draw the conclusion that: 1. The degree of concern of the various stakeholders involved in social co-governance on the negotiation is directly proportional to their own gains in the negotiations.

For further explanation, assume that only two subjects, i and j, play the game. The negotiating power of the two subjects is γ_1 and γ_2 respectively ($1 > \gamma_1 . \gamma_2 > 0$, $\gamma_1 + \gamma_2 = 1$). Under the conditions of meeting the above axioms, both parties involved in the game negotiate the right of social co-governance. If i derives the gain from the negotiation as X_i, then the gain of the other subject y from the negotiation is $V-X_i$. Then you can get the following formula:

$$\frac{X_1}{V - X_1} = \theta \frac{\gamma_1}{\gamma_2} \ (\theta > 0)$$

Assuming $\frac{\gamma_1}{\gamma_2}$=y, we can simplify the above companies:

$$X_1 = \frac{\theta V_y}{1 + \theta_y}$$

By deriving the above equation, we can get:

$$\frac{\partial X_{1i}}{\partial y} = \frac{V\theta}{(1 - \theta y)^2} > 0$$

From this we can conclude that the net income of one side of the game is proportional to its own negotiation power.

According to the social co-governance model, we can draw the conclusion 2: The participants who participate in social co-governance have stronger negotiating power and can get more net income in the final income.

Taking into account the extent of both parties' concerns about the breakdown of the negotiations, they will reach a mutual compromise solution. After many negotiations reached a critical point, the utility boundary. According to the popularized Nash negotiation model, the participants involved in the game will negotiate to maximize the following:

$$U = \max \cup_G \gamma G \cup_I \gamma I \cup_C \gamma C$$

According to the formula of the degree of fear of the breakdown of the negotiations by the game player, $f_i = \frac{u_i(x_i)}{u_j(x_j)}$, and satisfying at the optimal solution:

$$\frac{f_i}{\gamma_i} = \frac{f_j}{\gamma_j}, \ \ i,j = G, P, C, E (i \neq j)$$

Replace f_i with the following:

$$\frac{u_i(X_i)}{u_j(X_j)} = \frac{\gamma_i}{\gamma_j} \times \frac{u_i'(X_i)}{u_j'(X_j)}$$

From this we can draw the conclusion that the benefits of each subject participating in social co-governance will depend on its own negotiating power and the ratio of profit evaluation at the optimal solution.

Based on the above analysis, it can be known that if the bargaining power of each subject

participating in the game is determined, the degree of realization of each subject at the solution point is determined by the specific characteristics of each party. If one of the players participating in the game is too negotiating power, there will not be much gain.

The model of social co-governance is the interest distribution model of each subject in the joint governance of food safety risks, and the way to realize the distribution of benefits is through many negotiations. In other words, the benefit distribution model of social co-governance is endogenous and is determined by the bargaining power and utility function of each subject participating in the cooperative game.

This concludes that in order to maximize the benefits of the various players in the cooperative game, the main body needs to increase its own negotiation power. For the model of social co-governance, platform organizations and consumers need to increase their own negotiating power to obtain more benefits, that is, they need more investment in food safety risk management.

4 Conclusion

Based on the above analysis, we can draw the following conclusion: The precondition for the formation of a cooperative game in social co-governance is the complementarity between the various players participating in the game. Participating parties reach a final benefit distribution agreement through consultation and negotiation, and restrict the behavior of all parties through a binding contract. Food safety is related to the interests of all parties. The benefits of the cooperation of the subjects who satisfy the cooperative game conditions are not less than the benefits of individual individuals when they are not cooperative. At the same time, the cooperation game is based on the conditions of fairness. Any subject's destruction of the cooperation game will lead to the decline of its own interests. Therefore, all parties involved in the cooperative game need to cooperate sincerely to achieve greater benefits.

In addition, there are different interests in social governance, including government, platform organizations and consumers, and food companies. However, although there are conflicts of interest distribution between these subjects, at least there is an allocating scheme acceptable to all subjects so that each subject can get no less than uncooperative profits through cooperation. In general, the greater the benefits from cooperation, the more economically compensated the less profitable party, and the amount of compensation is determined. The compensation mechanism can promote the enthusiasm of all parties involved in the cooperation, and it can also form a positive guiding role, which is conducive to the healthy development of food safety risks.

Finally, the distribution of the benefits of the socially coordinated stakeholders is related to their bargaining power. Because of the influence of various factors such as history and policies, the parties involved in the game are different in their negotiating power. In order to achieve the goal of diversified management, it is necessary to support the disadvantaged players (consumers, platform organizations, etc.) in the game. The realization of such a process requires the active participation of consumers and platform organizations, and the government and the company's strong support to realize it, so as to truly manage social diversity and maximize the interests of all parties.

Impact of Economic Value Addition of Economic Innovation on US Equity Risk Premium

Chamil W Senarathne, Wei Jianguo
School of Economics, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: chamil@whut.edu.cn, weijg@whut.edu.cn)

Abstract: This paper examines the impact of EVA of economic innovation of OECD countries and USA on US equity risk premium using Ordinary Least Square (OLS) regression and Vector Autoregression (VAR) framework. The results show that the EVA of OECD and USA negatively impacts US equity risk premium. This implies that, when the economic value addition of innovation decreases, the equity holders increase the risk premium required for possible unsuccessful innovations (risk of innovation) undertaken at the expense of owners' capital. Equity holders are more concerned about the process of innovation than the value of innovation. As such, the economies of innovation of emerging countries (including USA) such as OECD have become an important source of information for US equity market. It also reveals that the US equity market is more sensitive to cross-market information transmission on economic innovation. All lag coefficients of VAR regression are statistically insignificant and the residual diagnostic does provide successful results. VAR regression results provide some evidence for the existence of efficient conditions in the US equity market.
Key words: Economic innovation; Economic value added; Market efficiency; Impulse response; Equity risk premium

1 Introduction

One of the concluding remarks of the classical book of Schumpeter, (1912) is that the innovation itself is risky. The principle financial objective of capital providers is to maximize their wealth. The capital providers therefore expect an additional premium for approving their agents (i.e. managers of owners' capital or funds) for taking risk in the course of managing owners' capital employed. The choice between life and death of a firm is rest with the managers of owners' capital and is determined by their ability to be innovative (See e.g. Audretsch 1995; Baumol, 2002, p. 1; Cefis and Marsili, 2005). Benefits of innovation on the other hand do not only accrue to the firms involved in the innovation activities but other firms, society or even related industries (See e.g. Porter and Kramer, 2011). Therefore, the transmission of information on firms' innovation between markets is inevitable at this incredible pace of current advances in information technology (information transmission between equity exchanges has been extensively discussed by Eun and Shim, (1989), Koutmos and Booth, (1995), Bottazzi and Peri, (2003), Amanjot and Manjit, (2016), Maderitsch, (2015), Bhuyan*et al*, (2016), Thenmozhi, and Chand, (2016), Al Rahahleh and Bhatti, (2017), Al Rahahleh*et al*, (2017)).

Spending on research and development does not always guarantee a successful innovation (Link and Scott 2011). The success of innovation depends on how efficient and effective the innovation process is handled and the resources are used. The monetary benefits of innovation can be determined by, for example, comparing the difference between value of patent (innovation output) and the research and development expenses (innovation input). This however disregards the cost of capital tied up in the innovation process (i.e. funds deployed on research and development activities leading to innovation) of the firm. As such, one would charge the cost of capital employed on the amount invested in research and development to arrive at the residual benefits accruing to the firm on research and development activities (e.g. Economic Value Added (EVA)). If the owners (capital providers) approve their managers to engage in innovation activities at the expense of owners' capital, of course, they expect an additional premium for accepting such a risk. Nanda and Rhodes-Kropf, (2016) examine the impact of financing risk on the type of new ventures that engaged in innovation and find that the financing risk impacts innovative ventures with the greatest real option value at the financing stage. EVA, in fact, measures the economic value addition of innovation attributable to an economy (See Jakub *et al* 2015 for similar arguments).

The objective of this paper is to examine the impact of economic value addition of economic innovation of OECD countries and USA on US equity risk premium using Ordinary Least Square (OLS) regression and Vector Autoregressive (VAR) framework. The standard EVA computation method will be used to estimate the time varying residual benefits accruing to firms at market level. The section two introduces the methodology and the regression equations under OLS and VAR frameworks. Section

three briefly outlines the data set used and the sources of data. Some descriptive statistics are also provided. Section four reports the findings and section five provides concluding remarks.

2 Methodological Framework

Assume that firm j in the market with k number of fully equity financed firms raise finance where the whole sum of money so raised is entirely devoted for the purpose of innovation[1]. As such, output of each firm is clearly a function of innovation. Each firm classifies research and development expenditure (R&D) (let it denote D) under intangible assets (at cost) and recognizes the difference between value of corresponding patents (A) and the cost of R&D as profit and loss for the period. In particular, assume that the books of accounts are clearly divisible for each line item so that the firms can forthwith identify the revenue and capital expenditure for innovation. The financial results of innovation process (F) of firm j at time t could then be written as $F_{jt} = A_{jt} - D_{jt}$ and the aggregate financial results (taxes are ignored) of all firms (on innovation activities) in this fictitious economy (c) would then become, $F_{ct} = \left(\sum_{j=1}^{k} A_{jt} - \sum_{j=1}^{k} D_{jt} \right)$. Each firm has a stated capital (capital invested) of which D_{jt} is applicable to capital raised on innovation, so that all firms have $D_{ct} = \sum_{j=1}^{k} D_{jt}$ amount of capital invested in this section of business operation. Since these firms are not necessarily be listed in the stock exchange, an ascertained cost of equity is not readily available. As these firms are engaged in innovation which is risky, the owners (or managers) of each firm consider equity market return as the most suitable opportunity cost of capital (See carefully Jakub et al 2015). The EVA of economic innovation at time t can therefore be written as;

$$EVA_{ct} = F_{ct} - \left(R_{mt} * \sum_{j=1}^{k} D_{ct} \right) \tag{1}$$

Equity market risk premium (EMRP) of this economy could be computed as simple as $R_{mt} - R_{ft}$ where R_{mt} is the return on market portfolio at time t and R_{ft} is the risk-free rate of the economy which is proxied by one-year US treasury bill rate.

The relationship between EMRP and EVA of economic innovation could be examined by the following equations for both OECD and USA.

$$R_{mt} - R_{ft} = \theta + \beta_1 EVA(USA)_{ct} + \beta_2 GDPGR(USA)_{ct} + \varepsilon_t \tag{2}$$

$$R_{mt} - R_{ft} = \Omega + \beta_3 EVA(OECD)_{ct} + \beta_4 GDPGR(OECD)_{ct} + u_t \tag{3}$$

Where θ and Ω are the intercept terms. EVA and $GDPGR$ denote the economic value addition and gross domestic production growth rate of USA and OECD[2]. ε_t and u_t are the error terms of the regressions which are assumed to be well behaved. $GDPGR$ is included in the sense of Vassalou (2003) as a control variable. Any impulse response of the dynamic systems of equations forming the above relationship can be examined by the following Vector Autoregressive equations for OECD and USA.

The following systems of equations examine the impulse response of equity risk premium and EVA of USA and OCED countries.

US Equation

$$R_{mt} - R_{ft} = \omega + \sum_{i=1}^{p} \psi(R_{mt-i} - R_{ft-i}) + \sum_{i=1}^{p} \varpi EVA(USA)_{ct-i} + \epsilon_t \tag{4}$$

$$EVA(USA)_{ct} = \sigma + \sum_{i=1}^{p} \xi EVA(USA)_{ct-i} + \sum_{i=1}^{p} \varkappa (R_{mt-i} - R_{ft-i}) + o_t \tag{5}$$

OCED Equation

$$R_{mt} - R_{ft} = \mu + \sum_{i=1}^{p} \eta(R_{mt-i} - R_{ft-i}) + \sum_{i=1}^{p} \zeta EVA(OECD)_{ct-i} + v_t \tag{6}$$

$$EVA(OECD)_{ct} = \alpha + \sum_{i=1}^{p} \pi EVA(OECD)_{ct-i} + \sum_{i=1}^{p} \gamma(R_{mt-i} - R_{ft-i}) + z_t \tag{7}$$

Where ω, σ, μ and α are the constants of equations (4), (5), (6) and (7) and the rest of the coefficients are assigned to capture the evolution to either variable with a 1σ shock to each variable at a time.

---

[1] Excess return is therefore justified by innovation.
[2] Average in case of OCED.

3 Data

Equity index data are obtained from the New York Stock Exchange[1]. 1-year treasury bill market rates are obtained from U.S. Department of the Treasury[2]. Gross domestic spending on R&D[3] and Patent data are obtained from OECD Data Library[4]. Gross domestic production growth rates are obtained from the World Bank national accounts data, and OECD National Accounts data files available on World Bank Group data library webpage[5]. Initial sampling period of Patent covers data from 1985 to 2015 and the known data from 1985 to 2015 showed a trend of rising volatility. Based on the available data, the average growth rate is calculated first, and then the data for the period 1980-1984 are derived based on the moving average growth rate. Same basis is used to compute the R&D expenditure for the year 1980. Equity index data are not subject to any computations. Some descriptive statistics are given in Table 1.

Table 1   Statistical Properties

Variable	Mean	Median	Max.	Min.	JB	ADF	LM
R_m	0.072	0.103	0.272	-0.526	35.779*	-6.36*	NA
R_f	0.047	0.049	0.131	0.001	1.363	-1.417	NA
$R_m - R_f$	0.026	0.043	0.244	-0.542	22.992*	-6.745*	0.8911
$GDPGR(USA)_c$	2.649	2.776	7.259	-2.775	5.186	-4.229	NA
$GDPGR(OECD)_c$	3.470	3.398	6.460	0.103	0.041	-3.323	NA
$EVA(USA)_c$	-307026	-293444	-130859	-505763	1.982	0.856	NA
$EVA(OECD)_c$	-730692	-702591.2	-305336.2	-1251974	1.994	1.092	NA

Note:

1. JB - Jarque–Bera test statistic for normality. Under null hypothesis for normality, critical value of χ2 (2) distribution at 5% significance level is 5.99.

2. ADF- Augmented Dickey–Fuller test statistic for stationarity of data for maximum 8 lags. Under null hypothesis for data having unit roots, the critical value at 5% significance level is -2.95 (MacKinnon (1996) one-sided p-values).

3. LM is the ARCH LM test statistic for number of observations multiplied by the R-squared value for 3 lags. Under null hypothesis, critical value of χ2 (3) distribution at 5% significance level is 7.815 (OLS equation, $R_{mt} - R_{ft} = c + \varepsilon_t$)

4. *Statistically significant at 5%, assuming conditional normality and **Statistically significant at 10%.

As per the results outlined in Table 1, US stock market return exhibits an unconditional nonnormal distribution as null hypothesis of JB test is clearly rejected. Data has also shown to have unit roots (non-stationarity) as ADF test statistic is well below the critical value of -2.87. However, US TB rates obey the disciplines of a well-behaved regression variable such as normality and stationarity. The unconditional distribution of US risk premium is however non-stationary and nonnormal. Serial correlation in risk premium is not observed as null hypothesis of ARCH-LM test is accepted. *GDPGR* for USA and OECD are nonstationary (marginally exceeds the critical value) but the distributions are clearly normal. Surprisingly, both $EVA(USA)_c$ and $EVA(OECD)_c$ variables are stationary and normally distributed as appropriate candidates for regression. The negative values of EVA indicate the risk of innovation as sunk cost of unsuccessful R&D.

4 Results

The regression results of equations (2) and (3) show that there is a significant negative relationship between EVA of economic innovation of OECD countries and USA, and US equity risk premium. This implies that, when the economic value addition of innovation decreases, the equity holders increase the risk premium required for possible unsuccessful innovations undertaken at the expense of owners' capital. It is shown that the EVA of OECD countries is negatively (significantly) related to US equity risk primum, which indicates that equity investors of USA are more vigilant about the sources of information pertaining to innovations of emerging economies. It also implies that US equity market is

---

more sensitive to cross-market information transmission on economic innovation. Moreover, the coefficients of $GDPGR$ in both USA and OECD equations become statistically insignificant, confirming that the news related to future GDP growth as a risk factor in equity returns are reflected in the EVA of economic innovation.

Table 2   OLS Regression Results

Equation	(2)				(3)			
	β_1	t-stat	β_2	t-stat	β_3	t-stat	β_4	t-stat
Coefficient (NW)	-8.78E-07*	-3.221	0.018	1.297	-3.42E-07*	-3.100	-0.013	-0.905

Note:
1. NW stands for Newey and West (1987) procedures for the estimate of regression coefficients on the robust standard errors for consistent heteroskedasticity and autocorrelation.
2. *Statistically significant at 5% significance level assuming conditional normality.

As outlined in Table 4, the results of VAR show that none of the coefficients in the systems of equations are statistically significant as t-statistic is below 2 for all lag coefficients of either equation. The structure of VAR has however been unable to explain the underlying process as expected. VAR stability condition test shows that the residuals of two equations are nonstationary as 12 roots fall outside the unit circle. It is usual to observe some insignificant coefficients in VAR type of regressions. In such case, researchers usually carryout residual diagnostics to ensure the appropriateness of the VAR specification. Except for stability condition test, the residual diagnostic tests are clearly satisfactory. Errors are not serially correlated as null hypothesis of no serial correlation under residual serial correlation LM test is accepted. The results of Jarque–Bera joint test for normaily show that the residuals are multivariate normal. Null hypothesis of no cointegrating equations is accepted as the trace statistic of Johansen cointegration rank test is below the critical value (5%). As such, the initial conditions of the systems do provide a fundamental solution to the problem and the relationship is limited to a significant linier (contemporaneous) relationship between equity risk premium and EVA of economic innovation.

Notes
1. Asymptotic t-statistics appear in parenthesis.
2. VAR-LM is the VAR Residual Serial Correlation LM Test. Null Hypothesis: no serial correlation at lag order h. Probabilities from chi-square with 4 df.

3. VAR is the stability condition test for roots of characteristic polynomial, under null hypothesis for all roots fall outside the unit circle. Number of roots outside the unit circle is reported.

4. VAR-N is the VAR residual normality test (Orthogonalization: Cholesky -Lutkepohl). Jarque–Bera (joint) test statistic is reported. The null hypothesis: Residuals are multivariate normal.

5. JCT is the Johansen Cointegration Rank Test for 1 to 2 lag intervals. Null hypothesis: no cointegrating equations.Trace Statistics for 'None' and 'At Most 1' are reported, respectively.

6. *Statistically significant at 5% significance level, assuming conditional normality of errors. ** Statistically significant at 10%.

5 Conclusion

The economics of innovation suggest that the survival of a firm depends on its ability to be innovative in the business. Innovation however exposes firms to risk as the success of innovation is uncertain. Equity holders of these firms therefore demand an additional compensation for holding (or investing) securities as the innovation impacts the shareholder risk. As such, the economies of innovation cannot be interpreted without reference to the expectations of capital providers, (if Schumpeter, 1912) is respectfully acknowledged. The EVA of economic innovation provides a prudent assessment of residual benefits of economic innovation that takes into account the opportunity cost of capital invested as well as economic excess of innovation.

The regression results as in (2) and (3) show that the US equity risk premium is negatively related to EVA of economic innovation of USA and OECD countries. When the EVA of economic innovation is reduced, the equity holders increase the risk premium as a compensation for the risk of an unsuccessful innovation (innovation that does not meet the excepted outcome). Economies of innovation of emerging countries such as OECD have become an important source of information for US equity market (i.e. investors of the market). Equity holders are more concerned about the process of innovation (i.e. how efficient and effective the innovation process is handled, in order to provide the required return on firms' investment in innovation) rather than the value of innovation (i.e. value of patents).

VAR regression results do suggest that the shocks to residuals of systems of equations do not persists over time. None of the coefficients of lagged variables have become statistically significant and the residual diagnostics ensure the specification of VAR. If financial markets are efficient, there should be no correlation between current price changes (or increments) and lagged price changes or lagged economic variables of the same country or other countries (e.g. innovation, economic growth). Instead, the underlying variables should reflect the relevant information simultaneously (See especially Hsu *et al* 2007). The findings of VAR regression therefore provide some evidence for the existence of efficiency in the US equity market.

Abstract: The private sector of Ghana faces many problems with respect to raising capital for their operations; this is largely due to government relying heavily on the local credit market for funds for developmental projects. This study uses exponential smoothing method (ESM) in EViews to build a single sample model to forecast future domestic credit to private sector (DCPS) values in Ghana. Secondary annual data on DCPS spanning the period from 1982 to 2016 is used. The findings show that an exponential smoothing model with multiplicative error, additive trend and no seasonality fits the data best. The model had very small residual measures, which demonstrates a good model for forecasting. The estimated model is used to forecast the DCPS values for Ghana from the year 2017 to 2020. The results of this study will help private business people plan for the future. The results will also help policy makers to make informed decisions and formulate policies to improve the DCPS figures, since the private sector is the engine of growth, and crowding out would not be in the best interest of the government and the nation as a whole.
Key words: Domestic credit forecast; Regression forecasting; Ghana private sector; Bank credit

1 Introduction

The private sector is the focus for the current government of Ghana who took office after winning the December 2016 general elections. Most of the promises made to the electorates to compel them to vote massively in favor of this government are private sector driven. The big ones that will resonate in the ears of the electorates for a long time, and may be the yardstick to measure the performance of this government after the four years tenure are the "one village, one dam" and "one district, one factory". Therefore, for this government to remain appealing to the voters in the next election, it has no choice, but to strengthen the private sector to help in fulfilling their promises.

According to　(Hauner, 2008), there is a huge negative impact of domestic credit to government on bank deepening in developing countries, but no effect in advanced economies. The study also found that, though, credit to government increases profitability, it decreases efficiency drastically in developing countries, meanwhile, in advanced economies, there is no significant impact on profitability, but there is a positive impact on efficiency. (Hauner, 2008) concluded that, though the practice shows no effect on developed economies, it has long-term negative repercussions on financial development in developing countries and might eventually cause crowding out of the private sector. In another study, (Kumhof& Tanner, 2005) opined that domestic banks are very much exposed to government debt because private lending is more risky under the existing legal and institutional imperfections. This exposure puts banks and their borrowers at the mercy of governments' debt policies.

This study aims at building a time series model that can be used to forecast future domestic credit figures to create awareness in the private business community, which will help them to plan. It will also inform policy makers to make informed decisions, which will help in national development. The results of this study will also enrich further, the already good literature that exists in forecasting.

The rest of the paper is organized as follows: Section 2 reviews existing literature relating to this study, section 3 discusses the methods used in data collection and analysis. Section 4 enumerates all the findings of the study and it contains the discussions. Finally, section 5 concludes the study and lists some recommendations.

2 Literature Review

Domestic credit to the private sector (DCPS) has been in focus in recent times, with most of the studies establishing relationships between DCPS and economic growth. (Osman, 2014) applied autoregressive distributed lag (ARDL) as an approach to cointegration to show that there is a positive long-run and short-run relationship between private sector credit and economic growth. (Lane

&McQuade, 2014) established that domestic credit growth in European countries is strongly related to net debt inflows but not to net equity inflows. (Perez, 2017) studied the long run determinants and short dynamics that impact credit growth performance and found that there is a long run relationship between credit growth, domestic banks' equity and non-performing loans. (Shijaku&Kalluci, 2013) evaluated the long-run determinants of bank credit to the private sector and established that there exist an adjustment mechanism that brings bank credit back to equilibrium. Their work further found that lending is positively linked to economic growth. In addition, they proved that banking and financial intermediation, coupled with financial liberalization stimulate higher lending demand.

Other studies have been done on fitting appropriate models to predict relationships between domestic credit and other variables in the context of Africa. In Nigeria, (Emecheta&Ibe, 2014) applied reduced vector autoregressive (VAR) and established a significant positive relationship between bank credit and economic growth. In a similar work, still on Nigerian, (Emenike, 2016) used cointegration method to establish a long-run relationship between monetary policy and private sector credit. (Olowofeso, Adeleke&Udoji, 2015), however, used cointegration to show the existence of a significant positive relationship between private sector credit and output.

Existing literature has shown that little research has been done on Africa in the area of DCPS, and there is no evidence of any study that talks about the DCPS data of Ghana. Another gap in the literature is the lack of the usage of exponential smoothing method (ESM), though several studies including (Kim & Jung, 2018) have praised ESM for its optimal results in the framework of innovative space model. ESM has been used extensively in the sciences, example, (Shao-Hsien & Tsai, 2018) used ESM for prediction and analysis of thermal diffusion for understanding the influence and change brought by electric current on nickel base materials. Also, (Duan&Niu, 2018) applied ESM to forecast lake area changes in Wuhan (Makridakis et al., 1979) investigated the relative accuracy of different time series forecasting methods, and concluded that the exponential smoothing method gives more accurate forecast figures than the many other complicated methods. Meanwhile,(Makridakis and Winkler, 1983) investigated the accuracy of average forecast results obtained from the use of different methods, and found that forecast accuracy improves, and variability of the accuracy among different combinations decreases as the number of methods in the average increases. Furthermore, (Winkler and Makridakis, 1983) concluded from their study that combined forecast obtained through weighted averages were more accurate than the individual forecasts, and even outperforms forecasts obtained from simple unweighted average of the same methods.

Though, there are many approaches proposed by existing literature, the researchers chose ESM because of the popularity it has gained for its simplicity, accuracy in forecasting and having gained the praise of many astute researchers including(Makridakis et al., 1979), for being the best single sample forecasting model.

3 Research Methodology

After a detailed analysis of the pattern in the DCPS data, time series analysis is proposed for forecasting future DCPS values. The method used is the exponential smoothing method with linear trend.

3.1 Data collection method

The data used in this study is a secondary data retrieved from the database of the International Monetary Fund (IMF). It comprises of annual DCPS figures of Ghana as a percentage of gross domestic product (GDP) from 1982 to 2016. This period is chosen since 1981 marks the end of coup d'états in Ghana, hence data from this period is bound to capture the right effects.

The variable being analyzed is DCPS by banks in Ghana; which refers to financial resources provided to the private sector by financial corporations, such as through loans, purchases of nonequity securities, and trade credits and other accounts receivable that establish a claim for repayment. The financial corporations include monetary authorities and deposit money banks, as well as other financial corporations where data are available.

3.2 Data analysis

Exponential smoothing is a relatively simple but robust approach in practice. It is widely used to produce a smoothed time series (Gardner, 1985) and it performs well in empirical studies (Boudoukh, Richardson & Whitelaw, 1997). More importantly, previous studies show that all exponential smoothing methods are optimal forecasts in the framework of innovations state space (ISS).

The analysis is in three parts, firstly, the raw data is summarized to present the data in an intelligible

format for the characteristics of the data to be easily seen, followed by the fitting of the time series model. Finally, residual analysis is done to measure the strength of the model with respect to forecasting. EViews is used to carry out the analysis to achieve the objective of this research.

The forecasting method used in this study is the exponential smoothing method (ESM). Extensive work has been done to study the theoretical properties of ESM, for example, (Gardner, 1985); McKenzie (1984, 1985).

The problem that arises in the fitting of an exponential smoothing method for forecasting is the choice of the most appropriate α. (Gardener, 1985) discusses various theoretical and empirical arguments for selecting an appropriate smoothing parameter. The value of α falls in the interval from zero to one, although, some researchers think that, $0 \leq \alpha \leq 2$ is appropriate for an ARIMA model. (Gardner, 1985) reports that among practitioners, an α smaller than 0.30 is usually recommended. However, in the study by (Makridakis *et al.*, 1982), α values above 0.30 frequently yielded the best forecasts. (Gardner, 1985) finally concludes that it is best to estimate an optimum α from the data, rather than to "guess" and set an artificially low value.

The mathematical model for an exponential smoothing method with Trend is given by:

$$\widehat{DCPS}_t = \alpha DCPS_{t-1} + (1 - \alpha)\widehat{DCPS}_{t-1} + EstimatedTrend \qquad (1)$$

Where, $\widehat{DCPS}_t$ is the forecast at time t

$\widehat{DCPS}_{t-1}$ is the forecast at time t-*1*

α *is* the smoothing constant.

3.3 Residual analysis

The appropriateness of the model for forecasting purposes can be determined by residual analysis. The model is deemed good if it yields small residual values. The two measures normally used are the Mean Absolute Deviation (MAD), and the Root Mean Square Error (RMSE).

$$MAD = \frac{Sum of forecasting errors}{Number of forecasts}$$

$$Let Forecast_i = the forecast value for the period i,$$
$$DCPS_i = the actual value for the period i$$
$$and \varepsilon_i = the error for time i$$
$$then, \quad \varepsilon_i = DCPS_i - Forecast_i$$
$$MAD = \frac{\sum_{i=1}^{n} \varepsilon_i}{n} \qquad (2)$$

$$MSE = \frac{Sum of squares of forecasting errors}{Number of forecasts}$$

$$\therefore MSE = \frac{\sum_{i=1}^{n} \varepsilon^2_i}{n} \qquad (3)$$

$$RMSE = \sqrt{\frac{\sum_{i=1}^{n} \varepsilon^2_i}{n}} \qquad (4)$$

The model with the smallest MAD and/or the smallest RMSE is the best model.

To forecast out of sample, the model is adjusted to accommodate as follows:

$$Forecast n periods away = \alpha(Last value) + (1 - \alpha)(Last forecast) + n(Trend) \qquad (5)$$

4 Results and Analysis

4.1 Descriptive statistics and trend identification

Table 1 Descriptive Statistics

	N	Minimum	Maximum	Mean	Std. Deviation
DCPS	35	1.5423	19.586	9.7640	5.6778

Table 1 above presents the raw data in an intelligible manner, bringing out all the characteristics and features in a summarized format. From the table, the minimum recording of DCPS from the year 1982 to 2016 is 1.5423, which was seen in 1983, and the maximum is 19.585, which occurred in 2016. The series has a mean value of 9.764 and a standard deviation of 5.678.
Figure 1   Time Series of Original Data

Figure 1 above shows that the series contains trend and has an intercept.

4.2 Exponential smoothing model for DCPS

Table 2   Estimated Exponential Smoothing Model

Parameters	
Alpha:	0.544242
Beta:	0.000000
Initial Parameters	
Initial level:	1.160855
Initial trend:	0.471277
Compact Log-likelihood	-73.30356
Log-likelihood	-60.74782
Akaike Information Criterion	154.6071
Schwarz Criterion	160.8285
Hannan-Quinn Criterion	156.7547
Sum of Squared Residuals	1.057703
Root Mean Squared Error	0.173839
Average Mean Squared Error	2.823497

Table 2 presents the best-estimated exponential smoothing model for the data to be a type with multiplicative error, additive trend and without seasonality. The model fitted has very low error values, thus, the root mean squared residuals is 0.17, the average mean squared error is 2.82 and sum of squared residuals is 1.06, which implies that the model will yield good estimates when used in forecasting future DCPS values, which is evident in Figure 2 below. From the model output, $\alpha = 0.5442$ and $Trend = 0.4713$, so, from equation (1), the fitted model is:

$$\widehat{DCPS}_t = 0.5442 DCPS_{t-1} + 0.4558 \widehat{DCPS}_{t-1} + 0.4713 \tag{6}$$
Figure 2   Graph of actual and forecast

4.3 Forecast
Using equation (5), forecast values for DCPS for the years 2017 to 2020 are obtained.

Table 3 Forecast Values

Year	Forecast
2017	19.90
2018	20.68
2019	21.50
2020	22.34

5 Conclusion

In this paper, we have fitted an exponential smoothing model to the domestic credit to the private sector data of Ghana. The fitted model has minimal forecast errors, which proves a good model and is consistent with findings from (Makridakis et al., 1979).

The DCPS forecast values churned out by the fitted model show that the four years that follow the sampling period would see only 13.98% improvement in DCPS (i.e., from 19.60 in 2016 to 22.34 in 2020), which is woefully inadequate, looking at the initial low figure. Meanwhile, government's proposed developmental plan – which includes "one district one factory" and "one village one dam" - is so much private sector dependent, hence will require availability of serious funds to the private sector to fuel it. This is not promising for the future of the private sector of Ghana, and is not in support of the economic growth agenda planned by the government.

For more accurate and reliable forecasting values, we recommend a further research to employ a couple of forecasting methods from the list in (Makridakis and Winkler, 1983), and compute the weighted average of the figures from the individual methods.

Government and regulatory authorities must take a cue from the forecast values churned out by this study and formulate policies that will improve future DCPS values to aid in nation building.

Research on the Equity Pricing of Cross-border M&A under the Belt and Road Based on "Income-market" Orientation

Liu Yi, Min Jian
School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: yiliu1221@foxmail.com, erectoak@foxmail.com)

Abstract: Concerning the phenomenon of cross-border M&A failure due to pricing problems in the Belt and Road, this paper combines the three basic methods of company valuation—asset base approach, income approach and market approach, giving different roles according to their respective scope of application. Starting from the assets, the future cash flow forecast and the equity value of target company, this paper builds a fusion of mainstream evaluation methods of equity pricing system, and strives to make the equity pricing as much as possible to close to the real value of target company, improving the success rate of cross-border M&A in Chinese companies.
Key words: Equity pricing; Cross-border M&A; The belt and road; Income approach; Market approach

1 Introduction

With the continuous progress of the Belt and Road initiative, the pace of "going out" of China's manufacturing companies have gradually accelerated (Ouyang W et al., 2018). According to statistics, China's foreign investment was active in 2016, with the largest amount of money in history. The manufacturing industry topped the list with 200 projects and a total transaction volume of USD 30.11 billion. However, in recent years, there has been an increase in the number of cross-border M&As that do not increase profits (Fonseca J D et al., 2015). According to the statistics of the Ministry of Commerce, the failure rate of cross-border M&As by Chinese companies is as high as 50-70%. In many of the reasons for the failure of M&As, improper pricing is the first to bear.

Market approach is the most important method for value assessment in Western countries. Because it relies more on the market, requiring a greater degree of openness to the domestic market, which limits the application of market law in our country, the Chinese company generally adopts the income approach when assessing the value of target company (Niquidet K, 2010). In recent years, with the continuous improvement of Chinese capital market, the external conditions of Chinese application of market approach have been greatly improved. In today's highly developed economic globalization, only by fully grasping the cutting-edge technologies at home and abroad, contacting the most advanced theories, and combining national conditions, can companies make the most appropriate decisions (Ghoul S E et al., 2010; Blonigen B A et al., 2014). The purpose of this paper is to introduce a market approach that is less preferred when evaluating the value of target companies, and to combine market approach with the cost and income approaches commonly used by Chinese asset appraisers. From the perspectives of pre-merger and post-merger acquisition, companies can be provided more full equity pricing theoretical basis and data support when conducting cross-border M&As, thereby increasing the success rate of cross-border M&As. From a theoretical point of view, each method has its limitations, and the calculated results cannot guarantee the closest to the market's needs (Humphery-Jenner M et al., 2016). This paper combines the two most widely used equity pricing methods, combining the advantages of the two, thus enriching the role of Chinese equity pricing system and helping companies to correctly formulate cross-border M&A pricing decisions in the context of the Belt and Road initiative.

2 Cross-border M&A Equity Pricing Model Based on "Revenue-Market"

In this paper, the idea of cross-border M&A is designed by integrating the three valuation methods that are currently recognized in the world—the asset-based approach, the income approach, and the market approach. In this set of cross-border M&A equity pricing system constructed in this paper, it is mainly divided into three stages to estimate the value of the target company. In the first stage, the application is the asset base approach, through reviewing the relevant financial statements that have been audited, recalculating the market value of the target company's financial assets and real estate, and demonstrating the feasibility of the M&A plan from the perspective of analyzing the scale of the target company (Ghoul S E et al., 2016). In the second stage, the income approach will be adopted to predict the cash inflow of the project in the future through the NPV model, and the risk return rate of the project is used as a discount rate to estimate the future earnings of the target company.In the third stage, the

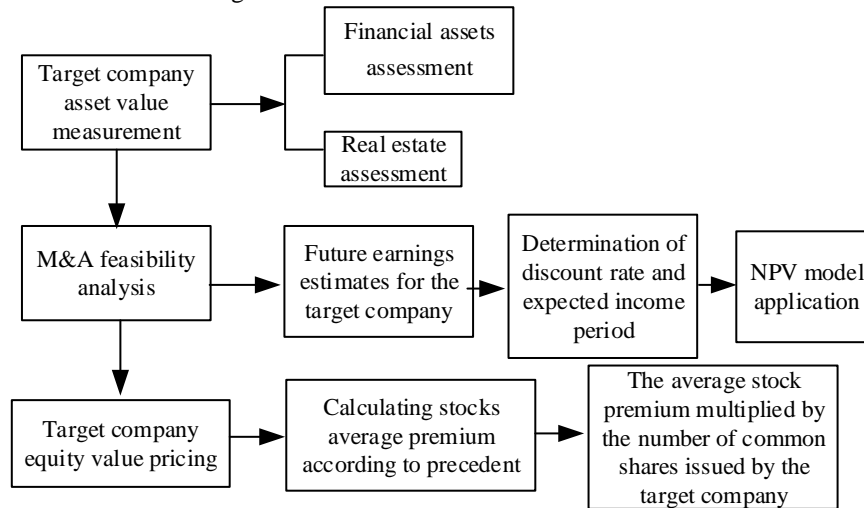
market approach is adopted. Through comparable precedent trading method, similar cases are found in the market, the movement of stock prices in target companies after these acquisitions is calculated, and the volatility of target company stock prices caused by M&As is estimated. Then calculating the ultimate target company's equity capital value based on the estimated stock premium rate. The specific model framework is shown in Figure 1.


Figure 1   Cross-border M&A Equity Pricing Model

3 "Income-Market" Oriented Cross-border M&A Equity Pricing Process

3.1 Target company asset value measurement

This article will mainly take the M&As of resource-based companies under the Belt and Road initiative as a prerequisite. For resource-based companies, most of the valuable assets they own are minerals as well as machinery and equipment that they own. The mineral resources owned by the target companies are often an important consideration for the Chinese companies to evaluate whether or not to conduct cross-border M&As. The assessment model uses a cost summation method, to adjust the book value of various assets in the target company's balance sheet to market value, then estimating the value of the company's overall value by summing the value of investor claims (Huang A G et al., 2016). The formula of asset value evaluation is shown in (1). First clearing the assets and liabilities included in the assessment scope, and distinguishing different asset classes, selecting specific assessment methods to estimate. Then analyzing and summarizing all kinds of results and calculate evaluation values.

$$Asset\ valuation = Asset\ replacement\ \cos t - Entity\ depreciation\ of\ assets - Functional\ depreciation\ of \tag{1}$$

$$assets - Economic\ depreciation\ of\ assets$$

3.2 Analysis of M&A feasibility analysis

3.2.1 Future earnings estimates

For mining companies focusing on resource development, future earnings mainly depend on the market value of the mining resources. If the future price trend of the mineral shows a positive state, it can be reasonably predicted that the company can obtain a more substantial cash flow in the foreseeable future.

Therefore, based on the analysis of the price of mineral resources mined by the target company, a reasonable estimate of the future earnings of the target company will be conducted.

3.2.2 Related parameter settings

In current corporate valuations, the CAPM model and the WACC model are the most commonly used models for calculating discount rates. This paper uses the WACC model to determine the discount rate.

$$R = \frac{E}{D+E} \cdot K_E + \frac{D}{D+E} \cdot (1-T) \cdot K_D \tag{2}$$

Among them, E is the market value of equity capital; D is the market value of debt capital; K_E is the return on investment required by equity capital; K_D is the return on investment for debt capital requirements and T is the applicable income tax rate for the evaluated company.

Determining the revenue period usually needs to consider the product life cycle and market

attitude. Unless clearly specified in the contract, it is difficult to have an accurate judgment. Therefore, this paper will adopt the current routine method of determining the revenue period, assuming that the target company's income period is 5 years.

3.2.3 NPV model application

Using net present value of net cash benefit and net cash investment to calculate net present value and evaluating the investment plan according to the size of the net present value. Net present value equals the total present value of future returns minus the present value of investment, as shown in formula 3.

$$M = BV_0 + \sum_{t=1}^{n} \frac{EVA_t}{(1+r)^t} + \frac{EVA_{n+1}}{(r-g)(1+r)^t} \tag{3}$$

Among them, BV_0 is the initial investment capital; n is the number of years in the forecast period; r is the cost of capital and g is stable growth rate for the follow-up period.

3.3 Company equity value pricing

This paper uses the comparable market transaction method in the market approach. Finding several comparable companies that have similar acquisitions, calculating and analyzing the price changes of these comparable companies before and after the merger, and finally calculating the estimated equity capital value according to the relevant formula. For the selection of comparable corporate transaction activities, this paper will mainly start from the same industry or the same region. Most companies in the same industry will operate in the same industry rules, and changes in consumer attitudes can be more accurately reflected in the operating performance of other companies in the same industry (Yang X et al., 2009; Jiang Y et al., 2011). For companies in the same region, the target companies and comparable companies operate in a similar area, which means that the policies they face will be more consistent.

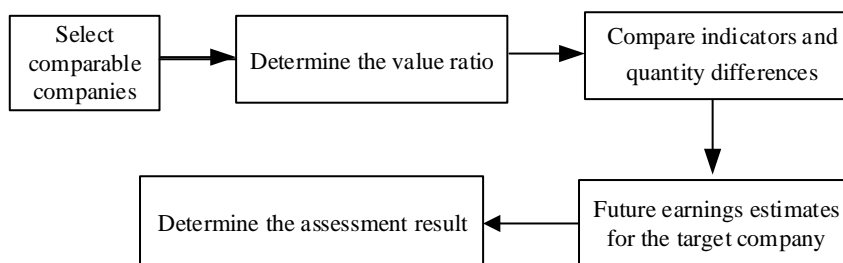
This also makes their impact on the policy similarly reflected. Therefore, comparable trading activities that belong to one industry or one region will be more representative. Calculating an average change value according to the target company stock price change after the Chinese company acquired the related company in the country where the target company was previously located. Then using the change value as the reference value and multiply the target company's common stock price on the agreement day, and then getting the equity value of the target company. Market approach valuation procedures are shown in Figure 2.


Figure 2   Market Approach Valuation Procedure

4 A Case Study

4.1 M&A background introduction

On October 19, 2016, a company in China (hereinafter referred to as "A") and a resource company in Country X (hereinafter referred to as "B") signed a subscription agreement. The main terms are: (1) A subscribes for 207,135,646 ordinary shares issued by B at a subscription price of $0.747 per share, amounting to $154.7 million; the deadline is January 31, 2017 or a later date agreed by both parties. (2)A provides B with a $60 million shareholder loan (ten years, 10% per annum) for repayment of over-financing and operating capital; the deadline is January 31, 2017, or a later date agreed by both parties. In November of the same year, X Foreign Investment Review Committee formally approved A's spending of US$200 million to acquire 51% of B's equity, which is the largest investment project of Chinese private enterprises in X so far.

4.2 M&A equity pricing

4.2.1 Asset valuation

According to the annual audited financial report of B on June 30, 2016, the total value of assets was US$ 342,652, including current assets of US$ 138,295, and non-current assets of US$ 204,357,000. The

composition of non-current assets was mainly mineral development assets; current liabilities were 227,089 thousands of dollars, non-current liabilities of US$7.7 million, both of which mainly constitute interest-bearing liabilities. The assets of B are mainly the resources of molybdenum, copper and iron used in its two major mineral projects. Checking B's resources, as shown in table 1 and table 2.

Table 1   Molybdenum Project Resources

Classification	MT	Molybdenum%	Copper%	Average g/ton
Proven resources	206.8	0.06	0.10	1.5
Control resources	445.4	0.04	0.07	1.1

Table 2   Iron Ore Project Resources

Classification	Ton	Iron%
Control resources	6,110,000	58.90%
Inferred resources	1,160,000	57.20%

4.2.2 M&A feasibility analysis

According to the CPM Group and CRU's forecast for molybdenum prices, this paper will use molybdenum prices at $16.50 per pound. Selecting several analysts to make different price forecasts for iron ore, taking an average of $92.40 per dry metric ton. Analysts believe that the long-term actual copper price will be between 1.60 USD/lb. to 2.92 USD/lb., and the average long-term copper price will be 2.15 USD/lb.

The current capital cost of B=90.78% ×16.60%+9.22% ×7.36% ×(1-30%)=15.50%.

Feasibility analysis of iron ore projects owned by B is shown in table3.

Table 3   Iron Ore Project Feasibility Analysis

Year	2016	2017	2018	2019	2020	2021
Sales revenue	-	28.8	59.2	59.3	56.5	57.2
Operating costs	-	（32.1）	（45.2）	（45.4）	（46.4）	（42.4）
Net profit	-	（3.3）	14	13.9	10.1	14.8
Original investment	（5.9）	（7.5）	-	-	-	-
Net residual value	-	-	-	-	-	-
Net cash flow	（5.9）	（10.8）	14	13.9	10.1	14.8
Discounted at 15%	1.000	0.870	0.756	0.658	0.572	0.497
Present value	（5.9）	（9.396）	10.584	9.146	5.777	7.356

Net present value= -5.9-9.396+10.584+9.146+5.777+7.356=17.567. From the results, the iron ore project is financially viable, and it is expected to bring about a net cash flow to the company in the next five years. Starting from the whole, although only one of the mines of B was analyzed this time, it is expected that the molybdenum mine that has not yet been put into production will have more benefits.

4.2.3 Company equity pricing

On October 19, 2016, according to the data of the X-nation stock exchange, the common stock price of B was US$1.20 per share. Taking into account the ratio of premiums generated by other Chinese companies in M&As/shareholdings of X-state companies in 2016, taking an average of 16.60%, it is expected that the common stock price of B will be US$1.399 per share (US$1.20/share*16.60%+ $1.20/share). According to the agreement reached by both parties, a will subscribe for 51% of the shares, i.e. 207,135,646 shares. Under this condition, a will pay USD 289,782,768, which is approximately USD 290 million. There is a difference of approximately 90 million in the 200 million U.S. dollars agreed in the actual M&A agreement. This is mainly because there is still a subjective component in the selection of comparable trading schemes, and the average value cannot be a true reflection of the premium of the target company's share price that the acquirer can obtain after the merger and acquisition. Although there may be errors, market approach is still a useful method of assessing the value of equity in target companies. Under this method, the equity value of Company B on October 19, 2016 was USD 487,377,990.

5 Conclusion

This article discusses the issue of equity valuation of Chinese companies in cross-border M&A under the background of the Belt and Road. By combining the current three mainstream company valuation methods, a set of value evaluation systems that are more in line with the company's value proposition is constructed. Based on the Chinese context, it may be an innovative fusion that the market approach is combined with the Chinese domestic equity pricing method, which enriched and improved the Chinese company's cross-border M&A equity pricing model. This not only helps companies make rational pricing decisions, thereby increasing the success M&As, reducing the losses caused by improper pricing, but also helping the government to formulate better M&A pricing guidance policies based on the actual situation of companies and international cross-border M&A market conditions. As the equity market changes with each passing day, future research can be combined with the financial instruments in the international market on the basis of the pricing model of this paper to enhance the theoretical and applied value of the model.

The Impact of Risk-taking on Investment Return among Small and Medium-sized Enterprises: Based on the Study of Financial Constraints' Interfering Interaction

Shen Jun, Zhang Renhui

School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070

(E-mail: sjarr@whut.edu.cn, 1715331772@qq.com)

Abstract: Small and medium-sized enterprises are often disturbed by external financing constraints in the process of taking risk, which makes it difficult to benefit from the investment. This paper takes data of small and medium board non-financial listed companies from 2007 to 2016 as the research samples. It is found that higher risk-taking level will bring higher investment return. When small andmedium-sized enterprises choose to take lower risk when they face higher financing constraints, the possibility of benefitting from investment is low. Compared with the low financial constraints, it isfound that, when SMEs face high financial constraints, risk commitment has a weak impact on investment returns, and financial constraints play interfering interaction in the process of SMEs' risk-taking.

Key words: Investment return; Risk-taking; SMEs; Constraints' interfering interaction

1 Introduction

As the basic force to promote the growth of national economy, small and medium-sized enterprises need to enlarge the scale and increase the investment so as to create more wealth. The risk-taking of small and medium-sized enterprise is mainly reflected on the choice of investment plan and expected income level. When enterprises choose to expand investment, they can optimize the allocation of resources and improve the efficiency of capital utilization. When companies choose to take higher risks, they will have greater opportunities to gain returns on investment, and then enhance their competitiveness and expand financial performance (Low, 2009; Cucculelli and Erimini, 2012; Li Wengui, Yu Minggui, 2012). Higherinvestment return must be accompanied by higher risk. Small and medium-sized enterprises do not have enough financial support to afford the financial losses caused by higher risk. Also, it is very easy to fall into financial difficulties for there is no accurate possibility of making profits. Therefore, SMEs are likely to avoid risk when making investment decisions. Risk averse enterprises may abandon some of the investment opportunities which has high risk and positive cash flow. It is not conducive to maximize the value of enterprises (Yu Minggui, Li Wengui, Pan Hongbo, 2013). This conservative investment strategy is not good to the growth and development of small and medium-sized enterprises.

Most of the literatures analyzed the influencing factors of risk-taking from enterprises' inner environment, but seldom considered the external financial constraints when analyzing the relationship between risk-taking and investment. However, this paper believes that the risk-taking preference of small and medium-sized enterprises depends not only on the internal development of the enterprises, but also on the external financial environment.

2 Methodology and Hypothesis

The investment activities of small and medium-sized enterprises are based on comprehensive judgment of investment risk and income. And the shortage of cash flow caused by financial constraints will restrict the investment activities. Therefore, enterprises need to assume the risks rationally according to the financial constraints they face, so as to ensure the profit from the investment.

Lu Xin (Lu Xin, 2013) found that financial constraints will restrict R&D investment, especially for SMEs whose financial constraints are more serious. Excessive investment will make the enterprise face greater investment risk, large scale enterprises have sufficient strength to undertake the risk, but small and medium-sized enterprises may fall into financial distress. However, it is an irrational choice for SMEs to give up investment in order to avoid risk, because it will make the wealth flow to large enterprises, which leads to uneven distribution of resources and poor development of SMEs. Hilary (Hilary, 2009) pointed out that when the company took high risk, it would produce higher R&D inputs, thus improved the company's competitiveness and innovation, and then created more value to ensure the long-term development of the company. Nakano and Nguyen (Nakano, Nguyen, 2012) also believed that although enterprises taken excessive risks had bankruptcy crisis, most of the enterprises' success were

based on the high risk-taking. The risk-taking of the enterprise has two sides. Lv Wendong (Lv Wendong, 2015) and He Weifeng (He Weifeng, 2016) all pointed out that when the enterprise took high risk, on the one side, it would increase the capital expenditure and accumulation, thus accelerate the capital circulation and improve the enterprise's performance, on the other side, such great risk crisis were harmful for enterprises, they were prone to fall into financial difficulties.

Taking risks properly and selecting investment plans accurately can increase the wealth of enterprises and get corresponding remuneration. However, financial constraints restrict the external financing channels and sources, which limit the cash flows of the enterprises, resulting in a failed investment without ideal return. Based on this, this article puts forward the following hypotheses:

H1：Under the premise of continuous operation (not in financial distress), SMEs will get higher investment returns when they take higher risks.

H2：When SMEs take lower risks and higher financial constraints, they will not get enough profits from investment.

Enterprises' risk-taking activities need to consume a lot of resources and have a strong resource dependency (Fazzari et al., 1988; Almeida and Campello, 2007; Lu Xin, Zheng Yangfei, Li Jianming, 2013). If the enterprise cannot get sufficient resources, they cannot invest effectively and may even fail (Li Yanxi, 2007; Lian Yunjun, Su Zhi, 2009). It can be seen that when small and medium-sized enterprises face higher financial constraints, it is difficult to expand investment, and thus the investment income gained by risk-taking is reduced. Although risk-taking can positively promote investment returns, higher financial constraints will impede this promotion. Therefore, this article puts forward the following hypotheses:

H3: Financial constraints play regulating role in the relationship between risk-taking and investment return among SMEs.

H4：Compared with the low financial constraints, SMEs' risk-taking has weak impact on investment returns when they face relatively high financial constraints.

3 Empirical Designs
3.1 Data
This paper takes small and medium board listed companies as research samples and eliminates the followingdata: (1) ST companies; (2) financial listed companies; (3) companies with missing data. Finally, the balanced panel data of 865 small and medium-sized listed companies in 10 years were obtained, and 4401 valid samples were collected. All data were collected from the CSMAR, using Excel 2003 and SPSS 22 for statistics and analysis.

3.2 Model and definition
According to the previous literatures, the calculation of financial constraints was carried out by constructing financial constraint index. Choose the top 33% data of the samples ordered in both size and interest guarantee multiple as a low financial constraint group. Choose the later 33% data of the samples ordered in both size and interest guarantee multiple as a high financial constraint group. The current financial constraint index calculation methods mainly include the multiple discriminant analysis method and the binary logistic regression method. Those methods calculate the coefficient and then calculate the financial constraint index of the company according to these coefficients. Kuang Xuewen (Kuang Xuewen, 2010) used two methods to calculate the index. It was found that the financial constraint index calculated by the two methods was significantly correlated, but the discriminant accuracy of the binary logistic regression model was obviously higher than the multiple discriminant analysis method. Therefore, this paper chooses the binary logistic regression model, and use 5 indexes to build the model. The 5 indexes are Asset Liability Ratio (Lev), Rate of Return on Common Stockholders' Equity (ROE), Financial Slack (SLACK), Increase Rate of Main Business Revenue (BRI) and Current Ratio (CR). SLACK = (monetary capital + transaction financial assets +0.5*net inventory+0.7*net accounts receivable - short term borrowings) / total assets，The model is built as follows:

$$FC = \delta_0 + \delta_1 LEV + \delta_2 ROE + \delta_3 SLACK + \delta_4 BRI + \delta_5 CR \qquad (1)$$

The regression results are shown in Table 1.

Table 1   Financial Constraint Index Model

	B	Wald	Sig.	Maximum	Minimum	Mean	Std. Deviation
Lev	-7.580	82.557	0.000	2.394	0.008	0.315	0.195
ROE	-3.388	36.031	0.000	9.397	-2.706	0.106	0.319
SLACK	4.435	52.612	0.000	0.886	-1.008	0.355	0.207
BRI	-1.019	15.707	0.000	84.992	-0.753	0.308	2.600
CR	0.124	3.236	0.072	104.667	0.227	4.233	6.351
CONSTANT	1.152	7.770	0.005				
Number	1111	1111	1111	1111	1111	1111	1111

At the same time, this paper, referring to the measurement of risk-taking put forward by Guo Jin, Liu Zhiyuan and Peng Tao (2017), uses the volatility of profit to represent the proxy variables of risk and constructs model (2) and model (3). The models take 5 years as an observation time, and measurethe volatility of ROA by rolling computation. Among them, i represents the listed company, t represents the year, k represents the industry of each company, X represents the quantity of industry company, T represents the observation time, the observation period of this article is [t-2, t+2]. Model (2) is used to adjust the mean value of ROA according to the industry and year in order to eliminate the impact of industry and year, model (3) is used to calculate the standard deviation of adjusted ROA. And the adjusted ROA is the risk-taking level of enterprise.

$$\text{ADJ\_ROA}_{it} = \frac{EBIT_{it}}{ASSET_{it}} - \frac{1}{X}\sum_{k=1}^{X}\frac{EBIT_{kt}}{ASSET_{kt}} \tag{2}$$

$$\text{Risk} = \sqrt{\frac{1}{T-1}\sum_{n=1}^{T}\left(ADJ\_ROA_{in} - \frac{1}{T}\sum_{n=1}^{T}ADJ\_ROA_{in}\right)^2} \tag{3}$$

In order to test the relationship between financial constraints, risk-taking and investment income, the FC * Risk is added into the model. The following model is established:

$$\text{Ing} = \beta_0 + \beta_1 FC + \beta_2 Risk + \beta_3 FC \times Risk + \beta_4 LEV + \beta_5 DFL + \beta_6 Growth + \beta_7 Size \tag{4}$$

Since risk-taking takes the volatility of ROA as a proxy variable, it is necessary to adjust the industry and the year when calculating the risk. However, the profits of enterprises are discrepant in different industries, so the corresponding level between risk-taking and investment return is not significant. Based on this situation, we broaden the selection requirements of the variable, and thus set the dependent variable as a measure of whether the enterprise gains from investment. The specific setting situation and the definition of other variables are shown in Table 2.

Table 2   Definition

Variable name	Variable symbol	Variable definition
Investment Return	Inr	Using dummy variables, take 1 when the cash received from investment is positive, otherwise the value is 0.
Financial Constraints	FC	Restrictions on enterprises' external financing
Risk-taking	Risk	The degree of risk preference of an enterprise in making investment decisions
Asset Liability Ratio	Lev	Liability / Asset
Financial Leverage	DFL	Earnings per Share /Change Rate of EBIT
Growth	Growth	Increase Rate of Main Business Revenue
Size	Size	Ln(Total Assets)

3.3 Description

From table 3, we can see that small and medium board enterprises in China are confronted with great volatility in financial constraints, the minimum value of FC is -90.197, and the absolute value is far bigger than the maximum value which is 16.065. However, the average value, 0.187, is still positive.

This indicates that the number of negative values is less, that is, the low financial constraints are less, and most of the enterprises have a big problem of financial constraints. The standard deviation of risk-taking is 0.671, which is small. The maximum of risk is 8.699, the minimum is 0.008, and the difference between them is not huge. It shows that the Risk is concentrated and less volatile. Risk-taking is a common phenomenon in all enterprises.

Table 3　Description

	N	Minimum	Maximum	Mean	Atd. Deviation
FC	1111	-90.197	16.065	0.187	4.097
Risk	1111	0.008	8.699	0.118	0.671
Lev	1111	0.008	2.394	0.315	0.195
DFL	1111	0.746	1.239	0.999	0.109
Growth	1111	-0.753	84.992	0.308	2.600
Size	1111	18.593	25.705	21.454	1.063
Valid N	1111				

4 Results

In this paper, the multiple discriminant analysis method is selected to test the model (4) because hypothesis 2 is the judgment of the enterprise's possibility of benefitting from investment in different financial constraints and risk-taking. Using the multiple discriminant analysis method, the enterprise can make discrimination on the profit of investment according to its internal development situation, and can also have a more accurate understanding of investment plan.

The non-normalized Fisher discriminant function is as followed：

$$Inr = -18.705 - 0.343FC + 0.168Risk + 0.07FC \times Risk - 5.568Lev + 1.533DFL - 0.354Growth + 0.889Size$$

Small and medium-sized enterprises are easy to be trapped in financial crisis, which leads to bankruptcy. Although the coefficient of Risk is positive, it has to keep continuous operation before benefitting from high risk investment. Thus, hypothesis 1 is proved. The result of the discriminant function also shows that the coefficient of FC is negative, and the coefficient of Risk is positive. It indicates that the lower risks and higher financial constraints SMEs have, the lower possibility for them to get profit (divided into Inr=0 group), which proves H2.

Table 4 is the result of binary logistic regression of model (4). From the list I we can see that financial constraints and investment benefits have a significant negative correlation. When enterprises face higher financial constraints, it will lead to the failure of the enterprises' benefits. The coefficient of financial constraints and risk commitment is positive. It means that in the significant level of 10%, the financial constraints and risk-taking are positively related to enterprises' investment returns. Financial constraints play a regulatory role in the relationship between risk-taking and investment return among small and medium-sized enterprises. Hypothesis 3 is verified. From table 4, it's also found that the coefficient of FC*Risk is far less than the coefficient of Risk, which indicates that financial constraints play interfering interaction. Compared with the lower financial constraints, the impact of risk-taking on investment returns is weak among SMEs when they face high financial constraints. Hypothesis 4 is verified.

Table 4　Empirical Results

	Whole Samples	High Financial Constraint	Low Financial Constraint

5 Conclusion

The results show that financial constraints interfere with the impact of risk-taking on investment returns. In the face of higher external financial constraints, small and medium-sized enterprises are limited in financing channels. They cannot provide sufficient resources to support venture capital, and the free cash flows of SMEs are reduced. Thus, it is difficult to get return from investment. At the same time, because of the existence of financial constraints, the utilization ratio of capital is reduced. Even if SMEs are willing to take higher risks and expand investment, they cannot get high remuneration. This situation hinders the growth and development of small and medium-sized enterprises, and even makes it easier for them to fall into financial crisis. The risk-taking level of SMEs requires managers to consider carefully after a comprehensive measurement. Risk taking is the objective fact of each enterprise while financial constraints are the variables that can be effectively controlled through government's regulation and enterprise's management. Therefore, for the development of small and medium-sized enterprises, it is necessary to reduce the financial constraints and concentrate on reducing financing difficulties. Only then can SMEs improve the efficiency of investment that caused by the high risk-taking.

Study on Management of the Tax Risk of Small and Medium-sized Enterprises

Lu Mengqiu, Li Jingjing, Du Juan
Business School, Wuhan Huaxia University of Technology, Wuhan, PR China, 430000
(E-mail:645917249@qq.com, 1527676791@qq.com, 375169546@qq.com)

Abstract: At presentsmall and medium-sized enterprises(SMEs) play an integral part in the national economy in China. Through theoretical research, this paper analyzes the nature of the problem, and combines the empirical analysis of the questionnaire to study the problems existing in the current level of tax risk management of SMEs. First of all, this paper analyzes the causes of the tax risks of SMEs and the tax risks of SMEs by combining the characteristics of SMEs and the theoretical models of management and psychology (opportunism exist, boundedrationality hypothesis, information asymmetry theory, etc.). The reasons for the tax risks of SMEs are divided into internal and external reasons. The purposeof both theoretical research and empirical research is to solve problems, therefore, taking reference of relevant theories and results of empirical research, from some aspects such as the tax risk management goal, management organization, risk response, information communication, supervision improvement, and risk early warning and so on
Key words: Medium-sized enterprises; Tax risk; Management; Tax

1 Introduction

Due to the relatively heavy burden of taxation, the competenceof SMEs in dealing with tax problem will directly affect their successes and failures. If this problem can be properly treated, the enterprise can gain a rapid development, but if not, enterprises will face huge lost for that or even bankruptcy. Therefore, the tax risk ofSMEsserves as the same importance of any other risk, especially for those with a rapid growth cycle, and to some degree, it even decides the survival and development of these enterprises.

The very first researcher of the growth process of SMEs is professor, Lawrence L. Steinmetz who proposed the S-Curve was able to authentically reflex the growth process of SMEs. It mainly analyzes the direct control phase, command and management phase, indirect control phase and department organization phase. In this paper, by comparing many studies of the life cycle of SMEs both at home and abroad, the researcher will point out there are two phases in the life cycle of those enterprises; development and selection phases. Development phase can be divided into three periods: start-up stage, growth stage and mature stage; And selection phase has two cases: one is going directly into the recession stage, another is coming into metamorphosis stage and turning into a large-scale enterprise with new life cycle. See Figure 1.
Development phaseSelection phase
Figure 1   Growth Cycle Chart of Small and Medium Sized Enterprises

(Michael Carmody, 2008) believed tax risk was uncontrollable, applicable law or regulation frequently changed, and the criteria of accounting and corporate management were changeable. All

these would lead to tax instability and assets risk. Liu, Rong (2010) pointed out tax risk was a kind of uncertainty in taxation responsibility, mainly existing in the transaction process as well as financial reports and the compliance of relevant laws and regulations. Wang, Zhenhuan (2011) concluded that tax risk was the possibility of paying an overdue tax, paying fine or receiving criminal sanction out of the violation of the tax law. Cai, Chang (2012) suggested tax risk was the possibility of future loss of interest because enterprises didn't correctly follow the tax law. And it included two cases: paying more or less taxation than asked. Su, Lijie (2014) concluded that there were two kind of problem in taxation: one was tax evasion, and enterprises would pay fine or even be involved in penal law; Another was the inappropriate understanding and improper use of tax law, leading to tax overpaid. In an analysis report in 2017 from Jiangsu Branch, Industrial and Commercial Bank of China, it was pointed out that tax risk refers to that tax payers didn't pay their taxation strictly as the tax law or didn't rightly understand tax law terms and preferential tax policies, resulting in paying more or less in taxes.

From the studies above, it can be found that many experts extended the definition of tax risk that can be understood in these two ways: one is the possibility of punishment by tax authorities because of the paying less in taxes; the other is the possibility of unnecessary taxation burden out of the incorrect understanding of tax law or policies.

2 Theories Related to Corporate Risk Management

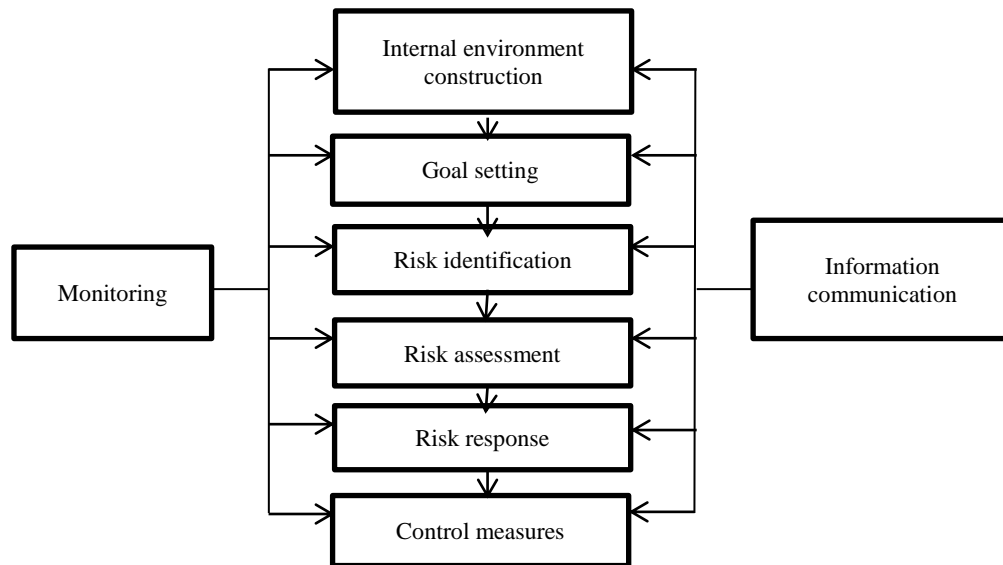
The whole process of risk management is progressive and all factors are closely connected. The basis is corporate internal environment. By setting reasonable management goals, all possible risk will be identified, and a series of risk assessment would be made. And information communication and monitoring are two factors that affect the whole process of risk management and timely correction will be made. These 8 factors are an organic integrity and they are interactive in the process of risk management. See Figure 2 for the specific framework:


Figure 2   Flow Chart of COSO-ERM Risk Control

Combining with the theories discussed above, this paper believe corporate tax risk management can be defined as: in order to avoid suffering from lost for tax risk, establish a set of complete tax risk management system, including management of goal setting, construction of tax risk organization, identification of tax risk, establishment of tax organization, internal control of tax risk, information communication of tax risk as well as monitoring system f tax risk.

3 Analysis on the Reason of Tax Risk

From the literature review, it was found tax evasion was the most fundamental reason of tax risk. However, this paper believe this is a misunderstanding: many experts and scholars are tackling with tax risk by taking enterprise as a whole, but in practice, all departments are independent, containing decision-making department, production department, sales department and financial department. There is a game relation among them and this often leads to tax risk.

3.1 Analysis on the internal reason of tax risk insmall and medium-sized enterprises (SMEs)

The internal reason for tax risk have: the lack of tax law leads to the weak awareness of tax risk defense and control, as well as insufficient internal control. Of them, the lack of awareness in tax risk mainly reflect in fun-raising, investment, production, conclusion of contract, fulfillment of contract and product distribution. In comparison of large-scale enterprise, SMEshave comparatively less fund-raising channels and are facing heavier market pressure. In face of clients and suppliers, they are usually in a passive position. Therefore, many SMEs often only stress the importance of maximizing the interest and ignore the management of tax payment and finally suffer from larger loss at tax cost. The incomplete internal system is primarily caused by the problems in production process. These problems are easier to lead to business risk, and of course include tax risk. Compared with large-scale enterprises, SMEs have a looser management in personnel quality, which would ask for higher cost. These in return result in problems in financial management and internal control, which also play a core role in the tax risk.

3.2 Analysis on the external reasons of tax risk in small and medium-sized enterprises (SMEs)

The external reasons for tax risk have: the defective tax legislation, tax collection and management, as well as changes in tax laws. Tax law and regulation can easily and directly affect the tax risk of enterprises. So there is little difference in the reasons of this kind of risk between large-scale and SMEs. The difference lies in the attention and awareness of relevant changes because the personnel quality is higher and there is better monitoring in large-scale enterprises. Moreover, the ability of tax risk control of these enterprises are stronger than that of SMEs. Under this circumstances, the former can easily decline its risks in taxes. For the latter, the lack of outside information directly affects the decision-making abilities of the leadership. Sometimes, even they master efficient information, out of their incompetency, they cannot respond timely. Thus, this kind of tax risk will lead to a bigger influence on SMEs.

4 Construction of the Tax Risk Management Mechanism inSmall andMedium-sized Enterprises (SMEs)

Based on COSO-ERM, this chapter takes tax risk of SMEs as one of the business risk, and through constructing the tax risk management mechanism of SMEs, it is aimed at helping them efficiently control tax risk.

4.1 Mechanism framework of tax risk management in small and medium-sized enterprises (SMEs)

In September 2004, COSO issued the Enterprise Risk Management-Integrated Framework (COSO-ERM) which definitely stated the 8 components of enterprise risk management: internal environment, goal setting, risk identification, risk response, control measurement, information communication as well as monitoring. This whole process is closely connected. Taking tax risk as one of the business risk and referring to the enterprise risk management framework, this paper will construct a tax risk management mechanism for SMEs. See the specific management mechanism framework in Figure 1.

4.2 Management goal of tax risk in small and medium-sized enterprises (SMEs)

The tax risk of SMEs is different from investment risk, because common business risks are non-juristic, while the investment risk of SMEs is juristic. From a legal perspective of, the goal of tax risk management is "zero risk", yet in reality, it's extremely hard to reach "zero risk". The main reason lies in the definition for tax risk that has been elaborated above: on the one hand, the violence of tax law and regulation will be punished; And on the other hand, although paying higher taxes don't violate any law or regulation, it can cause loss to enterprises. Thus, it also belongs to tax risk, especially for SMEs. To earn bigger market, share and extend sales channel, some enterprises would rather to pay more taxes to gain survival opportunity without regard to tax cost. Thus, in the sight of enterprise survival and under the circumstance of without violating law, these enterprises can have a better control of tax risk and make corresponding defense measures. Furthermore, in many cases, owing to information asymmetry, opportunism, etc., these enterprises would passively face bigger tax risks. Thence, zero tax risk is not a simple subjective judgement, but a relatively complicated tax risk management question. This paper holds the idea that the goal of tax risk management of SMEs should not be zero tax risk, instead it should be to decrease tax risk and avoid loss to greatest degree through efficient internal communication and identification of potential tax risk, on the basis of abiding by the tax law. And then, to propose some constructive and targeted suggestions to the production and business process.

4.3 Improvement in monitoring mechanism insmall andmedium-sized enterprises (SMEs)

As analyzed above, the internal control and risk management system is only formulaic burdens,

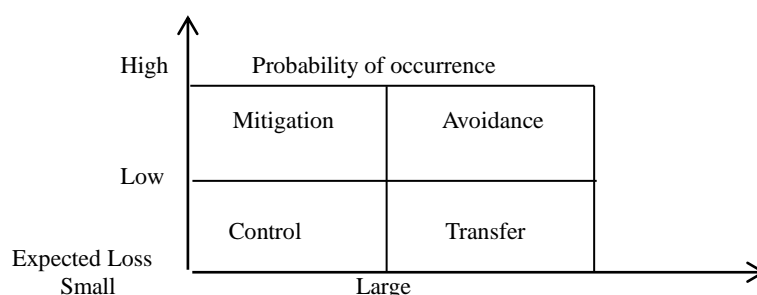
and it didn't be strictly followed during the operation process. Therefore, in order to make sure the tax risk management system in SMEs is efficiently working, the researchers designed a monitoring and improvement mechanism in tax risk management. In the assessment, the following three aspects should be considered: first, the cost and feasibility of the implementation; second, the impact of the risk; and third, the full comparison of the various programs. After the assessment, the company should choose the appropriate solution according to its own situation. Since the probability and degree of impact of various tax risks are different, a four-dimensional space map can be constructed according to the probability of occurrence of tax risk and the degree of influence (see Figure 3), and four different coping strategies are adopted. For tax risks with high probability of occurrence and small degree of influence, the corresponding strategy is risk mitigation; for tax risks with low probability of occurrence and small degree of influence, the corresponding strategy is risk control; for tax risks with high probability of occurrence and high impact, the corresponding strategy is risk avoidance; for tax risks with low probability of occurrence and high impact, the corresponding strategy is risk transfer.


Figure 3   Different types of tax risk response for SMEs

It should be noted that in the choice of tax risk strategy, SMEs should be different from large enterprises. Because large companies usually have a wide range of business. If there is a problem with a business, it often does not have much impact on the entire enterprise. For SMEs, their business operations are relatively simple and their capital operations are relatively tight. Once the tax risk of a business causes losses, the impact on the enterprise is much greater than that of the large enterprise. Therefore, SMEs should adopt strategies to avoid and transfer tax risks as much as possible, and use tax mitigation strategies with caution to make their tax risks within the most controllable range. See the specific content in Table 1

Table 1   Tax Risk Processing System Function Table

Corporate Management Tax Risk Management (Finance Department)	Solution of tax risk
Avoid corporate tax risks	Sell, abandon a product or a business, prohibit unacceptable tax risk activities, reset policies and configuring resources
Control corporate tax risk	Regularly evaluate and monitor tax risks to develop an emergency response plan
Mitigate corporate tax risk	Rationally adjust business model and reduce tax risk trigger probability
Transfer corporate tax risk	Separate businesses or products that face high tax risks through separation, leasing, outsourcing, etc.

Based on the above analysis, we will enter the tax risk summary system. The work of the system is mainly to summarize and analyze the effects of various tax risk response strategies, and to provide reference materials for the revision and improvement of relevant management systems including tax risk management. The tax risk summary system can be performed in the following four steps, as shown in Table 2.

Table 2   Tax Risk Summary System

The tax risk summary system	concrete content
Examination	Check the causes of tax risks, related warnings and countermeasures
Evaluation	Conduct a comprehensive evaluation of tax risk management, including the evaluation of the effects of tax risk warning and tax risk assessment

Continual Table 2

The tax risk summary system	concrete content
Improvement	Suggest improvements to the problems existing in the tax risk management system and implement them in relevant departments
Archive	Establish a tax risk response strategy file to provide experience and reference materials for the improvement and improvement of corporate tax risk management

5 Conclusion

It's comparatively late for China to start its studies in corporate tax risk management, so there are only a few study results can be found. In this paper, the researcher analyzed the reason, current situation, construction of management system of tax risk in SMEs, and two main conclusions were achieved: 1, This paper analyzed the mechanism of tax risk in SMEs, and explained the reason of tax risk from theoretical perspective. 2. This paper constructed a set of tax risk management mechanism by referring to COSO-ERM model, and from the management goal, management organization, tax risk identification and assessment, information communication, monitoring improvement, tax risk warming and tax risk response, it established a tax risk management system for SMEs, which is especially beneficial for the mechanism construction of tax risk management and monitoring. Since tax risk belongs to Management Science, this paper studied corporate taxation from the perspective of Management Science and psychology.

As one of its innovations, this is an interdisciplinary research. But it's unavoidable to find some shortcomingsin this study, and for lack of Management Science and psychology knowledge, the theoretical model has some defects. In the future, we should have built up a series of tax risk 'early warning' system to help SMEs to detect signs of tax risks. As a consequence, the managers of SMEs are able to assess and analyze potential tax risks and then manage risks more effectively, and utilize tax risk 'early warning' system to conduct early -warning analyses of tax risks of enterprises.

Text Sentiment Analysis of Garbage Incineration "Nimby" Event Based on K-nearest Neighbor Algorithm

Huang Pan, Yang Qing
School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: 2439217886@qq.com, yangq@whut.edu.cn)

Abstract: In order to identify the emotional tendency of garbage incineration "Nimby" events, a K-nearest neighbor algorithm is proposed to analyze the events by analyzing the structure of the text and the characteristics of emotional expression. The text of garbage incineration "Nimby" case is divided into partial emotions and overall emotions. Through the construction of the model, the overall sentiment of the entire event text is calculated and the construction of a garbage incineration "Nimby" case library is facilitated.
Key words: Garbage incineration; Nimby; K-nearest neighbor algorithm; Sentiment analysis

1 Introduction

Garbage incineration is the best way to dispose of domestic waste as "reduced, harmless, and resource-based" and has caused the country's great attention and importance (Chen Y H, 2015). However, during the process of waste incineration projects, it is faced with the problem of "difficulties in landing" caused by "Nimby" (He Yanling, 2009). The existing research on the "Nimby" of MSW incineration remains at the problem solving and management suggestion level (Li Y, Liu L, 2017). With the study, the best way to achieve the transformation of the crisis is to build a library of waste incineration "Nimby" crisis resolution cases, and to better understand the emotions of "Nimby" events through text sentiment analysis of historical events. Through the text extraction of garbage incineration "Nimby" cases, considering the internal structure of the text and the characteristics of emotional expression, a sentiment analysis method based on the K-nearest neighbor algorithm is proposed, and a hierarchical model of sentiment analysis is built, which is conducive to the extraction of textual knowledge.

2 Text Emotional Model

In order to accurately analyze the complex emotions in the text, the concepts of global emotion and partial emotion are first introduced (Ravi K, Ravi V, 2015; Zhao Yanyan, 2010). Global and partial are a pair of philosophical categories that reflect the interrelationship of things and the process of their inclusion and combination, and they are a universal link that reveals the interaction and relationship between the whole and part of objective things (Yang L, Jian Z,2013; Hesse B W,2015). The overall situation is the whole, which is the sum of all parts and aspects of things. It has leadership, decisive, and major roles for each part and all aspects (Stavrianou A, 2013; Boiy, Erik, Pieter, 2007; Haddi E, Liu X, Shi Y, 2013). Through analysis, we find that the emotions in the text also conform to philosophical laws such as global and partial. Through the analysis of a large amount of corpus information, the emotions in the text are divided into two types: global emotion and partial emotion. Global emotion refers to the emotion expressed in the entire text; and partial emotion refers to the emotion expressed in a certain part of the text. This specific part can be a word, a phrase, a sentence, or a paragraph. Each partial emotion in the text interacts and interacts with each other, ultimately determining the overall emotion of the text. (Figure 1)

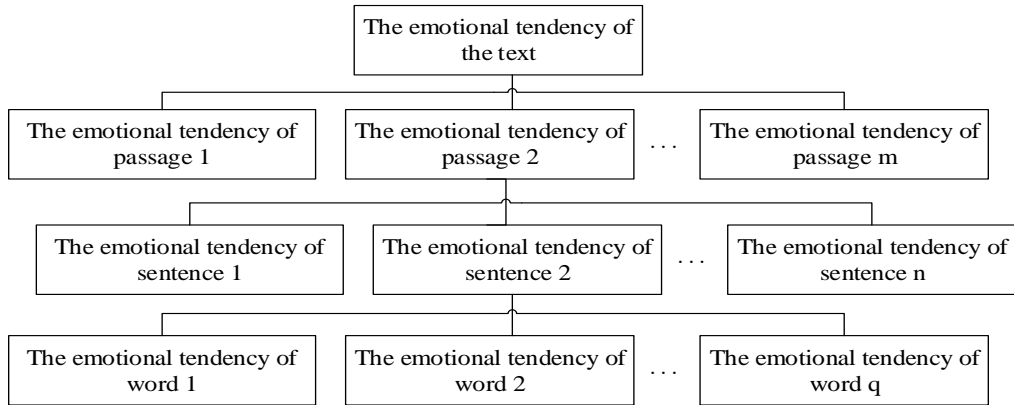
According to the semantic structure of the text, the hierarchical model is divided into four levels: T is the emotional tendency of the text, $p_1, p_2, p_3, \ldots, p_m$ are the emotional tendencies of each natural segment, $s_1, s_2, s_3, .., s_n$ are The emotional tendency of each sentence in the segment, $w_1, w_2, w_3, ..., w_q$ is the emotional tendency of the word. According to the partial and overall analysis of emotions, the emotional tendency of words determines the tendency of sentences to be lighter, and the emotional orientation of sentence sentences determines the emotional tendencies of natural segments. The emotional information of natural segments determines the overall emotional orientation of the text. This hierarchical emotional model clearly shows the internal emotional context of the text. Through this model, the emotion of the text can be analyzed in multiple angles, fine-grained levels, and levels.


Figure 1   Textual Emotional Representation Model

3 Sentiment Analysis

According to the hierarchical analysis model established, the text sentiment calculation method can be divided into two steps: ①Calculate and obtain the emotional sentiment value of each paragraph in the text, that is, partial emotion; ②Obtain the overall emotion of the text according to the partial sentiment calculation. The following will elaborate on these two steps.

3.1 Partial sentiment analysis

First, determine the emotional orientation of each segment. The emotion recognition of paragraphs is regarded as the emotional annotation of sentences in paragraphs, so the conditional random field model can be used. Because the subjective content and objective content of the segment exist at the same time, if the objective content is eliminated first, the subjective content is directly analyzed by emotion, which is inevitably effective in avoiding the influence of the objective content on the emotional judgment. Based on this, we propose a two-tier CRF model to analyze the segment.

The model specifically includes the following two steps:

(1) In the first-level CRF model, the subjectivity and objectivity of sentences included in the segment are first marked. In this way, through the labeling of the first layer, the objective sentence is filtered, leaving only the subjective sentence to be processed, avoiding the influence of the objective sentence on the next level.

(2) The sentence marked as subjective is taken as the input of the second-level CRF model, and the evaluation of the sentence in the second layer is completed. According to different layers of tasks, CRF models at different levels adopt different model features. The first layer of model features are subjective features. We define sentences that contain emotional words as subjective sentences. Therefore, subjective features are emotional words. For sentences containing emotional words in the emotional lexicon, and mark them as subjective sentences, otherwise mark them as objective sentences. The characteristics of the second layer model are the characteristics of appreciation. The sentiment words in the comprehensive emotional vocabulary we have established include two attributes, one is the evaluation of emotional words, and the other is the value of devaluation (an inclination tendency is assigned to 1, a depreciation tendency is assigned to -1, and a neutral emotion is assigned to 0). For the emotional words contained in a sentence, the devaluation of the sentence is taken as a feature of the model. Through the above steps, the emotion of the sentence in the paragraph is completed, and the emotion of each paragraph can be determined.

3.2 Text sentiment analysis based on K-nearest neighbors

Emotional tendencies include two types: Commendatory and derogatory, so emotion recognition can be regarded as two types of classification problems, namely the identification of defamation and derogatory. Based on this, the K-nearest neighbor algorithm is used to identify the sentiment of the text. The algorithm is a simple, effective, non-parametric method. Its essence is a predictive monitoring algorithm. Its rules are data samples. In the following, taking two classification problems as examples, a formal description of the K-nearest neighbor method is given: Based on the vector space model (VSM), each instance is considered as a point (vector) in Rn space. Assume that the instance data of n class identifiers are (X_1, y_1), (X_2, y_2), ... (X_n, y_n), where X_i is the vector representation of the instance, and y_i is the class corresponding to the instance. The value of the category is 0 and 1, which means two types. For a given instance x, its type can be judged by Equation (1):

$$y = \frac{1}{k} \sum_{x_i \in L_k(x)} y_i \tag{1}$$

Where: if the y value is greater than the given threshold of 0.5, X belongs to class 1; when it is less than 0.5, X belongs to class 0. Where $L_k(x)$ represents the value of the closest K instances to a given instance X. In practical applications, in order to improve the accuracy of the K-nearest neighbor method, an improved K-nearest neighbor algorithm-weighted K-nearest neighbor method is often used. In this algorithm, the decision weights are calculated for each instance. For X, the distance between X and the K nearest neighbors $(X_1, y_1), ..., (X_K, y_K)$ is defined to be $d_1, ..., d_K$, respectively. The decision weight β_i is calculated as follows:

$$\beta_i = 1 - \frac{d_i}{\sum_{i=1}^{k} d_i} - \frac{k-2}{k} \tag{2}$$

Weight-based neighboring decision rules can be described as:

$$y = \frac{1}{k} \sum_{X_{i \in N_K(X)}} \beta_i * y_i \tag{3}$$

After determining the K-nearest neighbors of instance X, the decision weights of each instance are calculated, and the size of the decision weights is used to determine the extent to which they play a role in predicting the category assignment of X.

For a text's global emotion, we use a weighted K-nearest neighbor method for all partial emotions in the text to obtain the overall emotion of the text. Because each segment in the text has different weights, each partial emotion plays a different role in affecting global emotions. Relatively important segments of emotions exert a great influence, while relatively unimportant segments of emotions play a minor role. The weighted K-nearest neighbor method usually determines the weight according to the distance from the target point, but in the global sentiment prediction, the weight of each segment is not determined according to the distance of the traditional meaning, but according to the importance of the segment itself. definite. Therefore, the calculation of the weight is also different from the weight calculation in the weighted K-nearest neighbor algorithm. According to the above analysis, the calculation of global emotion is as follows:

$$P(T, s_j) = \sum_{i=1}^{k} P_T(P_i, s_j) W_i \tag{4}$$

Where: $P(T, s_j)$ represents the global sentiment of the text T, and $\sum_{i=1}^{k} P_T(P_i, s_j)$ represents the cumulative sum of emotions in the middle segment P_i of the text T, ie, the partial emotion of the text. When $P_T(P_i, s_j)$ is a propensity, the value is 1, when it is derogatory, the value is -1, and when it is neutral, it is 0. w_i denotes the weight of segment P_i.

The calculation of segment weights is a key step in determining global emotions. Each segment in a text has a different contribution to the text. In this article, we define the segment's weight more specifically as the contribution rate of the segment, and the contribution rate refers to the contribution of the segment to the text theme and content. The title and sentence are respectively expressed as vectors of feature items. The smaller the angle between the vectors, the higher the similarity between the title and the sentence. Sentence and title similarity. Calculated as follows:

$$\text{Sim}(S_i, T) = \frac{S_i T}{\|s_i\| \|T\|} \tag{5}$$

Where: T is the vector of the title, S_i—the vector of the sentence. The similarity threshold δ is determined by experiments. Through repeated experiments in this paper, δ = 0.75 is finally determined. When the similarity between a sentence and a title is greater than the threshold, the sentence is considered to be similar to the title, and the sentence is considered to contain the sentence. The segments are relatively important to consider all the above factors. The contribution rate of a segment is defined as follows:

$$v_{C_i} = 1 + \frac{S(P_i)}{N_{P_i}} + \alpha \tag{6}$$

Where: v_{P_i} represents the contribution rate of the i-th segment, N_{P_i}—the number of all sentences contained in segment P_i, and $S_{(Pi)}$—the subject sentence contained in segment P_i Number, α—the value given when the segment contains the first or last segment, n—the number of all sentences in the segment P_i that are similar to the heading. The value of α must be determined by statistical analysis of the experiment. Through the above calculation steps, the contribution rate of a segment, that is, the weight of a segment can be determined. Obtain the emotion of the segment and the weight of the segment, and use a weighted sum predict the overall emotion of the text.

3.3 Results

This article crawls through webpages and obtains more than 200 web pages. After data cleaning and screening, we chose to retain 29 garbage incineration "Nimby" texts. The sentiment evaluation of text is divided into two parts. First, the partial emotion of the text is obtained, and then the overall emotion of the text is obtained by the K-nearest neighbor algorithm. Firstly, the two-stage CRF model is used to identify the emotions of garbage incineration "Nimby" incidents, and a comparative analysis is used. There are different analysis methods (machine learning methods, Bayesian classifiers) to determine the emotional analysis of the entire text sentence. Andthe results are as follows:

Table 1   Results of Text Sentiment of Garbage Incineration "Nimby" Event

Case	1	2	3	4	5	6	7	8	9	10
Commendatory	42.35	42.72	45.09	40.49	42.97	42.345	44.795	42.46	50.735	43.86
derogatory	57.65	57.28	54.91	59.51	57.03	57.655	55.205	57.54	49.265	56.14
Case	11	12	13	14	15	16	17	18	19	20
Commendatory	37.15	51.29	49.29	66.33	40.44	39.47	51.14	51.03	17.28	57.55
derogatory	62.85	48.71	50.71	33.67	59.56	60.53	48.86	48.97	82.72	42.45
Case	21	22	23	24	25	26	27	28	29	
Commendatory	51.95	46.26	46.35	62.61	49.6	45.31	45.445	45.82	49.03	
derogatory	48.05	53.74	53.65	37.39	50.4	54.69	54.555	54.18	50.97	

4 Conclusion

Based on the analysis of text structure and the characteristics of emotional expression, this paper proposes to establish a "global + local" sentiment analysis model for garbage incineration "Nimby" events, and carries out a two-stage analysis of the text. Firstly, the two-level CRF model is analyzed, and then the weighted K-nearest neighbor algorithm is used to make the text sentiment analysis more scientific.

Research on the Countermeasures of Prevention and Resolution of Local Government Debt Risk

Zhao Jiayi, Zhao Xin'e
School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: 1041815063@qq.com, zxehb2001@163.com)

Abstract: Based on the recent measures proposed by the Hunan Provincial Finance Conference to prevent local government debt risk, this paper firstly analyzes the status quo of local government debt, summarize the types of local government debt, and then focuses on clarifying the scale and structure of local government debt in China by collecting and analyzing relevant data. The amount of China's local government debt is large, but the growth rate is relatively stable, and the debt risk is controllable. On this basis, it analyzes the causes and consequences of government debt risk. Finally, it puts forward measures to prevent and resolve local government debt risk, and looking forward to the development trend of local government debt risk in the future.
Key words: Local government; Debt risk; Debt status; Risk management

1 Introduction

Recently, Hunan Province held a high-level financial work conference and adopted the measures of "Stop the construction of a batch of projects, delay the construction of a batch of projects, reduce a part of the debt, and cancel a part of the debt to resolve stock debts and strictly control the increase in debt; Besides, strictly controlling land supply, project management, corporate bond issuance and rectification of platform company. These four major points are adopted to prevent local government debt risk. At this point, the prevention of local government debt risk has been elevated to a new height by the central government.

All over the world, the problem of local government debt has caused at least three crises including Latin American countries debt crisis in the 1980s, Southeast Asian financial crisis and financial crises in Argentina and other countries in the 1990s, and recently the global economic recession is caused by government debt problems in European and American countries. All indicate that the problem of local debt risk is an important factor that hinders world peace and development.

On account of the general concern of local government debt risk, this paper makes analysis of government debt risk categories and status quo based on the existing theoretical results, explores the origin of debt risk from the source combined with the fishbone chart, and then puts forward the countermeasures to prevent and resolve debt risk.

2 Types and Current Situation of Local Government Debt Liability

2.1 Types of local government liability

Local government liability appears under the influence of reformation in China's socialist market economic system , accompanied by the concurrent transformation from planned economic system to market economic system, specifically referring to the governmental conducts aimed for raising capitals，which could be explained as to widely contract loans to investors under the guarantee of government credibility. As an important form of government income, local government liability is also an important tool for macro-control of the economy and a redistribution form of national income.

According to Figure 1, the risk of local government liability can be classified from different standards. This paper chooses the method of "matrix analysis" to analyze government liability. First, government liability can be divided into direct liability and contingent liability, depending on whether specific conditions are required for its occurrence. Direct liability will occur under any conditions, while contingent liability is incurred under certain conditions where the government needs to assume certain obligations. Second, according to the legal confirmation, local government liability can be divided into implicit liability and explicit liability. Implicit liability is a kind of debt that has not been agreed by law or contract and has to be assumed due to some external factors, while explicit liability is the type of debt that must be undertaken because of legal contract. If the two ways of making classification are combined, the local government liability can be divided into four types: direct and explicit liability, direct and implicit liability, contingent and explicit liability and contingent and implicit liability.

Direct explicit liabilities refer to the credit debts that local government owns on the basis of the existing conditions and in accordance with the law, which are mainly for the local infrastructure

construction, including enterprises, land resources and local public resources.

Direct implicit liabilities refer to the credit debts indirectly owned by local governments under existing conditions and without licit accordance, including local pension funds and health insurance funds under direct control.

Contingent liabilities refer to the credit debts that are legally contingent upon a particular future condition, including the capitals borrowed from domestic and foreign financial institutions, units and individuals with government guarantees.

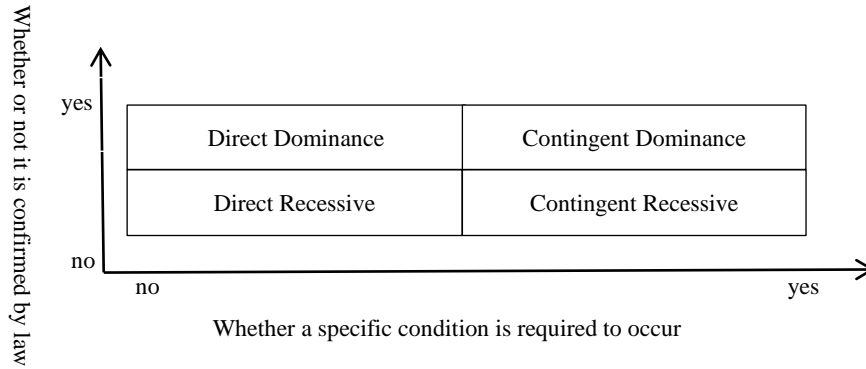
Contingent liabilities are liabilities that may occur under certain conditions without legal or contractual accordance, including official credit, loss reporting, and natural disaster liabilities.


Figure 1   The Local Government Debt Category Matrix Diagram

2.2 The status quo of local government debt

In the process of studying the current situation of local government debt, this paper is based on the data from the National Audit Office, the Ministry of Finance, and publicly available data. After integrated processing, this paper conducts a preliminary analysis of the current situation of local government debt in China from 2014 to 2017 from both scale and structure.

(1)Scale of local government debt

Table 1   Comparison of the Scale of Local Government Debt in China, 2014-2017 (In Billions of Yuan)

Year	Special Debt	General Obligation	Total Debt
2014	59801	94272	154073
2015	54949	99619	154568
2016	55244	98312	153556
2017	61384	103322	164706
Figure 2   Growth of Local Government Debt in 2014-2017 (In Billions of Yuan)

By the end of 2017, the scale of China's local government debt reached 164706 million yuan, of which the general debt was 103,332 billion yuan, accounting for a large proportion. First, from the analysis of total debt, the total local government debt in 2014-2017 stabilized at about RMB 1.6 trillion, and the overall trend is upward. The growth rate is stable. Second, from the analysis of debt growth rate, local government debt will increase from 2016 to 2017 faster; other years have not changed significantly.

All explained that China's local government debt changes have been relatively stable in recent years, and the debt risk is controllable.

Table 2   Comparisons of China's Local Government Debt and Gross Domestic Product (GDP), 2014-2017
(In Billions of Yuan)

Year	GDP	GDP Growth Rate	Total Debt	Debt Growth Rate
2014	636463	7.4%	154073	0.299%
2015	689052	6.9%	154568	0.321%
2016	744127	6.7%	153556	-0.0655%
2017	827122	6.9%	164706	0.72%

According to Table 2, from 2014 to 2017, the total amount of local government debt in China changed little and the rate of change was relatively stable, while GDP continued to grow, with a large growth rate, stable at around 7%. All these indicate that China's economy has ability to developed in the capacity of local government debt.
Figure 3   Comparison of Local Government Debt and GDP in 2014-2017 (In Billions of Yuan)

At the same time, growth rate of local government debt is much higher than GDP growth, this phenomenon is most evident in 2016, reflecting significant effectiveness in local government debt country limit management in 2016 (specific changes of trend is in Figure 3) .

According to the data shown in Table 3, China's local fiscal budget revenue has increased year by year from 2014 to 2017, with a stable growth rate of about 8%. Increases in local government debt were significantly reduced since that control of quota control in 2015. The growth rate of local government debt is obviously lower than the growth rate of local fiscal budget revenue. The overall scale of the debt risk is controllable, but the growth rate has a rising trend, which indicates that it is necessary to implement quota control and strengthen the supervision of local government debt.

Table 3   Comparison of Total Local Debt and Local Budget Income in 2014-2017 (In Billions of Yuan)

Year	Local Budgetary Revenue	Local Fiscal Budget Revenue Growth Rate	Total Local Government Debt	Local Government Debt Growth Rate
2014	140406	8.60%	154073	0.30%
2015	152249	8.40%	154568	0.32%
2016	146681	7.40%	153556	-0.07%
2017	156665	7.70%	164706	0.72%

(2)The structure of local government debt
Figure 4   A Bar Chart about the Structure of Local Government Debt in China, 2014-2017
(In Billions of Yuan)

According to the analysis of Figure 4, China's local governments generally have more general debts than special debts, more than half of the total debt balance. In 2017, for example, where local government debt accounted for 37 percent of that total debt, whereas the general debt ratio of up to 63 percent, the data is shown in Figure 5. All indicates that local government general debt contributed significantly to the total debt. In general, China's local government debt structure is stable from 2014 to 2017.
Figure 5   Pie Chart of Local Government Debt Structure in China in 2017

From 2014 to 2017, China's economy developed rapidly, but the level of inter-regional development was not balanced, leading to differences in the debt structure of regional governments. Many developed regions are mostly developed debt, with a large debt scale. And in less developed areas, more of the debt is guaranteed, such as building roads, schools and hospitals. The total debt is relatively small.

In conclusion, we have a larger and more substantial debt in our local government, but the growth is relatively stable, and the debt risk is controllable. The effect of national quota management on local government debt has been remarkable, and there is room for growth in the bear capacity of local government debt. Local government debt in China is given priority to with general obligation, regional structural differences need to be balanced.

3 Causes and Consequences of Local Government Debt

At present, the risk factors of local government debt are diverse, mainly including scale risk caused by the debt undertaken by local governments exceeding their fiscal revenue capacity, structural risk caused by unreasonable fiscal expenditure choices of local governments, efficiency risk caused by the low efficiency of local governments in the use of funds, and external risk caused by the transfer of debt from local governments to higher government institutions. In view of this, a causal diagram is used to analyze that origin and outbreak of local government debt risk.

3.1 Causes of local government debt risk

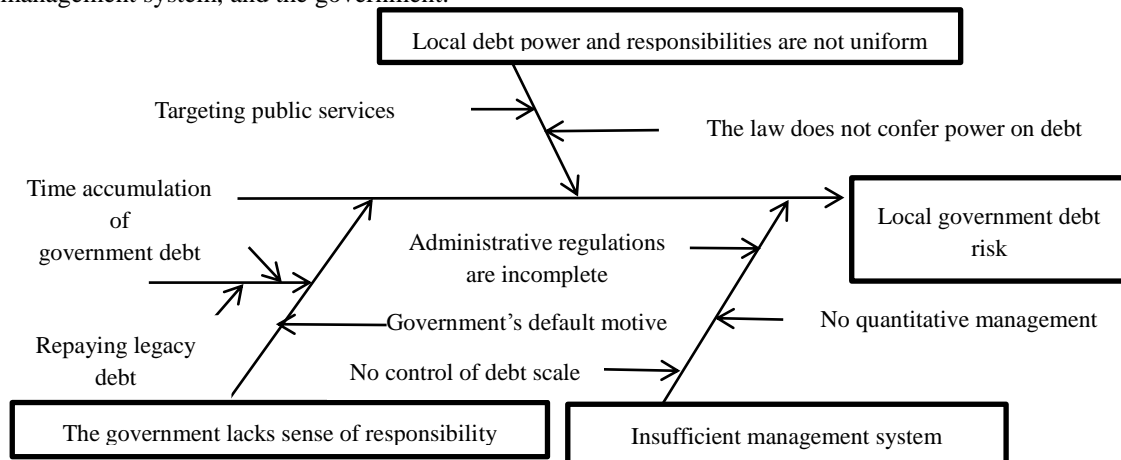
According to Figure 6, the risk of the local government's debt is mainly due to irrational growth and expansion of the debt motive, and this paper is a detailed analysis of the separation of authority, the management system, and the government.


Figure 6   Local Government Debt Risk

(1) The unified ownership and responsibility of local governments' liability

At present, local government liability has become a common phenomenon, and the government's exercise of employing liability has turned into a reasonable means of economic adjustment. However, in fact, China's laws do not entail local governments the power to practice liability. Local governments exercise their creditor's rights in the absence of unified rights. The rationality of government borrowing is its aim at public interests by offering the public service, thus to realize the public interests is the counterpart to the exercise of borrowing money, which is directly related to the repayment of the governmental debts. The lack of legal constraints and clear rights and obligations makes it impossible to guarantee the relevant interests of the current and future public service rights and responsibilities and makes it difficult to repay debts. Whether the rights and responsibilities of local government liability are unified determines whether public interests can be truly maintained and realized.

Take Sichuan province as an example. From 2008 to 2011, the province borrowed a lot of money to meet its fiscal targets, adding 4 trillion yuan of investment funds, 70.0% of which came from local government debt and government budget, causing a surge in local debt. After 2012, the government invested a lot of money to accelerate the construction of transportation facilities and the construction of new urbanization in the province, resulting in high debt. In 2016, the GDP growth rate of the province was 36.9%. Meanwhile, the local debt of the province was 781.00 billion yuan, of which 32.5% were contingent liabilities. The debt growth rate was 45%, far higher than the GDP growth rate of the same period.

(2) Imperfection of management system

The blind expansion of local government liability is due to the lack of a strict and sound debt issuance and repayment system. Therefore, we should improve the system of borrowing procedures, supervision and repayment, and standardize the formation and confine the expansion of local government liability in the cage of the former system. At the end of last century, the United States put forward measures to quantitatively manager state liability. That is, all state debt activity should be under control of a special institution strictly restricting the scales of debt through compulsory administrative standards and active management system, in order to impel government to meet its debt obligations.

In Sichuan province, for example, the total amount of local government debt due in 2017 is large, while short-term debt reaches 55.2%. Five-year and seven-year bonds account for 66.6% of total local government debt. As a result, short-term debt accounts for a large proportion of local government debt, and the repayment pressure is high.

(3) Lack of administrative sense of responsibility

As the debtor, from the point of government behavior, local government itself has the motivation to break the contract, especially when information mutuality is not achieved, the government as the main economic body blindly pursues the maximization of interests, which could lead to the expansion of liability. Many international theories suggest that the risk posed by the expansion of local government liability is largely due to "irresponsible debtors".

The accumulation of local debts over time has resulted in the current government departments having to repay part of the debts left over by the previous government in addition to the debts they borrowed, thus greatly increasing the financial pressure.

When the "irresponsible" become a kind of default rules, the government due to financial pressure has to "robbing Peter to pay Paul". In order to meet the demand of daily reasonable money, they borrowed huge amount of money and thus form excessive borrowing behaviors.

China's county-level local debt repayment consciousness is poor. Most county-level industries are mainly primary industries, and the financial income is small and unstable. At the same time, the county-level economic development require a large amount of capital, which results in the county-level government financial pressure, the rapid growth of local debt, and the increase of debt risk. Take Sichuan province as an example. In 2016, the county-level government debt of the province was 491.40 billion yuan, accounting for 62.0% of the total debt. In 2016, the growth rate of county-level debt in Sichuan province was 21.0%, far higher than the growth rate of 3.8% for municipal debt.

(4) Inefficiency of local government

The risks concerning local government debt structure and scale to a great extent are from the government inefficiency. Because of uneven distribution of fiscal spending and ambiguity of local fiscal system, local government leads a snub attitude on fiscal problems, and then governmental insolvency happens.

3.2 Consequences of local government liability risk

Local government liability is an important financial means for local government to adjust the

economy. If it grows in accordance with the normal growth, it is not harmful and does not pose a debt risk. Abnormal growth, however, if the government liability increases irregularly, it is not only a threat to the financial health in one region, it will also trigger a transmission mechanism: disruption of the state finance and financial order, and even the national economic operation system, leading nationwide economic crisis.

(1) Threaten local governmental finance

According to the results of National Government Debt Audit (National Audit Office, No.32 of 2013) of the national audit office, the total debt of local governments is relatively high, among which the liabilities for repayment account for a large proportion of local fiscal revenue. Nearly half of the 36 local governments surveyed have debt ratios of more than 100 per cent, and their delinquencies have continued to rise in recent years.

The debt ratio of local governments often exceeds the national warning line, which will enlarge the financial risk, amass the obligations of government, and finally affect the credibility of the government.

(2) Initiate financial risk

At present, local governments borrow mostly through investing and financing platforms and bank loans, which are relatively large. On this basis, local governments are often invisible guarantors. Due to the capital amount and capital circulation, these two methods of debt financing have great risks -- most financing platforms also have the problem of illegal capital absorption, and the funds are mainly circulated to the direction of public welfare projects.

This means that the credit risk of the platform company is transferred to the government as its credit risk and financial system risk. Failure to repay the debt at maturity will quickly lead to the formation of bad bank loans, which will be transformed into the crisis of the national financial system.

(3) Form social crisis

Under China's existing system, once local governments have debt repayment problems, their financial pressure will be transmitted to the central government and spread rapidly to the whole country. At present, our country is in the new period of socialist construction walking in the deep waters of socialist reform and having to overcome many difficulties, once the local governments increases income and cuts expenditure, it is bound to influence the results of governmental measures to the reform because of inadequacy of financial input, and even likely to intensify social contradictions, making it even harder to build a harmonious and stable economic and social environment.

(4) Reduce the credibility of local government

Local government liability management system is an imbalance of the assessment of administrative achievements and debt liability, the latter one is to an extent ignored. The abuse of administrative power to excise excessive liability, illegal financing behaviors by guaranteeing credibility can lead to the formation of an overly complex debt chain, making the debt unable to be paid. It not only affects the healthy development of local economy, but also affects the authority of the local government, which is extremely harmful to the government's social image.

(5) Influence the social liability environment

Local government debt scale once more turns bigger than financial income scale, will lead to an increasingly complex social liability chain, forming "triangle liability" phenomenon, as a result, social capital flow speed is reduced, efficiency of capital utilization turns low, which is not conducive to the development of social productive forces and purity the social environment of liability.

4 Prevention and Measures of Local Government Debt Risk

Based on the analysis of the causes and consequences of local government debt risks, the specific measures for risk prevention and resolution proposed in this paper are as follows.

(1) Clarify the right and responsibility relationship of local government debt

In view of the inconsistency of the local government's debts and responsibilities, the government must strengthen debt management, clarify the right and responsibility relationship of local government debt, and rationalize the division of powers. We should improve the fiscal and taxation system and clarify the respective debt responsibilities of the central and local governments. We're supposed to clean up and rectify the illegal financing platform, establish a modern enterprise system, improve corporate governance structure, and introduce high-quality specialized personnel to ensure that the financing platform operates scientifically, rationally, and regularly, and legally promote economic development.

(2) Strengthen the sense of debt responsibility of government officials

With regard to the problem of unsound management system, the government should strictly control the scale of debt and adopt mandatory regulations to restrict government liability. The government

should deal with officials' reform of the assessment mechanism, strengthen publicity and education, raise officials' awareness of responsibility, and establish a clear view of performance. We should establish and improve laws and regulations, improve the system of debt-relief personnel, and avoid unlawfully borrowing due to outstanding achievements. If recurrence of adverse consequences arising from illegal local borrowings occurs, administrative responsibility should be pursued in accordance with the law, and criminal responsibilities should be severely investigated.

Improve the debt supervision mechanism

(3) With the lack of awareness of local government responsibility, local governments should improve the debt supervision mechanism and increase the transparency of government debt information. The open and transparent government affairs will help control the scale of debt and effectively curb debt expansion. Appropriate information disclosure mechanisms can strengthen government responsibilities and constrain government debt behavior.

(4) Improve the budget management of local government

The government should improve local government budget management in response to the irrational local fiscal budget. Debt is incorporated into government budget management, so that the scale of borrowing is reasonably restricted under the budget system. This move can optimize the structure of the fiscal budget and allocate social resources as a whole, so that the scale of government debt can be controlled in the budget management system.

(5) Learn from the market economy

Under the market economy environment, the government should also introduce market mechanisms, establish a market environment conducive to the management of local government debt risks, draw on market economy related practices, introduce government debt credit ratings, reduce government financing capital, and protect creditor's benefits in the aim of reduce government debt risk.

5 Conclusion

The overall trend of the development of local government debt risk in China is stable and controllable. However, due to factors such as the inconsistency of local government debt obligations and the imperfect system, there are some hidden risks in the debt structure and other aspects. It is necessary to strengthen government debt management and improve the supervision mechanism, forming a system of local government debt risk early warning mechanisms. In the new era of socialist construction, combined with the new development of the socialist market economy, China now needs to establish a market environment for controlling local government debt risk and reducing the harm of risk.

Analysis of Influencing Factors of Reservoir Immigrants' Human Capital Accumulation: A Case of Three Gorges Reservoir Area

Xiang Caihong[1], He Jiajun[2]
1 School of Economics, Wuhan Donghu University, Wuhan, P.R.China, 430212
2 School of Management, Wuhan Institute of Technology, Wuhan, P.R.China, 430205
(E-mail: smileinlove@qq.com, hjj1618@163.com)

Abstract: Based on the survey data of the immigrants in the Three Gorges Reservoir area, this paper used the factor analysis method to find out the influence factors in the process of accumulating the immigrant human capital, which can be summarized as economic factors, system policy factors, resource endowments factors and educational level factors. Then, this paper used the grey correlation analysis to analyze the internal effects of these four factors on the accumulation of immigrant human capital. It is found that the influence of these four factors is from large to small, followed by economic factors, system policy factors, resource endowments factors and educational level factors. This research may guide the government to help the reservoir immigrant effectively.
Key words: Reservoir immigrants; Human capital accumulation; Factors; Structural analysis

1 Introduction

China is one of countries with the most reservoir projects and immigrants. However, numerous immigrants' livelihoods are damaged during immigration because of changes to their living conditions. As a consequence, many immigrant families are at risks of secondary poverty over again. From existing domestic literature, it may be known that immigrants have been really subject to secondary poverty after their resettlement in large reservoirs. In their survey on immigrants of the South-North Water Diversion Project, Hu Jing et al (Hu Jing et al, 2010) discovered that some of original human capitals malfunctioned after immigration, because the movement induced by external-force intervention impacts immigrants' original abilities to accumulate human capitals, and pointed out that their previous abilities became ineffective for alleviating poverty.Ginsburg et al (Ginsburg et al, 2016) pointed out that the development of immigrants 'skills can help to improve their mobility. Gautam (Gautam, 2017) considered the human resources as an important factor in the resistance of immigrant livelihoods.Liu Huicong (Liu Huicong, 2018) pointed out that the reconstruction of human capital is the key factor for the resettlement of reservoir immigrants.More and more existing literature has proven that human capital accumulation promotes regional economic development. Hence, it may be concluded that human capital accumulation plays important roles in family economy and regional economy of reservoir immigrants.

Based on survey data about the Three Gorges Dam, this paper explores the factors that exist in human capital accumulation of immigrants in the Three Gorges Dam and comparatively analyses the extent of impacts, in order to provide decision-making support for immigration-related departments to formulate policies for improving human capitals of immigrants.

2 Index Construction and Data Source

2.1 Index construction

On previous evaluations of human capital accumulation, selected indexes were about formal education, health status, vocational education and training as well as labour force migration. However, these indexes are not ideal representative factors that impact immigrants' accumulation of human capitals. Large surveys on reservoir immigrants show that immigrants are unenthusiastic about re-employment training, because their original human capitals malfunction after movement and there is a lack of employment opportunities. Furthermore, immigrant families' educational investments are structural and immigrants are also impacted by government support. Therefore, it is inadvisable to discuss index construction for factors affecting human capital accumulation of immigrants simply from these four perspectives. Instead, indexes are expected to be selected from deeper perspectives such as immigrants' endowment, financial conditions, governmental institutional support and educational conditions. In view of this, 21 indexes are chosen based on economic factors (income and consumption), policy factors and basic traits of immigrants.

2.2 Data sources

Data were collected from surveys on living and production conditions of immigrants in the Three Georges Dam over 8 years from 2004 to 2011. There were five types of respondents, including rural latter settled immigrants, urban immigrants occupying land, pure residents, corporate staff and employees of industri al and mining enterprises.

Table 1   Descriptions of Basic Variables

		Mean	SD
X1	Householder's Educational Attainment Illiterate = 1, primary school diploma = 2, middle school diploma = 3, high school diploma = 4, university diploma = 5	3.24	0.81
X2	Spouse's Educational Attainment Illiterate = 1, primary school diploma = 2, middle school diploma = 3, high school diploma = 4, university diploma = 5	2.92	0.92
X3	Educational Attainment of Member 1 Illiterate = 1, primary school diploma = 2, middle school diploma = 3, high school diploma = 4, university diploma = 5	3.29	1.23
X4	Educational Attainment of Member 2 Illiterate = 1, primary school diploma = 2, middle school diploma = 3, high school diploma = 4, university diploma = 5	2.17	1.81
X5	Householder's Age	3.01	0.69
X6	Spouse's Age	2.84	0.68
X7	Age of Member 1	2.15	0.55
X8	Age of Member 2	2.11	0.64
X9	Food Expenditures (RMB)	6,274.47	3,817.27
X10	Clothing Expenditures (RMB)	698.68	711.06
X11	Living Expenditures (RMB)	915.07	1,086.40
X12	Expenditures in Household Equipment/Articles and Services (RMB)	517.4	945.79
X13	Healthcare Expenditures (RMB)	1,319.64	3,365.71
X14	Transport and Communication Expenditures (RMB)	823.01	757.9
X15	Expenditures in Cultural, Educational & Recreational Articles and Services (RMB)	2,299.44	3,017.00
X16	Living Expenditures per Capita (RMB)	3,113.73	2,043.88
X17	Engel's Coefficient	0.59	0.34
X18	Per Capita Labour Income (RMB)	7,297.87	7,160.21
X19	Per Capita Net Income (RMB)	4,192.56	2,664.43
X20	Income from Government Transfer (RMB)	920.96	937.37
X21	Government Support (RMB)	3,529.93	3,773.74

3 On Factors Impacting Human Capital Accumulation of Immigrants

In this paper, indexes impacting human capitals of immigrant families are selected by principal component analysis. Then, several aspects that affect human capital accumulation of immigrant families are classified and summarized.

3.1 KMO and bartlett spherical tests

KMO and Bartlett spherical tests were performed on all effective data to confirm feasibility of factor analysis. The results are shown in Table 2.

Table 2   KMO and Bartlett Spherical Tests of Factor Variables

Kaiser-Meyer-Olkin Measures with Large Sample Size		0.61
Bartlett's Test of Sphericity	Approximate Chi-square	1,236.19
	df	210
	Sig.	0

KMO value is taken to be 0.610. According to standards of Kaiser who is a statistician, principal component analysis may be performed on these variables. Concomitant probability of Bartlett's test of sphericity is 0.000 and below the significance level (0.05), so null hypothesis of Bartlett's test of sphericity may be rejected. Correlations of variables are considered to eliminate variables that are not

highly related, and 21 indexes are reduced to 16. Five indexes, including X4 (educational attainment), X8 (age of Member 2), X11 (living expenditures, RMB), X12 (expenditures in family equipment/articles and services, RMB) and X13 (healthcare expenditures, RMB), are eliminated. KMO and Bartlett spherical tests are performed over again. In these tests, the value of KMO is taken to be 0.673. According to the standards of Kaiser, principal component analysis may be performed on these variables.

3.2 Related Matrix Eigenvalues and Cumulative Contribution Rate

After maximum orthogonal rotation of raw data through principal component extraction, 6 principal components with an eigenvalue above 1 are extracted and items with a factor loading above 0.4 are selected. The percentage of total variance explained is 79.332%, which suggests that all factors may be explained relatively well. The construct validity of samples is acceptable. The variance of principal components is always above 0.4 whichever item is. This indicates that most variations of observed variables are explained by principal components.

Table 3   Principal Components with a Post-Rotation Eigenvalue above 1 and Variance Contribution Rate

Principal Components	Eigenvalue	Variance Contribution Rate(%)	Cumulative Variance Contribution Rate(%)
1	4.478	27.988	27.988
2	2.225	13.908	41.895
3	1.857	11.604	53.499
4	1.592	9.951	63.45
5	1.414	8.838	72.288
6	1.127	7.044	79.332

3.3 Factor loading matrix

By analysing the common factor loading matrix of factors impacting human capitals of sampled immigrant families, the first four extracted principal components were found to have evident composition, whereas the composition of the latter two was not striking. Therefore, only the former four principal components were selected in this study and their cumulative variance contribution rate was 63.45%.

3.4 Scores of common factors

The calculations suggested that the variables with relatively material impacts upon the principal component F1 included X7 (0.719), X8 (0.691), X9 (0.751), X10 (0.593), X11 (0.810), X12 (-0.479), X13 (0.582) and X14 (0.705). Above factors are associated those for evaluating income, consumption and economic conditions, so the principal component F1 is categorized as "economic factor". The variables with relatively significant impacts upon the principal component F2 include X15 (0.676) and X16 (0.705). In view that both transfer income and project support are governmental policy support for employment and livelihoods of immigrants, the principal component F2 is classified as an "institutional policy factor". The variables with relatively considerable impacts upon the principal component F3 include X4 (0.588), X5 (0.567) and X6 (0.556). Hence, this principal component may be categorized as an "endowment factor". The variables that impact the principal component F4 relatively significantly include X1 (0.444), X2 (0.509) and X3 (0.444), so this principal component may be categorized as a "factor about educational conditions".

4 Structural Analysis of Factors Impacting Immigrants' Human Capital Accumulation

4.1 Analysis of grey relations and factors impacting human capital accumulation of immigrants

Generally, economy, institutional policies, endowment and educational attainment are included in immigrant families' systems for human capital accumulation. These systems vary with the factors, thus composing a dynamic system. In these systems, the extent to which factors are interconnected with immigrant families' systems for human capital accumulation is unknown, and incompletely identified in some cases, so a grey system forms. In this study, grey relational analysis is performed as a basic approach to structural analysis of the factors. The extent of interconnections is determined by corresponding formulas to measure contributions of these factors to immigrant families' human capital accumulation and find out intrinsic relationships of the factors.

4.2 Analysis of calculations

4.2.1 Analysis of four factors and results of grey relational analysis on human capital accumulation

Among the four factors, human capital accumulation of reservoir immigrants is impacted most significantly by economy, followed by educational conditions, institutional policies and endowment successively. The results suggest that China's national strategies for economic development have exerted significant impacts upon urban and rural human capital accumulation since the nineties. They also show that after immigration, the immigrant families' human capital accumulation is impacted most immediately by the level of regional economic development at reservoirs. Immigrant families under better financial conditions may invest more in education, health preservation and skills of their family members. Furthermore, they may increase their incomes through familial business activities, where they constantly increase their special human capital accumulation.

4.2.2 Analysis results of grey relations between sub factors and human capital accumulation

In terms of economy, relations are as follows: The human capital accumulation is impacted significantly by families' income and expenditure. The impacts of expenditures in clothing, transport and communications are the most significant, whereas the degree of impacts is always not below 0.97 whichever the income and expenditure. This reflects that immigrant families' human capital accumulation may be improved by increasing human capital investments as long as income increases.

The relations of institutional policies suggest that government plays important roles in increasing human capitals of immigrant families. Since 2007, governmental work has focused on sustainable livelihoods of immigrants. While improving infrastructure, governments have made unremitting efforts to reinforce the improvement of immigrants' livelihoods by different preferential policies. According to views about sustainable development of immigrants' livelihoods, governments' transfer payment and other policy support are not only helpful for increasing net income of immigrant families, but also enhance stocks of human and social capitals with abundant material capitals.

Based on relationships of educational conditions, two conclusions may be reached as follows: On one hand, rural families are more inclined to place hope upon male labourers owing to their traditional ideas. If possible, they tend to increase their human capital investments through male labourers. On the other hand, age is a basis of reference for families to allocate human capitals to family members. Young people hope that they can cultivate skills for earning a living by receiving more training, while the aged prefer health investments.

As regards endowment, relationships suggest that human capitals of immigrant families are mainly from the investments in formal education, training and health of the young generation and families. Apart from taking care of their families, householders' spouses can also engage in business activities of families since governments offer business and employment opportunities to families in immigration projects. For instance, there are stores in residential areas after immigration. Therefore, householders' spouses ought to increase their human capitals as well.

5 Conclusion

The research suggests that economy, institutional policies, endowment and educational attainment impacts human capital accumulation of immigrants. Among these four factors, economy imposes the most significant impacts. This reveals that only if immigrant families have certain financial strengths can they accumulate more human capitals effectively. Secondly, it may be known from institutional policies that at present, government still plays important roles in economic life of reservoir immigrants. To increase income of immigrant families, great investments and support from government departments are also needed. Thirdly, research findings on educational conditions suggest that immigrant families' investments in education have relatively significant impacts upon human capital accumulation. In terms of endowment, age is found to be an important factor that impacts human capital accumulation of immigrants.

Empirical Analysis of the Profitability of Chinese Listed Commercial Banks under the New Economic Normality

Yuan Ruocan, Wan Youqing
School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: 805914786@qq.com, w13308641188@126.com)

Abstract: Based on the panel data of China's 16 listed banks from 2011 to 2017, this paper empirically investigates the relationship between the bank's income structure and profitability with the regression model. The results show that the bank profitability has the positive correlation with net interest margin, non-interest income ratio, and fee and commission income ratio; the efficient control of cost-to-income ratio and the optimization of the bank size are helpful to improve the bank profitability; the risk indices show the significantly negative correlation with the bank profitability; the decline in GDP growth to a certain extent has a negative impact on the bank profitability. The results provide references for optimizing the income structure of commercial banks under the new economic normality.

Key words: New economic normality; Bank profitability; Income structure; Non-interest income; Empirical analysis

1 Introduction

After 2011, the macroeconomic growth rate shows a continuous downward trend. Changes from the supply side and the demand side together shapes the "new normal" of China's economic development; its main characteristics can be summarized as "high-speed, superior structure, new momentum, more challenges." (Qi Jianguo, 2015)Because of interest rate liberalization and financial disintermediation, the traditional deposit and loan business of commercial banks have limited spaces. It is important for commercial banks to integrate various industry resources such as insurance, funds, securities, leasing, and trusts during the window of business transformation. Comprehensive operationsbecome the important support for commercial banks to carry out financial innovation, optimize income structure, and increase the return rate of risky assets. (Chen Siqing, 2015)

Chiorazzo et al. believe that the diversification of the income structure significantly increases the returns of large banks, and its size is more important than the source of non-interest income. (Chiorazzo, 2008) Lepetit et al. argue that relying too much on non-interest income reduces the bank's earnings and leads to the volatility of net operating income growth.(Lepetit, 2008) Li L. et al. also show that the intermediary business income has greater volatility and periodicity than the traditional business income and is vulnerable to be impacted. (Li L., 2013)An increase in the degree of bank diversification within non-traditional bank activities leads to an increase in bank liquidity creation. (Xiaohui Hou, 2018) The pre-crisis diversification discount is considerably smaller in a robust regression, which in part is driven by banks with a large share of non-interest income. (Nicolas Guerry, 2017) The short-term changes in non-interest income have important influence on the short-term fluctuations in commercial bank operating performance. (Fang Hong, 2012) Wang Shuman et al. believes that the profitability of banks is the result of the comprehensive effects of net interest margin, non-interest income, and cost-to-income ratio, in which the impact of non-interest income on differences in bank profitability is increasingly important. (Wang Shuman, 2013) The literature (Chen Yihong, 2015; Wang Siwei, 2015; Peng Mingxue, 2016) show that the increase in the proportion of non-interest income helps to improve the bank's operating performance, and the diversified profit model and income structure are the focus of future strategic transformation of commercial banks. Limei Sun et al. argue that there is a general negative correlation between the noninterest income ratio and performance of commercial banks. (Limei Sun, 2017)

Based on the panel data of 16 listed commercial banks from 2011 to 2017, this paper models the profitability of commercial banks and analyzes the influencing factors to provide reference for optimizing the income structure of commercial banks in the new economy normal.

2 Data, Variable Definitions and Descriptive Statistics

2.1 Data sample

At present, there are 26 listed commercial banks in China. Based on the Integrity and reliability of data, this paper chooses 16 of them in 3 categories as the research objects, which are state-owned

commercial banks including Bank of China, Industrial and Commercial Bank of China, China Construction Bank, Agricultural Bank of China, and Bank of Communications; joint-equity commercial banks including Ping An Bank, China Merchants Bank, China Everbright Bank, China CITIC Bank, Huaxia Bank, China Minsheng Bank, Industrial Bank, and Shanghai Pudong Development Bank; and city commercial banks including Beijing Bank, Nanjing Bank and Ningbo Bank. Data samples come from the annual panel data released by the 16 commercial banks from 2011 to 2017.

2.2 Variable definitions and descriptive statistics

(1) Dependent variables

The profitability of commercial bank is defined as the ability to use its own assets to generate revenue. Generally, the profitability of commercial bank can be measured by the indices of ROA (Return on Assets) and ROE (Return on Equity). The larger the two indices of ROA and ROE, the stronger the profitability of the commercial banks. According to the reference(De Young, 2004) and with consideration of data availability and reliability, this paper uses ROE as dependent variable to measure the bank profitability, which directly reports the bank's competitive strength and development capability.

(2) Independent variables

Commercial bank revenue consists of interest income and non-interest income, of which interest income has been the main source of revenue. With interest rate liberalization, it is inevitable for commercial banks to develop the non-interest businesses, including the intermediate businesses such as fees and commission income typically.

This paper selects the net interest margin (NIM) as the interest income, the non-interest income ratio (NIIR) as the non-interest income, and the fee and commission income ratio (COM) as the intermediate business income to measure the bank income structure and mirror the structure's influence.

(3) Control variables

To eliminate the influences of other factors on independent variables, several control variables are selected to ensure the accuracy of the investigated results.

The bank size, which can be represented with total assets logarithm (ASSET) to reduce the volatility of the original sample, has an impact on the bank profitability. The cost-to-income ratio (COST) reflects the bank's operating costs and is an important measure of bank fee control ability and profitability. Asset quality is a measure of effective use of credit assets and risk resilience, which can be explained with the non-performing loan rate (NPLR), the capital adequacy ratio (CAR), and the loan-to-deposit ratio (LDR). The speed of national economic growth will inevitably affect the development of banks, which is measured with gross domestic product(GDP).

The definitions of all the variables with the data descriptive statistics used in this paper are shown in Table 1.

Table 1   Variable Definitions and Descriptive Statistics

Variable Name	Variable	Min.	Max.	Mean	Standard Deviation
Return on Equity	ROE	.1140	.2665	.1796	.0333
Net Interest Margin	NIM	.0000	.0348	.0240	.0043
Non-Interest Income Ratio	NIIR	.0944	.4030	.2345	.0773
Fee and Commission Income Ratio	COM	.0778	.3368	.1931	.0595
Total Assets Logarithm	ASSET	.2159	.4253	.3040	.0431
Cost-to-Income Ratio	COST	10.9718	13.3141	12.3873	.5638
Non-Performing Loan Rate	NPLR	.0038	.0239	.0117	.0043
Capital Adequacy Ratio	CAR	.0988	.1565	.1254	.0140
Loan-to-Deposit Ratio	LDR	.0000	1.0516	.7045	.1326
Gross Domestic Product	GDP	.0669	.0954	.0756	.0091

3 Regression Model and Empirical Analysis

3.1 Regression model

To investigate the relationship between the income structure and profitability of commercial banks, a panel data model is used for regression. With the analysis of the correlation between the index variables based on the data samples, the results show that NIIR and COM are closely related. Therefore, NIIR and COM are considered separately to examine the impacts of the non-interest income and the

intermediate business income on the bank profitability. The two multiple linear regression models are established as follows:

$$ROE_{it}=\beta_0+\beta_1 NIM_{it}+\beta_2 NIIR_{it}+\beta_3 COST_{it}+\beta_4 ASSET_{it}+\beta_5 NPLR_{it}+\beta_6 CAR_{it}+\beta_7 LDR_{it}+\beta_8 GDP_{it}+\varepsilon_{it} \qquad (1)$$

$$ROE_{it}=\beta_0+\beta_1 NIM_{it}+\beta_2 COM_{it}+\beta_3 COST_{it}+\beta_4 ASSET_{it}+\beta_5 NPLR_{it}+\beta_6 CAR_{it}+\beta_7 LDR_{it}+\beta_8 GDP_{it}+\varepsilon_{it} \qquad (2)$$

where i denotes a commercial bank, t denotes time, β_0 denotes a constant term, $\beta_1 \sim \beta_7$ denotes a regression coefficient, ε_{it} denotes a random error term, and ROE_{it} denotes a return on equity of the tth period of the ith listed commercial bank. The others are similar.

3.2 Regression results

All data samples from 2011 to 2017 are divided into 4 groups, which are all banks' sample, state-owned banks' sample, joint-equity banks' sample, and city commercial banks' sample. And based on the 4 group samples, 8 regression models of model (1) and (2) are established by SPSS software. The regression results are shown in Table 2 and Table 3.

3.3 Regression model analysis

The regression results from Table 2 and Table 3 show that:

(1) The R^2 of all regression models exceed 0.7, indicating that the overall model fitting degree are relatively high, and the independent and control variables considered have significant influences on the dependent variables with the same directions and significances. The regression models are stable.

Table 2　Regression Results with NIIR

R^2	0.741		0.947		0.827		0.858	
Adjusted R^2	0.720		0.931		0.797		0.763	
Sig.	0.000		0.000		0.000		0.000	

(2) The net interest margin, non-interest income ratio, fee and commission income ratio, and bank size are positively correlated with bank profitability. City commercial banks' non-interest income ratio and fee and commission income ratio have negative regression coefficients, which shows that the

growth rate of these two financial indicators do not make up for the decline in interest income. The non-performing loan rate, capital adequacy ratio, and loan-to-deposit ratio are negatively correlated with bank profitability. The cost-to-income ratio is significantly positively correlated with city commercial banks, which shows the better cost-control than other category banks. GDP is positively related to state-owned banks and negatively correlated with joint-stock banks and city commercial banks, indicating that GDP has negative impacts on the bank profitability as the macroeconomic growth rate drops to a certain extent.

4 Conclusion

According to the regression model, the following conclusions can be drawn:

(1) The largest regression coefficient of NIM shows that the interest income is still the main income source but is decreasing year by year. The non-interest income and fee and commission income are increasingly important to bank profitability. Therefore, commercial banks must adjust the income structure and expand the scale of non-interest business, especially the intermediate business.

(2) Commercial banks must improve management level to control costs as diversified business expanded. At the same time, the optimal size is necessary to promote the profitability.

(3) The promotion of profitability must base on the controllable risks. The non-performing loan ratio, capital adequacy ratio and loan-to-deposit ratio have negative impacts on profitability, especially the non-performing loan ratio and capital adequacy ratio. The robust operations and sustainable developments are available with the low bad loans as possible and the appropriate capital adequacy ratio and loan-to-deposit ratio.

Research on Crowdfunding and the Mining Model for Youth Entrepreneurial Risk Indicator Based on Co-word Analysis

Liu Yuqing, Chen Wenqi, Jiang Yao
School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: 403834825@qq.com, 735438451@qq.com, 834559890@qq.com)

Abstract: Nowadays, the integration of internet crowdfunding and youth entrepreneurship has become the trend of the times. And it brings unlimited new opportunities to the social economy. But at the same time, the risk of the organic combination of the two is still severe. Based on co-word analysis, this paper explores the integration model of internet crowdfunding and youth entrepreneurship, analyzes and summarizes the main reasons for the poor integration of internet crowdfunding and youth innovation and entrepreneurship. Meanwhile it uses cluster analysis and other research methods for inspection and evaluation. The result shows that the four risk indicators of "information richness", "amount of financing", "industry sector" and "financial condition" have a great impact on crowdfunding youth entrepreneurship, and they need to be taken seriously in project setting and development.
Key words: Internet crowdfunding; Youth; Innovation and entrepreneurship; Risk indicators; Co-word analysis

1 Introduction

Crowdfunding is an innovation of traditional financing mode based on the development of Internet technology. And it provides new financing channels and marketing tools for individual entrepreneurs and start-ups. As an important part of the popular entrepreneurship trend, youth entrepreneurship has attracted a lot of attention, but the success rate is very low.

As China's Internet crowdfunding market is still at an exploratory stage, there is no strict screening system. "Investors and financiers" in any corner of the world can participate in this platform. This leads to various risks such as uneven crowdfunding projects, financial opacity and lack of third-party supervision. In addition, there are many examples of failures in crowdfunding project. Therefore, how to evaluate and prevent the risk of crowdfunding for college entrepreneurs is particularly important and urgent.

At present, the implementation of the national development strategy of "Internet +" is rapidly expanding the boundaries of various industries. Crowdfunding is expected to become a power source to support popular innovation and entrepreneurship (Chen Yujie, 2015). At present, the classical models of entrepreneurial risk mainly include theoretical models of entrepreneurial potential (Atherton, Krueger, and Brazeal, 2004), entrepreneurial propensity assessment model, entrepreneur quotient model (Nortwestem Mutual Life Insurance, 1985), and entrepreneurial quality assessment, Grounded Model (Zhao Yuxiang, 2016), etc., also contains many scholars' qualitative indicators and theories for various fields and groups.

Based on the perspective of crowdfunding participation and operation, most scholars focus on the key factors that affects the success rate of crowdfunding models. At present, there are still blind spots in the research on the crowdfunding model of college students' independent entrepreneurship at home and abroad. Whether from the characteristics of university students' entrepreneurial team, the characteristics of university students' group or from the characteristics and scale of university students' entrepreneurial projects, the financing channels of college students' entrepreneurship are quite different from those of small and medium-sized enterprises and non-profit organizations. Therefore, in this paper, the entrepreneurial groups of college students are chosen for research. A quantitative analysis of the innovation and entrepreneurship of young people under the Internet crowdfunding from 2013 to 2018 is conducted in this research. The conclusions of the study can explain the successful laws of youth innovation and entrepreneurship and reflect the characteristics and trends of youth innovation and entrepreneurship under internet finance.

2 The Word Frequency Statistics

This paper mainly uses co-word analysis and cluster analysis methods to research the risk indicator of youth entrepreneurship that is under the crowdfunding model. Co-word analysis can count the times that a group of keywords appears in one literature, to find out the close relationship between these words.

On the basis of the statistics of co-word frequency, clustering analysis aggregates the topic words that are close together to form different groups. Each group reflects the specific focus of literature in a certain period of time. And then, we analyzed the structural changes of the disciplines and themes that represented by these words.

In this study, 3-4 key words were identified from each literature. The key words with high frequency were found through word frequency statistics, and the co-word matrix of high frequency key words in each phase was established, then, on the basis of the co-word matrix, using SPSS 21.0 for clustering analysis, and the word clusters of the co-words were displayed.

Table 1   The High-frequency Keywords of Crowdfunding and Youth Innovation and Entrepreneurship

Keywords	Word frequency	Keywords	Word frequency	Keywords	Word frequency
Project novelty	62	Equity structure	31	Credit investigation	62
Sense of leadership	27	Number of followers	47	Target amount	47
Information richness	255	Industry sector	131	Team cohesiveness	71
Transparency of financial information	43	Returning rate of project	31	consciousness of risk prevention	368
Market requirement	144	Amount of financing	176	Number of participants	88

Table 2   The High-frequency Keywords Dissimilarity Matrixes of Crowdfunding and Youth Innovation and Entrepreneurship (Partial)

	Project novelty	Sense of leadership	Information richness	Market requirement	Equity structure	Number of followers	Industry sector	Returning rate of project
Project novelty	.000	.528	.507	.422	.864	.770	.880	.228
Sense of leadership	.528	.000	.604	.556	.792	.798	.857	.769
Information richness	.507	.604	.000	.731	.935	.836	.498	.986
Market requirement	.422	.556	.731	.000	.907	.495	.286	.765
Equity structure	.864	.792	.935	.907	.000	.739	.834	.116
Number of followers	.770	.798	.836	.495	.739	.000	.781	.724
Industry sector	.880	.857	.498	.286	.834	.781	.000	.949
Returning rate of project	.228	.769	.986	.765	.116	.724	.949	.000
Team cohesiveness	.706	.665	.917	.474	.884	.576	.740	.566
consciousness of risk prevention	.811	.894	.870	.529	.979	.722	.609	.764
Number of participants	.697	.884	.846	.751	.778	.521	.519	.430

3 The Clustering Model and Analysis of High Frequency Keywords

3.1 Clustering analysis

This paper systematically analyzes high-frequency keyword dissimilarity matrixes using SPSS19.0. The ward clustering method, Phi square metrics counted, and Z score standardization was selected. The final clustering results are shown in the following figure. According to the figure, the researches about crowdfunding and youth innovation and entrepreneurship can be divided into four groups in the recent four years, namely as followed, financial information and equity structure; project attention-degree and financing needs; market conditions and team quality; project value and informatization. There are many factors involved in the project attention-degree and the market. Financial profitability as a separate category is also a very important factor.
Figure 1   The Tree Diagram of Clustering Results for High-frequency Keywords

3.2 Multidimensional scaling analysis of high frequency keywords

Multi-dimensional scaling analysis attempts to find data structures by measuring or observing the distance between individuals. The purpose of the analysis is to reflect the distances between individuals as much as possible by two-dimensional or three-dimensional spatial distances. In this way, we can objectively reflect similarity relationship between individuals. Using the multi-dimensional scale analysis of SPSS, two-dimensional scale analysis of dissimilar matrices of high-frequency related words was performed to obtain visualization results, as shown in Figure 2.

Taking X=0.8 and Y=0 as the coordinate axis, we can see that the "information richness", "financing amount" and "industry sector" are relatively far away from other indicators. There are great differences, which can be used as the core indicators of risk judgment. They have an important position in project evaluation. The aggregation located in the two or three quadrants are highly similar, with the financial condition of the project value as the core individual representation. It can be seen that the external factors such as market factors and financing amount play a more prominent role under the current pattern of crowdfunding and entrepreneurship, while the role of project features seems to be relatively weak. It is only necessary to focus on information richness.
Figure 2   The Results Map of Multi-Dimensional Scaling Analysis

4 Conclusion

In this paper, by searching for related papers about crowdfunding in recent five years, high-frequency keywords co-word matrices are formed by using high-frequency keywords as analysis samples, and analysis is conducted by using algorithmic classification tests and multi-dimensional scaling analysis and strategic coordinates and other methods. This paper summarizes four research topics and analyzes them one by one, to verify the key points of innovation and entrepreneurship of young people under the current Internet crowdfunding. The study findings were as follows:

(1) Fully reflect the richness of project information. (2) The financial situation and the amount of financing are still critical. Internet crowdfunding plays the role of investment beneficiary, and it is still very concerned about the financial expectations of startup projects such as profitability. With a reasonable allocation of equity, a substantial returning rate of the project can help achieve the finance amount really expected. (3) The consciousness of risk prevention is an important foundation for the development of the entire project. Projects with high-risk consciousness and strong team cohesiveness often persist longer. (4) Industry selection and market requirement play a decisive role. In crowdfunding and entrepreneurship, market requirement guides and selects projects, and industry trends determine the project development prospect.

Therefore, relevant domestic scholars should strengthen the application of big data in risk control of young people's innovation and entrepreneurship under Internet crowd-funding, combine with actual cases, guide the benefit maximization of crowdfunding innovation and entrepreneurship, and promote the deepening of the reform of the science and technology system further.

Capital Allocation Methods in Financial Institutions: A Review and Comparison

Han Yan
Department of Statistics, London School of Economics and Political Science, London, the U.K.
(Email: hanyan15@yahoo.com)

Abstract: Capital allocation plays a significant role in risk measurement for many financial institutions. The major concept behind the capital allocation is to allocate an adequate amount of economic capital to internal business units or portfolio elements, where the allocated risk capital is used to prevent unexpected losses (Ita, 2017). The amount of economic capital that is used to absorb potential losses of the company is determined by different risk measures, such as Value at Risk and Expected Shortfall. Since the allocated risk capital is thought to be a "cost" of an entity, it is important for financial institutions to allocate the capital in an efficient way for competition purpose (Denault, 2001). The project mainly examines the commonly used allocation methods with two risk different measures *Value at Risk* and *Expected Shortfall*, where the real financial data are employed. In the empirical study conducted in the paper, among all the methods, the allocated risk capital determined by the CAS allocation is the most stable one, while examine the stability of the resulted daily risk capital using the realized variance. Therefore, it can be concluded that the CAS allocation could be suggested for practical applications for financial institutions.
Key words: Capital allocation; Value at Risk; Expected shortfall; Euler method; CAS allocation

1 Introduction

Capital allocation plays an important role in risk measurement and assessment for many financial institutions. The allocated capital serves as the foundation in evaluating the risk-adjusted performance of business units. The major idea behind capital allocation is to allocate an adequate amount of economic capital to internal business units or portfolio elements, where the attributed capital is used to absorb unexpected losses (Ita, 2017). After the financial crisis in 2008, financial institutions have paid additional attention to access the risk-adjusted performance of internal business units, and the capital allocation framework is applied. In addition, the regulatory framework also requires corporations to quantify their total risk. Capital allocation rules allow large financial institutions, such as banks, to monitor the use of capitals and to evaluate risk-adjusted performance. As the the economic capital needed is calculated for each sub-unit to improve the efficiency of the allocation, it becomes possible for one to evaluate different parts of the portfolio and business lines (Holden, 2008). The applications of the capital allocation also include allowing financial institutions to better understand the contribution of different business lines to the economic capital, performing performance measurement, and it is also applied in strategic decision making process (Balog, 2017). The amount of riskless investments a firm holds and uses as an insurance against the uncertainty of the portfolio's net worth is named as risk capital by Denault (Denault, 2001).It is important for financial institutions to allocate the capital in an efficient way for competition purpose (Ita, 2017). Capital allocation provides a way for businesses and companies to determine the amount of economics capital required for different processes or divisions. However, the risk capital is thought to be a cost of a company because it is actually money instruments with extremely low risk and low return (Denault, 2001); therefore, it is important for companies to allocate such burden in an efficient way.

The amount of economic capital that is used to absorb potential losses of the company is determined by different risk measures, such as Value at Risk (*VaR*) and Expected Shortfall(*ES*). *VaR* is a risk measure which expresses the amount of economical capital necessary to ensure the probability, for a default is less than a certain confidence interval. According to McNeil, Fret and Embrechts (McNeil, Fret and Embrechts, 2015), one could interpret *VaR* as the "maximum loss which is not exceeded with a given high probability". *ES* is defined as the average of *VaRs* of portfolio-wide profit/loss at confident level α and higher (McNeil, Frey and Embrechts, 2015).According to Artzner, Delbaen, Eber and Heath (Artzner, Delbaen, Eber and Heath, 1999), a coherent risk measure should satisfy the properties including sub-additivity, monotonicity, positive homogeneity and translation invariance. Value at Risk (*VaR*) is one of the most commonly used risk measure, but it is not a coherent risk measure as it violates the criterion of sub-additivity (Balog, 2017). Nowadays, the trend is to use *ES* instead of *VaR* in risk measurement, since*ES* is a coherent risk measure (Balog et al, 2017).

Similar to risk measure, an allocation principle is said to be coherent if it satisfies the requirement

of certain properties. Denault (Denault, 2001) stated in the paper *Coherent Allocation of Risk Capital* that an allocation principle is coherent if it satisfies the requirements of no undercut (core compatibility), symmetry and riskless allocation. In addition, he proved that Aumann-Sharplay value is a coherent allocation principal while a coherent risk measure (Expected Shortfall) is used (Denault, 2001). Tasche (Tasche, 2008) discussed and presented two desirable properties of an allocation principle, which include full allocation and RORAC-compatibility. According to Denault (Denault, 2001), only the Euler principle (Aumann-Shapley value) with coherent risk measure (e.g. Expected Shortfall) meets all three requirements to be a coherent allocation method and RORAC compatible.

According to Kalkbrener (Kalkbrener, 2005), capital allocation enables the application of allocation of risk measures in evaluating performance and managing portfolio. In the paper *Wang's capital allocation formula for elliptically contoured % distributions* (Valdez and Chernih, 2003), the authors state that risk allocation not only set the risk limited but also allow one to better understand the risk bearing ability of insurance companies. In addition, Homburg and Scherpereel (Homburg and Scherpereel, 2008) states that the allocation method can be used to access the performance measure of organizations with divisions. What's more, Kim and Hardy (Kim and Hardy, 2009) studied how to allocate capital among business lines, and they also discussed about the application of capital allocation in performance evaluation and product pricing.

The main goal of this paper is to study and analyze the allocation methods (including marginal method, Shapley method, Euler principle and CAS allocation) with the two risk measure Value at Risk (*VaR*) and Expected Shortfall (*ES*) using the real financial data. In fact, there is a paucity of literature in using the real financial data to study the existing methods, people tend to use the simulation data for their study instead, (Balog, et, al., 2017). Moreover, there is few study that compare the CAS allocation with other existing methods, since the CAS allocation is a relatively new allocation method. This paper tried to fill the gap in some degree, since the real financial data is used to study the behavioral of the allocation methods with the two different risk measures.

2 Data and Algorithms

2.1 Data

For the empirical analysis, a portfolio with one unit of each stock index is constructed: DAX (German stock index), Standard & Poor's 500 (America stock index), NASDAQ (America stock index for technology stocks), Hang Seng (Hong Kong stock index). Suppose the quantity of each stock index does not change (i.e. always one unit) during the period of study, which means the overall portfolio value changes every day as the price of the stock index in portfolio changes. The indices prices are imported from the Yahoo Finance and the historical foreign exchange rates for currencies versus the US dollar is from Federal Reserve.

The daily stock index prices of the four indices are converted to the US dollar. And only the dates where all four stock indices have transaction are chosen for the analysis. The data is taken from 03/01/2001 to 30/12/2016, which would allow us to study the performance of the allocation methods during the 2008 global financial crisis. The daily portfolio-wide loss/profit is calculated as the following:

$$L_{t+1}^P = (P_{t+1}^P - P_t^P)$$

where the portfolio value $P_t^P = P_t^{DAX} + P_t^{SP500} + P_t^{NASDAQ} + P_t^{HangSeng}$

2.2 Algorithms

The daily risk capital allocation of each stock in the portfolio is calculated using the moving window technique. And the window size D is set to be 250, which is the number of the trading days in a year. The daily allocation of day T is then calculated using the data ends at day T and includes 250 data points before the day T. Two risk measures *Expected Shortfall(ES)* and *Value-at-Risk(VaR)* that are both homogeneous of degree 1 are used and compared in the analysis. As was mentioned in the previous section, *VaR* of loss distribution L is the q_α of L, and the *ES* is effectively *VaR* at level α and higher. For the empirical analysis in this paper, the value of α is set to be 0.99. The following sub-sections presents the mathematical formulas used for empirical analysis the methods.

2.2.1 Marginal method

The motivation behind the marginal method is to allocate risk capital based on the marginal effect of the ith component to the total portfolio risk (El Gharib et al., 2014). The method allocates the joint risk capital to the sub-portfolio proportional to the individual's marginal risk. Different from the activity based method, the marginal method considers the risk contribution of the ith subunit to the whole

portfolio by calculating the difference between the portfolio risk with and without the ith component. The following mathematical equation is the formula that is used to calculate the daily risk allocation of the ith stock $\rho\left(L_t^i\middle|L_t^P\right)$ in the constructed portfolio on day t using the marginal method, where *VaR* is the risk measure ρ:

$$VaR_t(L_i|L_P) = \frac{quantile_\alpha(L_t^P) - quantile_\alpha(L_t^{P\setminus i})}{\sum_{j\in N}(quantile_\alpha(L_t^P) - quantile_\alpha(L_t^{P\setminus j}))} quantile_\alpha(L_t^P)$$

where $t=T\text{-}D+1,\dots,T$, L_t^P represents the loss of the overall portfolio from day $t-D+1$ to day t.

The formula that is used for daily allocation becomes the following while using *ES* as the risk measure:

$$ES_t(L_i|L_P) = \frac{quantile_\alpha(L_t^P) - quantile_\alpha(L_t^{P\setminus i})}{\sum_{j\in P}(\mathbb{E}[L_t^P|L_t^P \geq VaR_\alpha(L_t^P)] - \mathbb{E}[L_t^{P\setminus j} \geq VaR_\alpha\left(L_t^{P\setminus j}\right)])} quantile_\alpha(L_t^P)$$

where $t=T\text{-}D+1,\dots,T$, $\mathbb{E}[L_t^P|L_t^P \geq VaR_\alpha(L_t^P)]$ and $\mathbb{E}[L_t^{P\setminus j} \geq VaR_\alpha(L_t^{P\setminus j})]$ represents the *ES* for the loss of the overall portfolio L_P and the portfolio excluding the ith stock calculated using the data from day $t\text{-}D+1$ to day t, respectively.

2.2.2 Shapley Method

In game theory, Lloyd Shapley proposed the Shapley value in 1953, where he investigated and came up with a set of axioms that could uniquely determine the value of a coalition game (Shapley, 1953). The Shapley method calculates the marginal effect of the ith element within all the possible coalitions of the portfolio, and then determines the allocation of the risk capital to each subunit. For the Shapley methods with risk measure *VaR*, the risk capital allocation is calculated using the following equation below:

$$VaR_t(L_i|l_P) = \sum_{S\subseteq P, i\in S} \frac{(|S| - 1)! (n - |S|)!}{n!} (quantile_\alpha(L_t^S) - quantile_\alpha\left(L_t^{S\setminus i}\right))$$

where $t=T\text{-}D+1,\dots,T$, and $quantile_\alpha(L_t^S)$ represents the *VaR* of the coalition S at day t which is calculated using the loss of coalition S from day $t\text{-}D+1$ to day t. $|S|$ represents the number of stocks in the coalition S, and n represents the total number of stocks in the portfolio P. For the empirical study, total of 8 coalitions need to be considered for each of the stock i, and the value of $n = 4$.

For the Shapley method, the allocated risk capital is calculated as the following while using ES as the risk measure:

$$ES_t(L_i|L_P) = \sum_{S\subseteq N, i\in S} \frac{(|S| - 1)! (n - |S|)!}{n!} (\mathbb{E}[L_t^S|L_t^S \geq VaR_\alpha] - \mathbb{E}\left[L_t^{S\setminus i}\middle|L_t^{S\setminus i} \geq VaR_\alpha\left(L_t^{S\setminus i}\right)\right])$$

where $t = T\text{-}D + 1, \dots, T$, and $\mathbb{E}[L_t^S|L_t^S \geq VaR_\alpha]$ represents the ES of the coalition S at day t which is determined by the loss of S from day $t\text{-}D+1$ to day t. $|S|$ represents the number of stocks in the coalition S, and n represents the total number of stocks in the portfolio P.

2.2.3 Euler Principle

Noting that the Euler method has different versions in the literature. The paper focuses on the partial derivative definition of the Euler principle, which coincides with the Aumann- Shapley method in game theory. The Aumann-Shapley method was developed by Aumann and Shapley (1974), and it is an extension of the Shapley method as it allows one to deal with the non-atomic games / divisible portfolios. The Aumann-Shapley method reduces to the Euler principle when the risk measure is homogeneous of degree one and differentiable (e.g. *VaR* and *ES*) (Tasche, 2008; Li et al., 2016).

The following equation is used to calculated the *Euler-VaR-contribution* of the ith stock for the empirical study, where the derivative is computed manually:

$$VaR_t(L_i|L_P) = \frac{VaR_\alpha\left(L_t^P + hL_t^i\right) - VaR_\alpha(L_t^P)}{h}$$

the value of h is set to be 1 here, and $t=T\text{-}D+1,\dots,T$. $VaR_\alpha\left(L_t^P + hL_t^i\right)$ stands for the α-quantile of the loss of portfolio L_p plus h units of the ith stock over the period $t\text{-}D+1$ to t.

The Euler contributions while using the risk measure ES is quite straightforward compare to the *Euler-VaR contribution.* For the empirical analysis, the *Euler-ES-contribution* is calculated as the following according to Tasche (2008):

$$ES_t(L_i|L_P) = \mathbb{E}[L_t^i|L_t^P \geq VaR_\alpha(L_t^P)]$$

where $t=T\text{-}D+1,\dots,T$, and $\mathbb{E}[L_t^i|L_t^P \geq VaR_\alpha(L_t^P)]$ represents the *ES* of the overall portfolio at day t calculated by using the loss of the portfolio from day $t\text{-}D+1$ to day t.

2.2.4 Constrained Aumann-Shapley Allocation (CAS)

The Constrained Aumann-Shapley(CAS) allocation is a relatively new method developed by Li et al(Li et al, 2016). The paper *organising the allocation* pointed out that there exist counter intuitive results while applying the Shapley and Aumann-Shapley method to allocate capital for business units within banks in practice, and it is caused by the ignorance of the bank's organization constrains (Li et al., 2016). As a result, the CAS allocation is developed and it enables one to capture the organizational constraints of banks. The CAS allocation is the combination of the C-Shapley method and Aumann-Shapley method. Let S stands for all the possible sub-units of the portfolio proceeding stock index i. For each possible coalition S, the integration could be calculated with the value of q taking the value from 0.1 to 0.9, with the interval 0.1. Giving the coalition S, the conditional allocation of i using risk measure VaR is then calculated as the following:

$$VaR_t(l_i|l_S) = \sum_{q=0.1}^{0.9} \frac{\partial VaR_t(l_t^S + ql_t^i)}{\partial(ql_t^i)} \times 0.1$$

The unconditional allocation of index i at day t is then calculated by taking the arithmetic average of the conditional allocation of i at day t over all possible coalition S (Li et al., 2016):

$$u_t(l_i) = \mathbb{E}[VaR_t(l_i|l_S)]$$

For a given sub-unit S, the conditional allocation of i on day t with risk measure ES becomes:

$$ES_t(l_i|l_S) = \sum_{q=0.1}^{0.9} \frac{\partial ES_t(l_t^S + ql_t^i)}{\partial(ql_t^i)} \times 0.1$$

where q takes value from 0.1 to 0.9, and the interval is set to be 0.1.

The unconditional risk capital allocation of stock index i within the portfolio at day t is then calculated by taking the arithmetic average of the conditional allocation of i at day t over all possible coalition S:

$$u_t(l_i) = \mathbb{E}[ES_t(l_i|l_S)]$$

where $t = T\text{-}D + 1, \ldots, T$, P represents the constructed portfolio, and while calculating the allocation of the i^{th}index under all the possible permutations, S stands for the union of the indices within a specific coalition excluding the ith index.

3 Results

The risk capital of a portfolio that is determined by ES is always greater than the capital determined by VaR of the same portfolio($ES_\alpha \geq VaR_\alpha$). Due to the natural of the ES, which is effectively the average of VaR over all levels above the confidence level α (McNeil, Frey, and Embrechts, 2015). In order to study the daily allocation of the above methods with risk measure VaR and ES of the same scale, I choose to modify the allocation with risk measure ES in a way such that it becomes the same level as the VaR. And the following equation is used for rescaling:

$$ES_t(\widehat{L_t|L_P}) = \frac{VaR(L_t^P)}{ES(L_t^P)} \times ES_t(L_i|L_P)$$

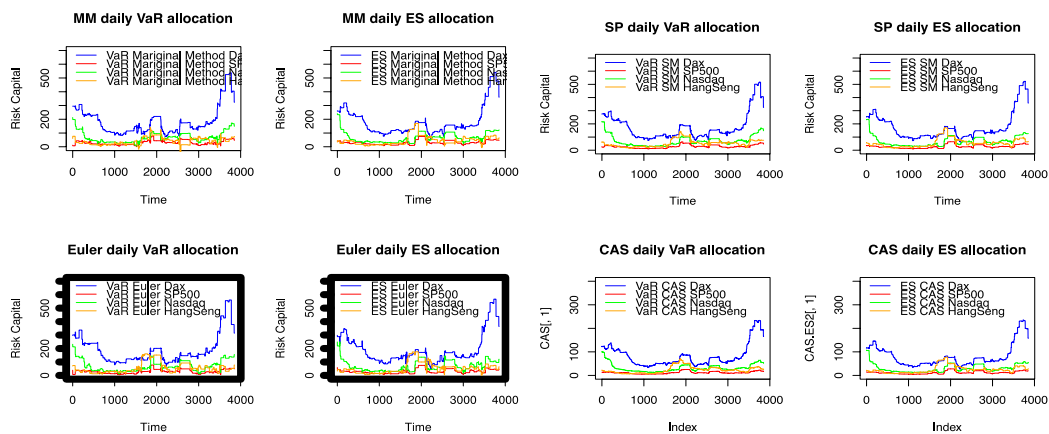
Applying the above equation to the allocations with risk measure ES would ensure the total amount of capital used for allocation on day t is the same no matter which risk measure is used.


Figure 1   Time Series Plots of Daily Allocated Risk Capital of the Four Stock Indices (With *VaR* and *ES*) fROM DECEMBER 2001 to December 2016, Using Marginal Method, Shapley Method, Euler Principle, CAS Allocation

It is obvious that the allocated capital of stock index DAX fluctuates more compared to the others; and as one would expect, the required risk capital increases during the 2008 financial crisis. Another interesting observation is that the allocated risk capital of stock index Hang Seng has negative value while using the marginal method. The interpretation of the phenomenon is that the Hang Seng index has negative correlation with the rest of the portfolio, which enables it to hedge against the other indices.

The plots of the daily risk capital allocation are non-stationary because the time series, especially the allocation of the DAX index, displays an upward trend, except it drops sharply at the end. Indeed, it would not be really meaningful to use the global tools, such as variance, to test whether the allocated capital with one risk measure is more stable than the other. Instead of using variance to access the stability, realized variance is used to evaluate the stability of the allocated risk capital over the chosen period. The realized variance is defined as the sum of the squared differences of the risk capitals on day t and on day t_1, which could be expressed using the following equation (Hansen and Lunde, 2004):

$$IV_i = \sum (\rho(l_t^i) - \rho(l_{t-1}^i))^2$$

where $\rho(l_t^i)$ and $\rho(l_{t-1}^i)$ stands for the allocated risk capital to the ith stock index on day t and on day t-1.

Table 1   Realized Variance

	DAX	SP500	Nasdaq	Hang Seng
Marginal VaR	87978	13572	28176	40857
Marginal ES	59090	5078	19326	28704
Shapley VaR	53277	2239	9913	9167
Shapley ES	45799	2048	11590	14137
Euler VaR	116549	12236	42259	33298
Euler ES	94135	8925	44232	47017
CAS VaR	6209	108	718	610
CAS ES	8015	407	2504	2923

Based on the integrated variance, while looking at the stability of allocation on individual indices, the allocation determined by the CAS allocation performs better than all the other allocation methods. And the CAS allocation with the risk measure *VaR* performs better than *ES* if accessing the stability based on the realized variance. In addition, it can be observed that the performance of the Shapley method and Euler method are not constant across all the divisions: the methods with risk measure *VaR* would result in more volatile capital than *ES* on subunits DAX and SP500, and less volatile capital on Nasdaq and Hang Seng. This phenomenon can be explained by the fact that the allocation process happens within the whole portfolio, the less stable allocation situation on the index Nasdaq and Hang Seng could be interpreted as a cost for a more stable allocation of a more volatile element (DAX and SP500) in the portfolio.

4 Conclusion

In this paper, a portfolio with four subunits is constructed in order to study the performance of allocation methods with the two different risk measures in practice. Understanding that the financial institutions would prefer allocation method with risk measure that provides less volatile risk capitals, the CAS allocation is suggested for application in the real world. Because the CAS allocation captures the organizational constraints of banks, and it outperformances all other allocation methods in allocating risk capitals since it results in the least volatile risk capital of all the elements in the constructed portfolio based on realized variance. It is observed that during the 2008 financial crisis, the allocated risk capitals would experience an obvious increase during the crisis and drop back to the normal level afterwards, regardless of the method used, this result is not surprising because the allocation is calculated according to the losses of the whole portfolio as well as the subunits, and the losses would definitely grow during the period of a crisis.

For future study, other assessments in additional to realized variance could be considered, which would make the comparison becomes more convincing. Furthermore, in this paper, there is no need to apply the Monte Carlo simulation while studying the Shapley method and the CAS allocation, as it is possible to calculate the allocation over all the possible coalitions because of the small portfolio size.

Therefore, for further study, the number of the portfolio and the divisions within the portfolio could be increased, so that the Monte Carlo simulation could be applied while studying the allocation methods.

Application of HSE Risk Management in Shipbuilding

Li Siqian, Yang Jiaqi
School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: siqian_lee@whut.edu.cn, styjq@whut.edu.cn)

Abstract: Shipbuilding projects are characterized by long time spans, various work types, long risk cycles, great difficulties in risk management, and social and ecological effects. This paper combines the application of HSE risk management in different industries, based on the research on mode of thinking, process and techniques of HSE risk management, applies HSE risk management in shipbuilding industry with a case study of jig frame fabrication activity. By identification, assessment and control of jig frame fabrication HSE risk, effectively improve abilities of risk management and reduce the likelihood of accidents in shipbuilding.

Key words: Shipbuilding; HSE risk management; Risk identification; Risk assessment; Risk control

1 Introduction

Shipbuilding industry is the epitome of modern big industry, it is not only providing equipment for water transportation, energy transportation and marine exploitation, but also offers naval vessels equipment, so it is one of the strategical industry for national economy and defense construction. However, as a labor-intensive, technology-intensive, capital-intensive industry of high risks, if accident occurred, it would cause enormous damage to people, assets and environment.So there are a lot of strict requirements of health, security and environment management in shipbuilding industry. Currently, HSE management system which is widely applied in oil and gas industry is a guideline for company's standardized management and sustainable development (Akalezi C.O., 2005). HSE risk management as the core element of the HSE management system is the basis to implement HSE management (Sun Xianchang, Wang Xiaomin, Xiao Zonglin, et al., 2010). When applying the HSE risk management model and techniques into shipbuilding, we can effectively control the occurrence of accident and guarantee the production objective of company or organizations.

HSE is a trinity system of Health, Safety, and Environment, which is an advanced internationally recognized management system. The International Maritime Report based on the Waltz liner oil spill and reef accident established the core position of risk assessment and accident prevention in HSE management system (Sun Weiqun, 1999). Five oil upstream companies including BP Amoco, Conoco Philips, Shell, Statoil ASA, Atlantic Richfield Company summarizes the better HSE risk management model and method through the comparison of HSE risk management performance (Gomm C., Brosnan C., Grundt H.J., et al., 2000). With the continuous development and improvement of safety sciences, environmental sciences, and systems theory, HSE risk management has been gradually applied to construction projects (Jafarnia E., Soltanzadeh A., Ghiyasi S., 2018), electric power industry (McLeanI., 1998; Bransby M.L., Jenkinson J., 1998), shipbuilding, as well as to medical industry (Li Hongbo, Zhong Liwei, Chang Jian, et al., 2017) and agrochemical industry (Fan Dongsheng, 2016). Shipbuilding industry as a high-risk industry is next only to the mining industry and construction industry, there already have been some HSE risk management researches on it, which include the establishment and implementation of the HSE management system in LNG shipbuilding projects (Li Yang, 2011), some extend to oceaneering projects about HSE risk management for JU200E jack-up drilling rig construction projects (Cao Yunfei, 2014).All these studies have proved the positive influence and role of HSE risk management in occupational health, safety, and environmental risk management of the industry or in related organization.

2 Framework of the HSE Risk Management

2.1 The mode of thinking of HSE risk management

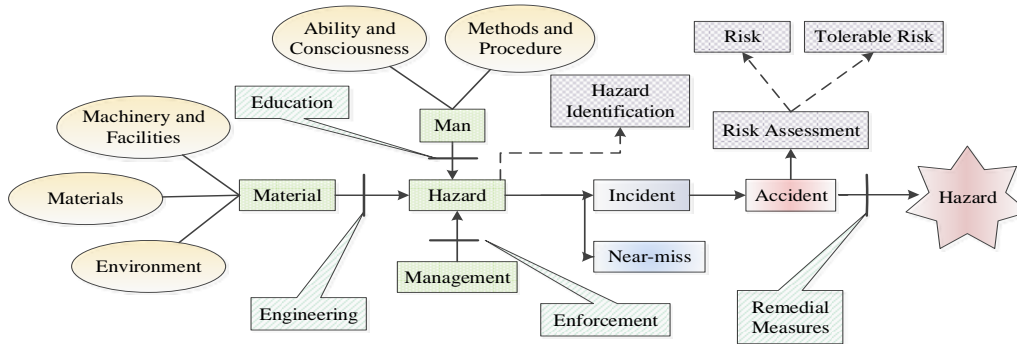
The core of HSE risk management is to eliminate hazards, by this way which the accidents can be prevented. Figure 1 (Zheng Shejiao, 2017) reveals the mode of thinking of HSE risk management, including the procedures of risk identification, risk assessment and risk control. And it also reflects the sources of systemic hazards (materials, machinery and facilities, working environment, ability and consciousness, methods and procedure) and main risk control measurement (engineering technology, education and training, enforcement management).


Figure 1   The Mode of Thinking of HSE Risk Management

2.2 The process of HSE risk management

In terms of the whole HSE management system, HSE risk management is a dynamic process of leaders' support and decision-making, total involvement and continual improvement. In order to point out the responsibility, objective and policy of risk management, the principle step for HSE risk management is to set up risk management group based on company's scale, nature and personnel quality. As the object of HSE risk management generally is complicated, complex system should be divided into unit or section, so the object of management is risk units or sections. On this basis, the early stage of risk management is to identify and analyze hazard factors, then assess the risk by the incidence probability and severity of consequences of each hazard factor according to the risk criterion. The later stage is to bring up measures to weaken, control hazard or meet emergencies based on the degree of hazard factors, ultimately form the plan and relative procedures for HSE risk management.

2.3 Techniques of HSE risk management

2.3.1 Risk identification techniques

The hazards in a complex system are multiple and difficult to recognize all-inclusively. Therefore, the method of risk identification should be scientific, systematic, comprehensive, targeted and operable. At present, combined with existing domestic and foreign research, common hazard identification methods include: information collection, inquiring survey, job hazard analysis (JHA), safety check list (SCL), event tree analysis (ETA), failure mode and effects analysis (FMEA), Hazard and Operability (HAZOP), etc. (Zheng Shejiao, 2017).

2.3.2 Risk assessment techniques

Risk assessment is based on the existing professional experience, statistical data, and evaluation criteria through a quantitative or qualitative means of scientific evaluation of the risk classification to determine the extent of its hazard and possible impact after the hazard factors are identified. Current risk assessment methods include: LEC (likelihood, exposure, and consequence), matrix method, pre-hazard analysis (PHA), failure mode and effects analysis (FMEA), brainstorming, etc.

2.3.3 Risk control techniques

Risk control is the fundamental purpose of risk management and the conduct of implementing risk management decisions. According to Heinrich's "3E countermeasures", risk control measures mainly include engineering, education and enforcement. By adopting appropriate measures, reduce and prevent the frequency of occurrence of accidents or damage caused by the accident. In the long-term safety management practice, seven types of more specific risk control measures are proposed. The effect of those measures from high to low are: elimination, substitution, reduction, isolation, procedures, reduction of employee contact time, and personal protective equipment.

3 Application of HSE Risk Management in Shipbuilding

Before the implementation of the shipbuilding project, the shipyard initiated HSE risk management with the goal of establishing and improving comprehensive risk management system and optimizing internal control. In response to the HSE risk of shipbuilding, the risk management team proceed from the project HSE goals, combine the actual conditions of shipbuilding, internal and external environments, and analyze various activities involving in HSE in the entire life cycle of shipbuilding from multiple dimensions by means of interviews, investigations, inspections, looking up the records. Ultimately shipbuilding system is divided into ten major production segments: preparatory technical work, lay off, blocks fabrication, slipway blocks assembly, outfitting, painting, ship launching, mooring

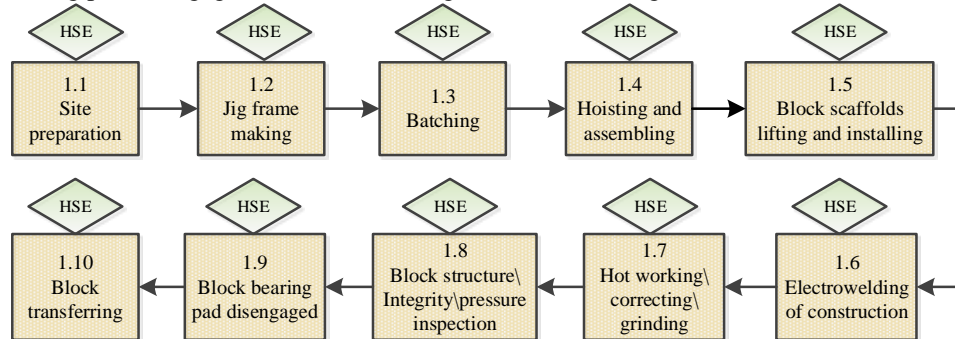
test, sea trail, and completion delivery. Further dividing production segments and taking blocks fabrication as an example, blocks fabrication can be divided into ten production units: site preparation, jig frame fabrication, batching, hoisting and assembling, block scaffolds lifting and installing, electro welding of construction, hot working\correcting\grinding, block structure\integrity\pressure inspection, block bearing pad disengaged, block transferring, as is shown in Figure 3.


Figure 3   Risk Units Analysis of Blocks Fabrication

Carry out risk identification of the jig frame fabrication unit in the blocks fabrication segment in shipbuilding adopting JHA method. Combining the basic operation activities, actual production status and past accident data of the jig frame production unit, obtain the main HSE hazards. Analyze the hazards identified, using incidence probability (L) and severity of consequences (S) to quantify magnitude of the risk, and formulate risk grading standards to determine the risk level: <20, class 1; 20-70, class II; 70-160, class III; 160-320, class IV; >320, class V. Propound targeted control recommendations with risk control techniques for management and control of the jig frame fabrication unit. The identified hazards, assessment results and control measures are shown in Table 1.

Table 1   HSE Risk Identification, Assessment, Control of Jig Frame Fabrication

No	Production Segment	Main Hazards	Main Results	L	E	C	D	Risk Level	Control Measures
1		Operators without security education, no certificates	Lifting injury	1	6	7	42	II	Certification and training
2		Overweight crane lifting capacity	Falling object hit	3	6	6	108	III	Strict accordance with the operating procedures
3	Jig materials lifting and moving	Slings lack of maintenance and rust damage	Lifting injury	6	3	3	54	II	Strengthen daily equipment maintenance
4		Inadequate binding of hanging loads	Lifting injury	3	6	6	108	III	Strengthen inspection prior to operation
5		Piles or people inside the lifting cordon	Casualties	1	6	6	36	II	Strengthen inspection prior to operation
6		Insufficient lighting	Lifting injury	3	6	3	54	II	Strengthen inspection of work environment
7	Jig installing	…	…	…	…	…	…	…	…
8		Welding staff without security education, no certificates	Fire, electric shock, hot burn, explosion	1	6	7	42	II	Certification and training
9	Jig electro welding	Without hot work permit	Fire, electric shock, hot burn, explosion	3	3	15	135	III	Strict enforcement of hot work permit
10		Improper or absent protective equipment	Electric shock, hot burn, industrial disease	3	6	3	54	II	Strict enforcement of dress code and protective equipment

Continual Table 1

No	Production Segment	Main Hazards	Main Results	L	E	C	D	Risk Level	Control Measures
11		Welder grounding failure	Electric shock	3	6	7	126	III	Strengthen inspection prior to operation
12	Jig electro welding	Combustibles in affect region	Fire, explosion	1	6	7	42	II	Strengthen inspection prior to operation
13		Poor ventilation	Fire, explosion	3	6	3	54	II	Strengthen inspection of work environment

4 Conclusion

This paper focuses on the practical application of HSE risk management in shipbuilding. Based on the actual status of shipbuilding, identify, assess and control the risk of jig frame fabrication unit in shipbuilding, and put forward proposals and research outlook as follows:

The great investment and high risk of shipbuilding determines the necessity of HSE risk management. HSE risk management group should set reasonable HSE risk management objectives, select appropriate risk identification methods for risks at different stages and with different operational characteristics, encourage full participation in the confirm of hazard and degree of impact, and balance the relationship between risk control cost and risk levels.

The implementation of the HSE risk management process should be accompanied by strict documentation procedures, supervision and auditing, follow-up and training, follow-up study will be about the implementation and operation of these elements.

Abstract: Whether the relationship between the government and listed companies is clearly regulated has a great impact on the efficiency and quality of financial information disclosure management. This paper, therefore, conducts an in-depth analysis of the interests of the government and listed companies in the financial information disclosure management. It analyzes the actions and motivations of governments at all levels and listed companies through constructing the static and dynamic game models of governments at all levels and listed companies in financial information disclosure management, and puts forward corresponding suggestions in a targeted manner based on the analyses.
Key words: Finance; Information management; Government; Listed companies; Game analysis

1 Introduction

Nowadays, with the continuous improvement of China's government supervision system, the disclosure system of corporate related financial information has basically taken shape. The disclosure of related financial information, however, is still far from perfect. Financial irregularities such as incompleteness and delay in disclosure, non-disclosure is not uncommon. Therefore, there is an urgent need to strengthen the supervision of corporate financial information disclosure. This paper employs the game model to conduct an in-depth analysis of the interests of the government and listed companies in the financial information disclosure management, and strives to build a benign interactive relationship between the two sides, and thus promoting the efficient management of financial information disclosure.

2 Research Review

For a long time, it is natural for academia, industry, or government management agencies to assume that government is completely independent, has a fair and unselfish attitude, rich governance experience, moreover, it is able to make scientific decision and harbors good wishes. Therefore, since the information disclosure system is established to protect the interests of the investing public, it will be able to achieve its intended goal (Reesse, 2002). However, American economist Geogre.JitSgler first proposed different opinions as early as 1964, supporting "the uselessness of regulation.Professor (Shen Yifeng, 1998) used Stigler's empirical test method to compare the purpose and actual effect of the "Provisional Regulations on the Administration of Stock Issuance and Transaction" promulgated by the CSRC, and concluded that the efficiency of government supervision is limited and conditional. (Cui Xuegang, 2004) analyzed information disclosure problems in listed companies to explore government's role and function in the process of financial information disclosure of listed companies. (Wu Weirong, 2018), taking the A-share listed companies in Shenzhen and Shanghai from 2003 to 2015 as a sample, focusing on the issue of voluntary rotation, investigated the problems of auditing quality affected by CPA and term transitional CPA under tenure management and explored the regulatory role of government regulation in these two effects.

3 Game Model Construction

The process of financial information disclosure management is actually a gaming process between governments at all levels and listed companies. On the one hand, on the government side, they hope to conduct financial information disclosure management rapidly with minimal social costs (including economic costs) to maximize social stability and development. On the other hand, listed companies, based on the role of rational economic agents, make great effort to maximize their own interests, including both economic interests and social interests, and adopt information dissemination and other means to obtain more benefits. Disclosure of a listed company's own financial information allows its potential investors to fully understand its business situation, and encourages them to invest in the company. Investors will consider the cost of investing and endeavor to gain greater benefits (including both economic and social benefits) from it.

Based on the above analysis, the article puts forward the following assumptions for the construction of the two-side game model.

Hypothesis 1: The main body of financial information disclosure management is governments at all levels and listed companies, both of which are rational economic actors. That is to say, the pursuit of maximizing their own interests is their respective goal, so that conflicts of interest between them in their respective actions are inevitable.

Hypothesis 2: Listed enterprises faced by governments at all levels are collectives with consistent actions and objectives. In the actual process, however, these collectives often break apart under the influence of government while pursuing their own interests.

Hypothesis 3: Information is asymmetric. Governments at all levels have absolute advantages in management of financial information disclosure, whereas resistance actions and targets of listed companies put them at an information disadvantage.

Hypothesis 4: Once a listed company succeeds in a corporate resistance, the government and officials at the same level will face penalty imposed by the higher level government.

4 Analysis of Static Game Models of Governments at Different Levels and Listed Companies

Based on the above assumptions, in the process of financial information disclosure management, governments at all levels take legal or irregular action strategies to obtain their own social interests. The strategy of listed enterprises is to resist or cooperate with government. Therefore, the static game model for building government and listed companies is shown in Table 1.

Table 1　Static Game Models of Government and Listed Companies

		Listed Companies	
		Cooperation	Resistance
Government	Legal Means	A，B	A-C，$B+b_1$-C
	Irregular Means	A+b，$B-b_2$	A+b-F，$B+b_1$-F

In the static game model of the two sides, "A" represents the profits government gain in financial information disclosure management in a legal manner. "B" is the legitimate profits obtained by listed companies in their financial information disclosure activities (including economic benefits and social benefits). "C" stands for the economic and social costs required for the government to conduct financial information disclosure management in a legal manner and the listed companies to execute it. "F" represents the conflicting costs borne by government due to its irregular disclosure management of financial information and the resistance of listed enterprises. At the same time, it is assumed that the conflicting cost is zero if government conduct financial information disclosure management in a legal manner and listed companies conduct financial information disclosure in a cooperative manner (including execution costs and conflict costs). "b" represents the expected additional benefits government gain in the irregular management of financial information disclosure. "b_1" stands for the expected additional benefit gained by a listed enterprise taking the strategy of resistance. "b_2" is the expected revenue loss borne by listed companies due to the government's irregular management of financial information disclosure. It is obvious that F is greater than C (F>C).

The relationship between governments at all levels and listed companies is a single-stage static game. Based on this, this article draws some conclusions after analyzing the choices made by governments at all levels and listed companies.

(1) In the case of $A+b-F>A$, where the profits obtained by governments at all levels in the irregular management of financial information disclosure is greater than that gained in legal management of financial information disclosure, governments at all levels will prioritize irregular means.

At the same time, what the listed companies need to consider in strategy choice is the value size of "$B-b_2$" and "$B-b_1-F$". If "$B-b_2$" is smaller than "$B+b_1-F$" ($B-b_2 < B+b_1-F$), listed companies adopt resistance strategy. Listed companies believe that the resistance strategy will increase government's management cost of financial information disclosure, and may trigger higher-level government to impose penalties on the government at this level, which will urge the government at this level to make concessions; thereby they can obtain more benefits from it. If "B-b_2" is greater than

" $B + b_1 - F$ " ($B - b_2 < B + b_1 - F$), listed companies will adopt a cooperation strategy.

(2) In the case of $A > A - C > A + b - F$, government's strategy choice depends on the listed companies'. When listed companies choose resistance, governments at all levels will conduct financial information disclosure management in a legal manner. If listed companies adopt a cooperation strategy, the best strategy for local government is to conduct irregular management of financial information disclosure.

(3) In the case of $B + b_1 - F > B$, resistance strategy is preferable to listed companies. Whether government conduct financial information disclosure management in an irregular manner is determined by the value size of $A - C$ and $A + b - F$.

(4) In the case of $B - b_2 < B + b_1 - F < B$, listed companies' behavior choice relies on that of government. If government conduct financial information disclosure management in an irregular way, the best strategy for listed companies is to take resistance actions, then Nash equilibrium is " $A + b - F , B + b_1 - F$ ". If government conduct financial information disclosure management in a legal manner, the best strategy for listed companies is to cooperate with government, then Nash equilibrium is "A, B".

(5) In the case of $B + b_1 - F < B - b_2$, cooperation strategy is preferable to listed companies. Government conduct financial information disclosure management in an irregular way, and Nash equilibrium is " $A + b, B - b$ ".

5 Analysis of Dynamic Game Models of Governments at Different Levels and Listed Enterprises

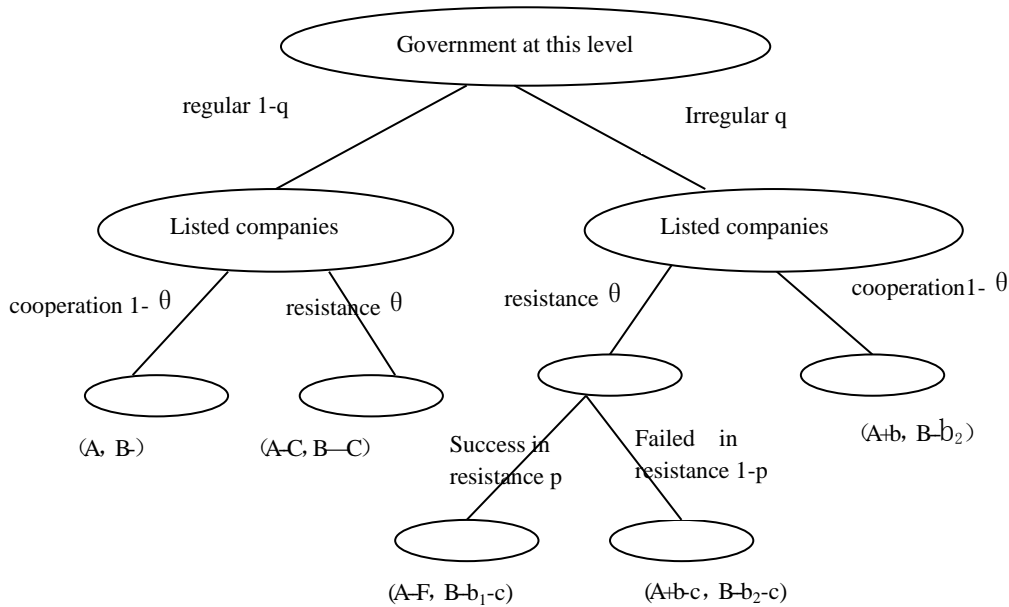
In actual work, the gaming ability of governments at all levels and listed companies is asymmetric in the process of financial information disclosure management. As listed companies are in a passive state, government at all levels take absolute advantage in information management. However, actions taken by government at this level are subject to supervision by higher levels of government. If a listed company succeeds in resisting the government's irregular management of financial information disclosure, local government may face penalty imposed by the higher level government. In view of the above analysis, the focus of government and listed companies when they decide what strategy should be adopted is listed companies' willingness to take resistance actions，the probability of successful resistance (p), and the cost (F) listed companies have to bear if government conduct financial information disclosure management in an irregular way. The cost (F) here includes not only the increased comprehensive cost (F_1) due to the resistance of listed companies, but also the penalty imposed by the higher level government (F_2). It is assumed that if government and officials at this level found to be conducting financial information disclosure management in an irregular way would incur severe penalty, the government would take the risks and costs into account while conducting irregular management. Therefore, the gaming playing between the two sides is a mixed strategy game behavior. The game model is as follows:


Figure 1   Dynamic Game Model of Government and News Media

Taking risks and costs into account, governments at all levels will decide whether to conduct financial information disclosure management in an irregular way. In figure 1, "q" represents the probability of government taking irregular measure. The pursuit of an optimal strategic combination for the two sides is a process of seeking a mixed strategy Nash equilibrium.

Assume that the government's hybrid strategy is $h_1 = (q, 1-q)$. The probability of government conducting financial information disclosure management in an irregular manner is "q", and the probability of government conducting financial information disclosure management in a legal manner is "$1-q$". Assume that the mixed strategy of a listed company is $h_2 = (\theta, 1-\theta)$. The probability of the listed company taking resistance action is "θ", and the probability of the company adopting cooperation means is "$1-\theta$". "p" represents the probability of the company's successful resistance when government conduct irregular management, and "$1-p$" stands for the probability of the company' failure in these actions. One more assumption is made that the probability of the company's successful resistance under the government's legal management is zero. Then the expectation function of governments at all can be shown in Figure 1.

According to the above analysis, the game model has no Nash equilibrium. This paper can deeply analyze the optimal behavior choices made by two sides, and choose the optimal one from the hybrid strategy through comparing two parties' expectations.

(1) Optimal behavior choices made by governments at all levels.

The expectation of government at all levels conducting financial information disclosure management in an irregular way is:

$$U_1 = \theta P(A - F) + \theta(1 - P)(A + b - C) + (1 - \theta)(A + b)$$

The expectation of government at all levels conducting financial information disclosure management in a legal way is:

$$U_2 = (1 - \theta)A + \theta(A - C)$$

Whether the government chooses to conduct financial information disclosure management in an irregular manner depends on the value size of U_1 and U_2. The greater the value size of $\Delta V = V_1 - V_2$ is, the greater driving force and motivation the governments at all levels own while conducting financial information disclosure management in an irregular way.

$$\Delta U = U_1 - U_2 = b(1 - \theta P) - \theta P(F - C)$$

As can be seen from the above formula, whether governments at all levels choose to conduct financial information disclosure management in an irregular way is mainly determined by the specific

situation when listed companies take resistance actions, as well as the profits governments at this level have gained through irregular management and the penalties for their violation of regulations. Smaller probability (θ) of a listed company choosing resistance action would lead to smaller probability (P) of its success in resistance. More benefits (b) obtained through financial information disclosure management in an irregular way would lead to greater probability of governments at all levels conducting management in this way. In addition, governments at all levels are more inclined to conduct financial information disclosure management in irregular ways, when the penalties (F) for irregular management of financial information disclosure and the costs of conflict (C) are closer. Therefore, if the higher-level governments intensify the investigation and punishment of irregular management of financial information disclosure, even if the value size of θ, P, and F increases, irregular behaviors of government at the same level will decrease in the process of financial information disclosure management.

(2)Optimal behavior choices made by listed companies.

The expectation of a listed company taking resistance action is:

$$V_1 = (1-q)(B-C) + qp(B + b_1 - C) + q(1-p)(B - b_1 - C)$$

The expectation of a listed company adopting cooperation strategy is:

$$V_2 = (1-q)B + q(B - b_2)$$

The expected difference   ($\Delta V = V_1 - V_2$)   of the above two expectations.

$$\Delta V = V_1 - V_2 = qp(b_1 + b_2) - C$$

The above formula reveals that whether a listed company adopts resistance strategy or not depends on the probability （ q ） of government conducting irregular management of financial information disclosure, the probability (p) of the company's successful resistance, the comparison of the benefits gained from successful resistance（ b_1 、 b_2 ）, and the costs of resistance. In the process of financial information disclosure management, as listed companies are at a disadvantageous position, the chance of successful resistance is slim.

According to the analysis (1) and (2), it is obvious that due to their unbalanced status, the government being in a advantageous position and listed companies being in a disadvantageous position, what concerns governments at all levels is not listed companies' resistance action, but the penalties imposed by higher level government due to their violation of regulations. Therefore, in the process of financial information disclosure management, governments at all levels usually focus on dealing with various adverse problems caused by irregular management, such as preventing listed companies from publishing real financial information, deceiving or bribing superior supervisory authorities, rather than aiding increasing interests of listed companies. What's more, in practice, the ability of government bearing the risks and costs is far greater than that of listed companies at the same level. However, if higher-level government clarify individual responsibilities and conduct tougher punishment for the officials violating regulations in the process of management, it will form a powerful deterrent to governments at all levels and officials, which is helpful in reducing violations of regulations. The main driving force for local government to violate regulations and listed companies to take resistance actions is to obtain more benefits from financial information disclosure management. Therefore, clear and reasonable distribution of the benefits from it will help to prevent government and listed companies from falling into a game dilemma (violation & resistance).

6 Suggestions on Game Analysis
6.1 Making strict regulations on government's powers and obligations in listed companies' financial information disclosure management

Nowadays, under the guidance of the ideological concept of guaranteeing market economy stability, governments at all levels are given great power to manage financial information disclosure of listed companies, so that powers and obligations are not equal. The great discretion of government enables them and their officials to gain more benefits in the process of management. Therefore, great efforts must be made in the following aspects: improving relevant laws and policies, making strict regulations on the powers and obligations of governments at all levels in the process of listed companies' financial information disclosure management, ensuring equality in powers and obligations, establishing scientific, standardized and transparent management system, effectively protecting the vital interests and social

interests of listed companies and investors. All of these will increase the costs of violating regulations, thus reducing the chance of government gaining illegal benefits from it.

6.2 Creating a loose business environment, so that listed companies are more autonomous in crises

It is necessary to improve the laws and regulations on listed companies' financial information disclosure management, clarify the financial information disclosed by listed companies, disseminate the rights and responsibilities of financial information, give listed companies maximum right of freedom to disclose information, regulate both the content and the form of the financial information disclosed by listed companies in terms of social needs and public demand. Furthermore, it is desirable to establish and improve the supervision mechanism and correction mechanism of financial information disclosure, and create a loose business environment, so that listed companies are more autonomous and free in the crises.

6.3 Strengthening the supervision and management of financial information disclosure to protect the vital interests of government and listed enterprises

There are two main reasons accounting for why governments at all levels conduct financial information disclosure management in irregular ways. First, the benefits from irregularities are greater than those from compliance with regulations. Second, the penalty for irregularities is less than the opportunity cost of irregularities. Therefore, it is needed to strengthen the supervision and management of financial information disclosure, take effective measures to reduce the profits from irregularities and increase the penalty once irregularities found. Specific measures can be as follows. Firstly, information technology can be used to conduct dynamic supervision. A dynamic monitoring system for financial information disclosure management can be established to improve the probability of government conducting financial information disclosure management in irregular ways. Secondly, a smooth external supervision channel can be established to give full play to the supervision role of social groups, network forces and public forces, and make sure that listed companies learn the truth, participate in and supervise the management of financial information disclosure.

6.4 Intensifying the enforcement of financial information disclosure management for listed companies

It is necessary to give full play to the strength of the social and legal community to support listed companies conducting financial information disclosure. Social legal communities should provide listed companies with legal advice on issues related to financial information disclosure management. When government violates laws on financial information disclosure management, listed companies can make legal appeals. Relevant law enforcement agencies should intensify the management of financial information disclosure. When governments at all levels violate these regulations, it is necessary to strengthen investigation and punishment, clarify leadership responsibilities and severely punish officials who violate regularities.

7 Conclusion

The relationship between government and listed companies in accounting information disclosure is complicated. It is not only a static game between listed companies and regulatory agencies, but also a multi-party dynamic game. It involves other participants including outsiders who are trying to know internal information, such as other listed companies, creditors of listed companies, accounting firms and so on. In reality, the violation of listed companies is often conducted by supervisors who instruct or force accountants to do so, which will have a major impact on the game process. Due to the complexity of model representation and the inconvenience of data acquisition, the model used in this paper cannot test the reality very well. Therefore, further research and analysis will be carried out in the future.

Abstract: With the increase of research funds in colleges and universities, more and more attention has been paid to improve the proper usage and efficiency of research funds. The paper introduces the immune system into the internal audit and studies the specific immune functions, such as defense function, recognition function, reveal function and repair function. This paper puts forward the basic idea of the internal audit procedure of research funds based on immune functions, and concludes that the immune-based internal audit can identify, reveal, repair and prevent the problems existing in the whole process of the research activities, so as to improve the efficiency of research funds.
Key words: Immune system; Immune functions; Internal auditing; Efficiency of research funds

1 Introduction

With the rapid development of China's economy, the intensity and scale of investment in scientific research have increased rapidly. According to the science and technology funds statistics of Ministry of Finance, the research and develop investment intensity of GDP accounted for more than 2.05%, which outnumbered the average 1.94% investment intensity of EU 28 countries. However, with the increasing of research funds, there is more and more misusage of research funds. According to the survey report of 2014 the Audit Commission: only 40% of research funds were used for research projects. One key reason for the improper usage of research funds lies in the leader-in-charge system. The research project leader has the entire right to control the whole expenditure of the fund, which is prone to misusage and waste.

An effective supervision system should be established to prevent and reduce such problems, without which the usage efficiency of research funds will be affected and the stability of research team will be endangered [1-2]. The current supervision situation of research funds in our country can be seen as "zero prior-management, ambiguous process management, rough post-management", which is difficult to be changed by the post-supervision based external audit.

Internal audit as an important means of supervision of research activities is different from external audit. It has the immune function with the main goal of prevention and process control [3-5]. In the internal audit, the audit department can supervise the audit object at any time, and play the role of warning and preventing in time. A good internal audit operation mechanism can regulate the use of research funds, improve the efficiency of research funds use, and help to promote the achievement of input performance objectives in science and technology research work.

There are lots of achievements on the research of the immune function in internal audit in the management of research funds. (Meng & Zhang, 2010) introduced the research of immune function into the field of internal audit, and highlighted the preventive effect of internal audit. (Xiong et al. 2017) analyzed that the internal audit had the immune effects of defense, surveillance and repair, which formed the immune system composed of "early risk warning, internal control mechanism, continuous supervision".

2 Analysis on the Immune Function of Internal Audit of Research Funds in Colleges and Universities

In order to change the situation of "zero prior-management, ambiguous process management, and rough post-management", it is necessary to carry out the four kinds of immune function "defense, recognition, reveal and repair" in internal audit [3-5], that will be beneficial to find the potential risk early, and avoid more serious problems.

2.1 Immune function

The immune function of organism is mainly manifested in three aspects: immune defense, immune stability and immune surveillance. (1) Immune defense refers to the function of the body to remove

pathogenic micro-organisms or other foreign matter, (2) Immune stability refers to the function of the body to remove damaged or senescent cells and maintain its physiological balance, (3) Immune surveillance means that the body recognizes and clears the mutant cells in the body to prevent the occurrence of tumors.

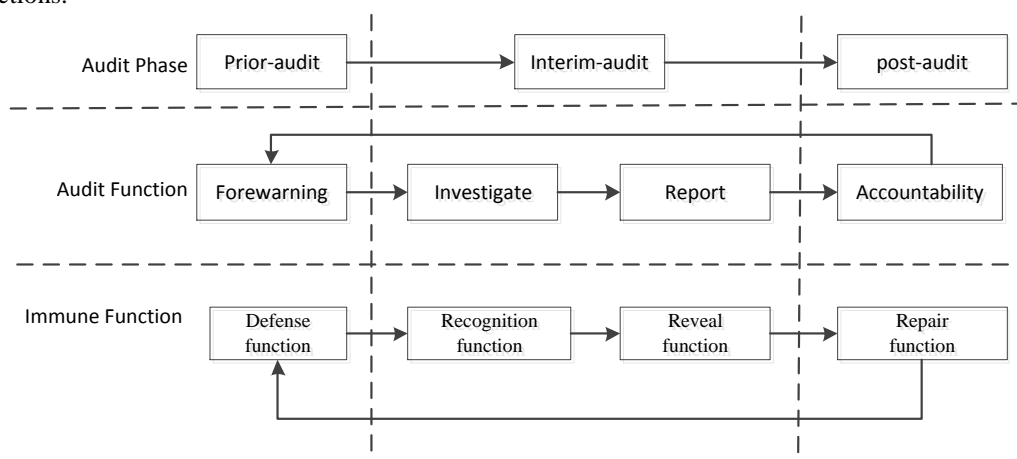
Similar to the immune function of organism, there are independent immune functions in the internal audit, which cooperate with each other and play the role of "immune system". The functions of the immune system in the audit process are recognition function, reveal function, repair function and defense function. Figure 1 illustrates the relationship of internal audit process and four immune functions.


Figure 1　Immune-Based Internal Audit Process and Functions

(1) **Recognition function**: Internal audits with immune function can identify potential damages and risks. If there is abnormal information or risks, the immune system will automatically warn early, and provide sufficient information for the system to develop preventive measures and to avoid loss, using various funds safely and effectively.

(2) **Reveal function**: When the immune system is unable to resist the risk, the system will automatically open the reveal function, and warn the improper behavior, indicating the existence of risk. At the same time, the immune system can quickly and effectively deal with the found risk, and produce a considerable deterrent to potential risks to reduce losses, ensuring the safety and integrity of funds.

(3) **Repair function**:　Immune system can adopt the constructive views of all sides, sort out and summarize the collected information. Besides, it can analyze and dispose the feedback of all sides, rectify the problems revealed by the internal audit immune system, to repair the system and finally to promote the internal audit department to clarify their responsibilities. At last, it can strengthen the management of the audited project, and improve efficiency.

(4) **Defense function**: After the repair of the internal immune system, the system can identify the unfavorable factors or risks, and exclude identifiable risk from the system, to curb the risk in the budding stage, thus to strengthen the whole immune system's defense, reducing the loss of project funds as far as possible.

2.2 Recognition function of internal audit --- identify problems

Considering the internal audit information system in colleges and universities, we need to find out the weaknesses of the system, and to equip the "automatic monitoring device" with the establishment of the real-time audit monitoring if we want to identify the problems and risks in the system [5]. The main problems and risks in the use of university research funds are: expenditure on outsourcing, lack of coordination and supervision of research equipment purchase, no list of office supplies, optional and casual travel reimbursement and so on. Therefore, in the process of research project, we need to introduce immune-based internal audit, which can identify the high risk issues timely and put the audit checkpoint ahead.

2.2.1 Expenditure on outsourcing

With the development of society, "professional people to do professional things" has become the general trend in research work. So the professional works, such as testing, commissioned processing, are generally entrusted to the specialized agencies. Research work outsourcing has become an important part of research. From the practice of internal audit, there are complex types of outsourcing. But the

focus of outsourcing contracts and the expenditure audit includes: Is the expenditure budget of the project reasonable? Is the use of expenditure standardized? Is the expenditure real? Is there related party extracted for the project funds? Etc.

2.2.2 Lack of coordination and supervision of equipment purchase

The equipment spending of research funds is one of the main concerns of the internal audit. Because the devices are managed as fixed assets, which should be purchased by procedures of public bidding of school or government procurement, and the related materials should be confirmed by the school and then to handle the receiving note of fixed assets. Fixed assets accounting can only be done after the equipment invoice. Purchase contracts and receiving notes should be audited by the school financial department. And the management of the process and the reimbursement procedures should be standardized. At the same time, whether the equipment purchase in the research funds is reasonable, whether the school can adjust or share in order to avoid the waste of research funds cannot be determined.

Due to the lack of coordination and supervision, the phenomenon of using the research funds to take the repeated purchase of equipment occurs frequently, which seriously affects the usage efficiency in the research funds. In addition, it is possible to use personal equipment (computers, air conditioning) as the research funds, resulting in the vain cost of research. Therefore, the internal audit department should be involved in the budget of research projects in advance, to reasonably estimate the correlation and necessity of research equipment and projects.

2.2.3 No detailed list of office supplies

From the audit practice, there are large amounts of expenditure reimbursed as "office supplies" in the research project funds, without specific name, number and price on the invoice. Seen only from the invoice, it's difficult to determine whether the items are reimbursed for research office supplies. Besides, the invoice management is not standardized. No matter what the customers buy, maybe personal consumption necessities, businesses will generally meet the customer's demand as long as the customer demand for "office supplies" invoices. Frequently personal costs are included in the research cost, which virtually increases the cost of research. So it's hard to make the accurate accounting of the actual benefit by research funds.

2.2.4 Casualness of travel expense

Due to the need of field research activities, or participation in seminars, etc., the cost of research funds includes a large number of travel expenses. Internal auditors can see numbers of the people, time, place, and the costs of travel from the reimbursed transport costs and accommodation bills, but it's difficult to determine whether the travel expenses are associated with research projects, and whether it is reasonable. Financial data may include travel expenses that should be assumed by an individual or other travel expenses in the cost of research, so the internal audit department should remove the inflated travel expenses from the cost of research, to ensure the reasonable and real expenditure of research project funds.

2.3 Reveal function of internal audit --- revealing problems

How to effectively solve the problems after identifying, that is the second important responsibility of immune audit. After identifying a series of problems through the management of research funds, we need to expose the problems, to deter potential risks and establish the authority of audit [3].

2.3.1 Disclosing the found problems and potential risks

All the problems are reflected and identified from the procedures, and these problems bring great obstacles to the future audit. Therefore, we should put the immune-based audit into management practice in research funds, using the information system to collect expenditure information of research funds, then establishing the dynamic monitoring and auditing system to prevent possible risks, and timely disclosing the found problems and potential risks, so as to avoid the waste of research funds. At the same time, the internal audit department should assess the risks and define the degree of risks, to warn in the process of revealing problems timely. Also, it is necessary to standardize the consequent use of research funds, to avoid serious problems in the research team and improve the use efficiency of the research funds.

2.3.2 Publicizing the project audit results

Publicizing the audit results of university research funds timely and periodically by the audit department is conducive to the real objective evaluation of research projects from the perspective of the third party. This is also an important way to use the audit results, with the power of the publicity to promote non-standard use of funds to be rectified which can also play a warning role for other research projects funds.

2.4 Repair function of internal audit - repairing problems

Repairing problem is the main procedure in immune-based audit, which will effectively integrate the audit resources, clean the reveled problems outside the system, and effectively repair the immune system audit [8].

2.4.1 Establishing accountability system

The accountability system of research activities is an important part of the immune system audit. Therefore, we should strengthen the construction of accountability system and the supervision of research funds as soon as possible and to improve the immune audit. Accountability system is essential in the management of research funds in colleges and universities. Colleges and universities should formulate relevant regulations timely, and take the strict accountability of the violation of discipline. Only by the clear authority of the internal audit department can we deter potential risks, and better fulfill the internal audit supervisory functions.

2.4.2 Improve financial processes and standards

At present, many of the provisions on the use of research funds are still in the general restrictions, without specific implementation of standards. Besides, some standards have not been modified for so long time, which falling behind the current situation. At the same time, all kinds of information system in colleges and universities are also in the process of construction. When there are new problems in immune function, the relevant standards and procedures should be improved timely according to current situation and the existing kinds of information.

2.5 Defense function of internal audit -- preventing problems

It is the defense process of immune system to effectively discover the "old problem" and produce effective "immune" function of the audit. Through the immune audit, the system can effectively identify and reveal problems, control risks, and solve problems through the establishment of a series of measures, such as perfect the management system of research funds in colleges and universities, establish appropriate accountability mechanisms, formulate specific rules for using research funds, regulate the use of university research funds, and strengthen "immunity" of internal audit gradually.

In the audit process, as long as the audit staff carries out the audit theory of "immune system", it will be able to reveal new problems timely and accurately, solve the problems, and ultimately prevent new problems. Therefore, it will prove that the introduction of the "immune system" theory in the audit of research funds is an important way to strengthen the immune system and improve the efficiency of the use of research funds.

3 Immune-Based Internal Audit Process of University Research Funds

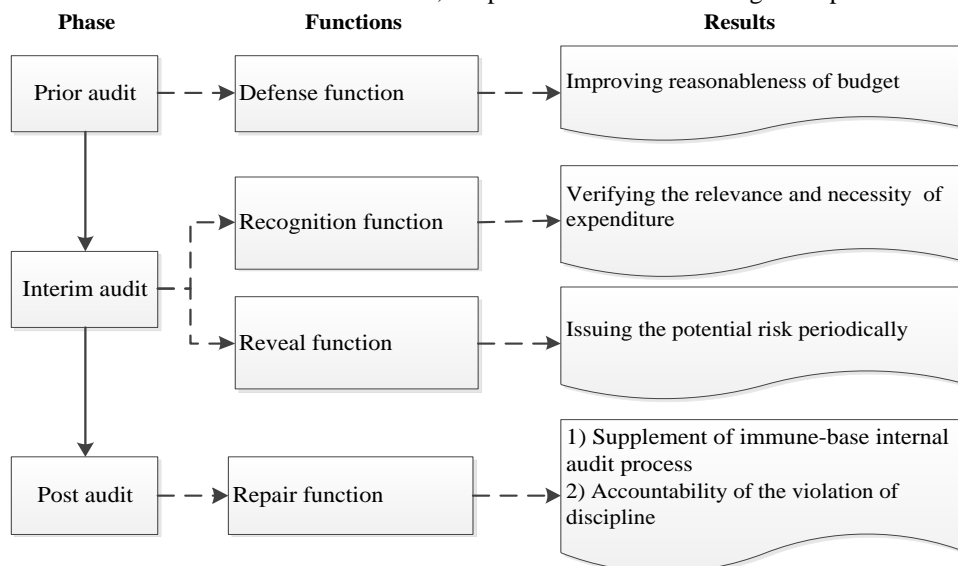
Most of the internal audit process of research funds in colleges and universities has the closing audit only after the accomplishment of the project, lacking in the prior audit and interim audit. In order to achieve the immune function of internal audit, we put forward the following audit process:


Figure 2   Process of Internal Audit Based on Immune System

In prior audit phase, by using defense function, internal immune audit check the budget of contract to find the unreasonable budget, such as repetitive purchase of equipment. It is helpful to improve the efficiency of research funds, avoid misusage of research at the beginning of project.

In interim phase, using recognition and reveal function, internal immune audit expenditure of project on authenticity, relevance and standardization periodically, to find the misuse of the research fund, such as outsourcing fee, equipment fee, labor service and travel expense, and so on. That will identify, reveal early risk warning and supervise the use of project funds continuously.

In post audit phase, internal audit should sum up the experience, supplement and improve the immune-based internal audit process, start the accountability mechanism if there is illegal use of the research fund.

The introductions of audit immune system in the audit of research funds in universities not only explore the immune function of internal audit, but also effectively promote the internal audit level of research funds to advance to prior audit and interim audit and run through the entire process of funds audit. At the same time, it strengthens the supervision of research funds, reduces the audit risks, and forms a cycling "firewall", which can detect, prevent, eliminate "disease" and repair the immune system timely, to ensure the safe operation of the system and to achieve an effective monitoring of research funds, and finally improve the efficiency of research funds.

4 Case Study

Take project numbered No.61178093 of W university funded by the National Natural Science Foundation of China as an example. The project funding is 580, 000 RMB. Immune-based internal audit supervise research activities in the whole process. By defense, recognition, reveal and repair functions, the immune-based internal audit identify some potential risks, reduce some improper use of research funds, and propose some rectify measurement. Table 1 illustrates the results of immune-based audit on this project in whole process.

Table 1　Case study for Immune-Based Internal Audit of a Research Project of Wuniversity

Phase	Functions	Efforts	Results
Prior audit	Defense function	Budget compliance securing	repetitive equipment fee 82,300 RMB reduced labor service fee 20,000 RMB increased
Interim audit	Recognition function	unnecessary expense identifying	unnecessary travel expense 24,560 RMB identified unreasonable equipment fee by 28,650 RMB identified unrelated part outsource fee 40,000 RMB identified unrelated office supplies fee 16,786 RMB identified
	Reveal function	Common misusage summarizing and reporting	Issue semi-annual report 8 times
Post audit	Repair function	Rectifying suggestions	Propose rectification measures Sum up experience, supplement internal audit process, strengthen immune function.

In this case study, the 102,300 RMB in contract budget was adjusted for use, 10,996 RMB improper use of research fund was rectified by immune-based internal audit.

After analyzing the use of the case project funds, the comparative results of each part effectiveness of the research funds before and after the immune audit are showed in Figure 3.

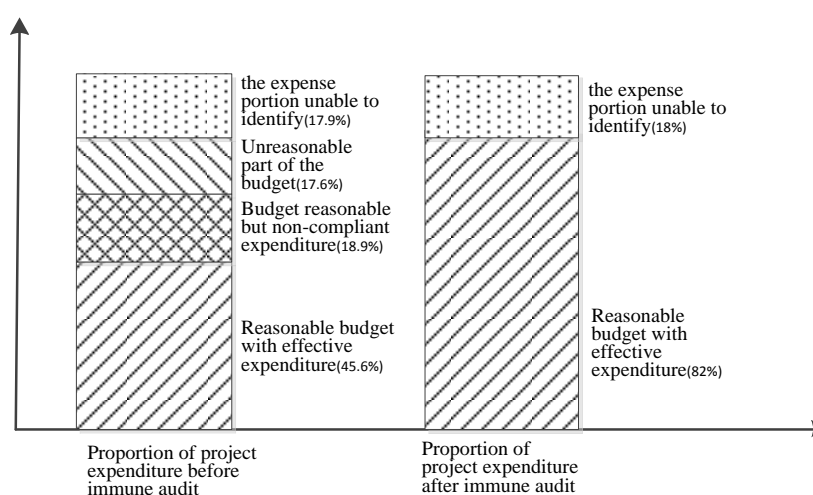
As can be seen from the above figure, the effective research expenditure before the immune audit is only 45.6%, and about 40% of the budget is unreasonable or non-compliant. By immune-audit methods, the use of unreasonable budgets and non-compliant funds has been effectively reduced, and the effective use rate of funds has been raised to about 80%. The effect is remarkable.


Figure 3　Effects of Rational Use of Research Funds on Immune Audit

5 Conclusion

From the current situation of the internal audit of colleges and universities, the realization of its functions is more passive defense, less active surveillance, and far from elastic stability. As the supervisor of the use of research funds in colleges and universities, the internal audit department can supervise the expenditure in the process of research projects and reduce the waste of resources. Also, it will supervise research management department and project leader to effectively regulate the use of research funds. Therefore, the paper introduces the immune function of internal audit into research funds audit of colleges and universities, to identify, reveal, repair and prevent the problems existing in process of the research activities, so as to improve the efficiency of research funds.

（E-mail:dengxunmaster@163.com, dmr@whut.edu.cn）

Abstract: This paper expounds that the risk conduction of corporate finance system follows the principles of direction, time and intensity. It proposes to plan the risk management prevention and control strategies of corporate financial system from the direction dimension, time dimension and intensity dimension according to those principles. In the aspect of direction dimension, the strategies of preventing and controlling risk conduction through business process chain, interest chain, value chain and capital supply chain was put forward. In terms of time dimension, prevention and control strategies for slowing the release time and speeding from the conduction path are proposed. In terms of intensity dimension, a prevention and control strategies are proposed to reduce the risk of the main body by reducing the degree of strong coupling and transferring risks. This paper has important theoretical research value and practical application value for the prevention and control of risk conduction in corporate finance system.
Key words: Direction dimension; Time dimension; Intensity dimension; 3Dimension prevention and control strategies

1 Introduction

The risks of corporate finance systems are ubiquitous, and they are conducted along business process chains or interest chains or value chains or capital supply chains, leading to varying degrees of damage to stakeholders such as investors, creditors, debtors, tax bureau, and employees. With regard to this, from the perspective of directiondimension, timedimension, and intensitydimension of risk conduction in corporate finance systems,effective prevention and control strategies can be used to quickly, accurately identify financial risks, and control financial risks, and prevent financial risks from so as to protect the interests of enterprises and stakeholders from being infringed andto maintain a stable and sustainable development. However, so far, researches on the prevention and control of risk conduction in corporate finance systems from three-dimensional space are rare. With respect to corporate financial risk conduction, Benston (Benston, 1986) believed that when a certain number of enterprises in a system failed at the same time, systemic risks would occur. Jarrow et al. (Jarrow et al., 2001) conducted a study of corporate financial risk conduction from the perspective of vulnerability. They believed that because one company's failure would lead to failure of other companies, ordinary financial vulnerabilities would arise then. Shen Jun (Shen Jun, 2011), a domestic scholar, studied the direction dimension, time dimension, and intensity dimension of corporate financial risk conduction, and established a prediction model about direction dimension, time dimension, and intensity dimension of corporate financial risk conduction. Based on this, she proposedthe corporate financial risk conduction control model of direction dimension, time dimension, and intensity dimension which had important theoretical research value and practical application value for effective prevention and control of corporate financial system risk conduction.

2 The Structureof 3-dimension Prevention and Control Strategies of Risk Conduction of Corporate Finance System

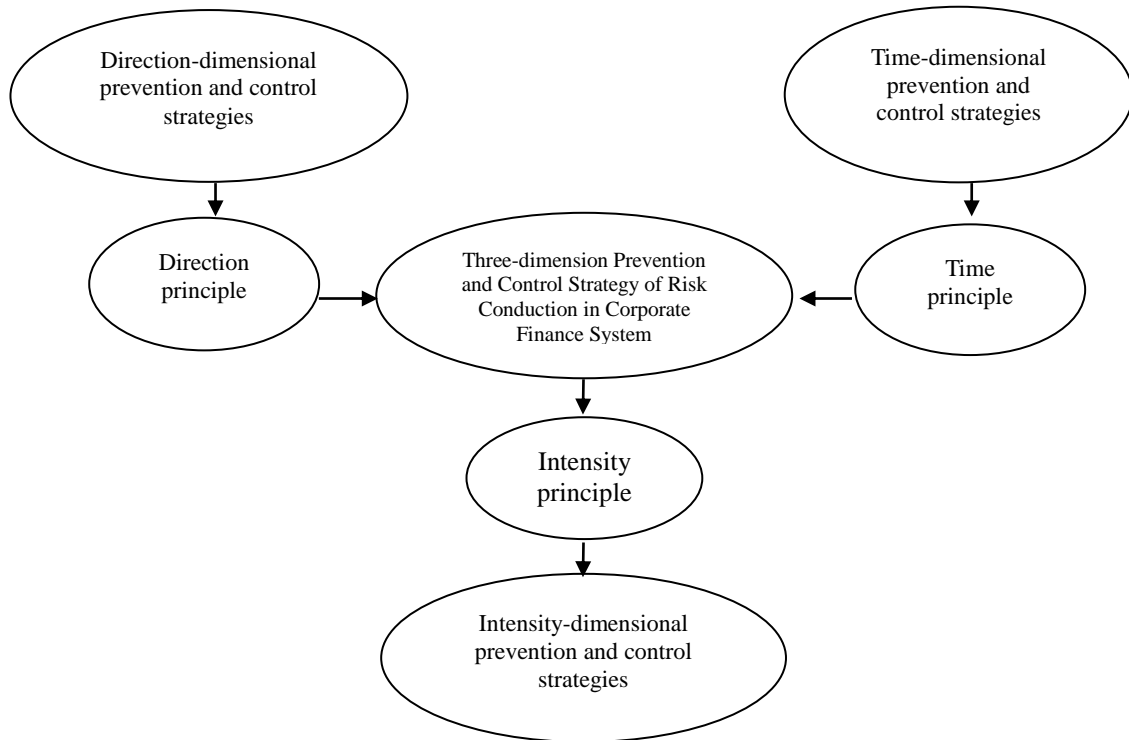
The 3-dimensional prevention and control strategies of corporate finance system risk conduction refers to the direction principle, time principle, and intensity principle of risk communication according to the corporate financial management system. Its prevention and control strategies are planned from the three-dimensional space of direction dimension, time dimension, and intensity dimension, so as to realize the effective prevention and control of risk conduction in financial system. Its concrete structure is shown as in Figure. 1:


Figure 1   Diagram of 3-D prevention and Control Strategies of Risk Conduction in Enterprise Finance Management System

3 Prevention and Control Strategies for Direction-dimensional Risk Conduction of Corporate Finance System

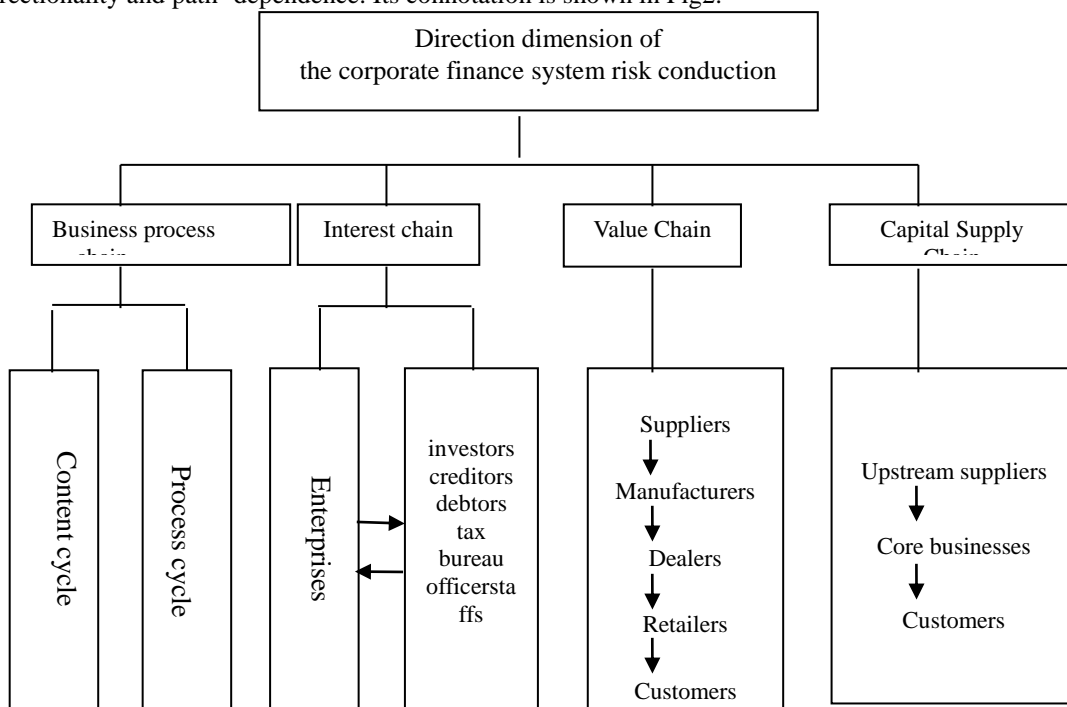
The direction dimension of corporate finance system risk conduction refers to the risk of corporate finance management system is conducted along the business process chain or interest chain, value chain, and capital supply chain of the enterprise financial management system, and presents the features of directionality and path- dependence. Its connotation is shown in Fig2.


Figure 2   Direction Dimensionof Risk Conduction in Corporate Finance System

3.1 Prevention and control strategies for corporate finance system Direction-dimensional risk conductionthrough Business Process Chain

The direction dimension of Corporate Finance System Risk Conduction through business process chain means that risk is transmitted in accordance with the enterprise financial content cycle and process cycle. Its prevention and control strategies mainly include: Firstly,from the government's point of view, to improve accounting laws and regulations, and continuously to strengthen the construction of the financial system. Secondly,from the corporate perspective, to strengthen the control of risk sources such as corporate financing, capital injection, working capital and profit distribution, thus eliminating the risk on the early stage. Thirdly, to promote scientific nature of the operation methods such as enterprise financial forecasting, financial decision-making, financial planning, financial control, financial accounting, and financial analysis, the effectiveness of the execution intensity, and the usefulness of achieving the effect.

3.2 Prevention and control strategies for corporate finance system Direction-dimensional risk conduction through Interest Chain

The direction dimension of Corporate Finance System Risk Conduction through interest chain mainly refers to risk conduction according to the respective economic links between the company and investors, creditors, debtors, tax authorities, and employees. Its prevention and control strategies mainly include: 1 Under the common rules and systems, enterprises and investors clearly define the rights and responsibilities of all parties and balance the interests of all parties; 2 Enterprises and creditors make full use of contract contracts to ensure timely and adequate supply of funds by creditors and the reasonable use of credit terms; 3 In the face of debtors, tax authorities, employees, etc., companies should establish a good corporate image and establish a corporate reputation.

3.3 Prevention and control strategies for corporate finance system Direction-dimensional risk conductionthrough Value Chain

The direction dimension of Corporate Finance System Risk Conduction through value chain mainly refers to the risk that the risk is guided from suppliers to manufacturers, then to retailers, and finally to customers. Its prevention and control strategies mainly include: to prevent control, in-event dynamic control, post-event feedback control among value subjects on the value chain to prevent breaks in the value chain, maintaining healthy operations, and sustainable development.

3.4 Prevention and control strategies for corporate finance system Direction-dimensional risk conduction through Supply Chain

The direction dimension of Corporate Finance System Risk conduction through supply chain mainly refers to the conduction of risk based on capital flows from upstream suppliers to core companies to downstream user. Its prevention and control strategies mainly include: (1) reasonably determining the scale of funds; (2) storing funds in time; (3) ensuring the use of funds; (4) establishing and improving legal supervision.

4 Prevention and Control Strategies for Time-dimensional Risk Conduction of Corporate Finance System

The time dimension of corporate finance system risk conduction refers to the occurrence of intermittent or time-delay or periodic or continuous conduction of corporate finance system risk on the conduction path due to interference, spread and oscillation of related factors. Enterprises can make full use of good time dimension to implement prevention and control of corporate financial system risk conduction. Its prevention and control strategies mainly include:

4.1 Extending the burst time of risks released from the source of risk

The process of risk conduction in corporate finance systems is the process by which risks change from small to large and from quantitative to qualitative. According to the time-based principle of risk accumulation in corporate finance management systems, adopting risk management measures and improving the risk management measures such as risk tolerance of enterprise systems can suppress or reduce the possibility and time that the risk shift from static to dynamic and finally burst out. This strategy enables corporate financial system risk to be resolved before it has impacted the business, and it will provide time for the company to cope with the risk conduction of financial systems.

4.2 Extending the burst time of risks released from the source of risk

The process of risk conduction in corporate finance systems is the process by which risks change from small to large and from quantitative to qualitative. According to the time-based principle of risk accumulation in corporate finance management systems, adopting risk management measures and

improving the risk management measures such as risk tolerance of enterprise systems can suppress or reduce the possibility and time that the risk shift from static to dynamic and finally burst out. This strategy enables corporate financial system risk to be resolved before it has impacted the business, and it will provide time for the company to cope with the risk conduction of financial systems.

4.3 Reducing the speed of risk conduction of corporate financial system

The faster the corporate financial system's risk conduction speed is, the shorter the time it takes for the risk to be on the conduction path, and the greater the loss to the relevant parties in the chain. By increasing the damping of risk conduction in corporate finance systems or mitigating the intensity of risk drivers and extending the distance of risk conduction paths, companies can delay the conduction of risk management in corporate finance systems The risk management and early warning system of corporate wealth management system can be used to take effective measures to resist or prevent the intrusion of risks, mitigate the speed of risk conduction and make early plans for risk prevention and control when the risks corporate wealth management systems real or potential the company is facing have not yet emerged or have just been exposed.

4.4 Establishing Information Conduction Mechanism on the Benefit Chain

In the interest-based financial relationship network, accurate, real, timely information communication is critical to block corporate finance system risk conduction. Enterprises can control the occurrence of corporate financial system risks by adopting parallel management of risk conduction carriers such as information flow, capital flow, and logistics, and establishing a sound financial mechanism for each member unit of the interest chain. Through this method, enterprises can track and control in real time and get feedback in time, thus ensuring the safe and efficient operation of the entire interest chain.

5 Prevention and Control Strategiesfor Intensity-dimensional Risk Conduction of Corporate Finance System

The intensity dimension of Corporate Finance System Risk Conduction mainly refers to the phenomenon that various single-factor risks of the corporate financial system encounter each other in the risk conduction path, and they may be weakly coupled or strongly coupled, resulting in exhausted risk conduction or enhanced risk conduction. Its prevention and control strategies mainly include:

5.1 Reduce the degree of strong risk coupling in corporate finance system and avoid enhanced risk conduction

In the process of production and business activities of the company, various single-factor financial risks occur at the same time, and the interplay of these different attribute risks will inevitably produce strong coupling effects. At this time, the company should strengthen the independent operational capabilities of various functional nodes, regulate the conduction of various risks and effectively control the key elements of risk conduction, try to control the convergence or intertwining of the risk factors of each single factor so as to minimize the risk-strong coupling phenomenon. To prevent enhanced risk conduction.

5.2 Leading the risk management of corporate finance system to other conduction entities, spreading risks and creating exhausted risk conduction

There is objectivity in the risk conduction of corporate finance systems, and there is also subjectivity. Objectivity refers to the risk conduction of corporate financial system is not based on the will of the people, which inevitably has an adverse impact on the corporate financial management system; subjectivity refers to that the enterprise managers can actively guide the risk to the other risk-taking subjects through human intervention and conduction to achieve the purpose of spreading risk and reducing the intensity of risk coupling. The main ways are:

(1) Insurance

Insurance means that by paying premiums, the insured party has the right to indemnify the insured party against the insured's economic losses within the scope specified by the contract and the law. According to the insurance contract, the damaged enterprise has the right to obtain corresponding economic compensation from the insurance company, thereby helping the enterprise to restore normal production and business activities in time and improve the financial stability of the enterprise.

(2) Outsourcing

Outsourcing means that the company outsources its non-core business to other companies and seeks resources from the outside, thereby conduction quality risks, capital occupation risks, and technical risks to outsource, thereby reducing their own risks and enhancing the ability to resist risks.

(3) Selling

Selling refers to the conduction of ownership from the seller to the buyer through the sale of the company, so that the buyer company bears all risks to the entity. In this way, the seller's company can eliminate operational problems, quickly recover funds, and rationally allocate resources to open up new business areas so as to achieve the purpose of conduction risks.

6 Conclusion

The risk conduction of corporate financial system follows the principles of direction, time and intensity. Based on these basic principles, three-dimensional prevention and control strategies for direction dimension, time dimension, and intensity dimension can be formulated which have their pertinence, operation, and scientity, so as to achieve the effectiveness of prevention and control of risk conduction in corporate financial systems.

(1) Direction-dimensional risk prevention and control strategies of corporate finance system mainly include developingoperation strategies from the three directions of business process chain direction, interest chain direction, value chain direction and capital supply chain direction. so as to achieve the goal of risk prevention and control.

(2) Time-dimensional risk conduction prevention and control strategies of corporate finance system mainly includes measures to delay the time of risk release and the speed of conduction and establish Information conduction mechanism by following the time law that corporate financial system risk is transmitted from the risk source to the risk acceptor so as to cope with financial system risk conduction and prevent and control risk conduction effectively.

(3) Intensity-dimensional prevention and control strategies of risk conduction in corporate finance system mainly includes: (1) Take effective measures against all kinds of single-factor financial risks that may occur during the production and business activities of the enterprise, avoiding the aggregation or intertwining of various risks, and thus reducing the coupling effect to minimum degree; (2) Through the business methods of insurance, business outsourcing, and sales, guide the risk management of the corporate finance system to other conduction entities, diversify risk, and thus achieve prevention and control of risk conduction.

Assessment of Emergency Logistics Risk Based on Structural Equation Model

Liu Yixuan, Ye Can, Liu Xuan
School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: jasonlewes@whut.edu.cn, yecan@whut.edu.cn, 760028239@whut.edu.cn)

Abstract: Natural disasters and other emergencies have caused serious economic and social losses. Emergency management can control losseseffectively. Emergency logistics is an important part of emergency management. On the basis of understanding the characteristics and application scenarios of emergency logistics, this paper constructs a risk assessment system for emergency logistics through literature learning. The structural equation model was used to evaluate the impact of various risk factors on the overall risk and the correlation between risk factors. The results of the study show that, purchaserisk of emergency materials, reserve risk of emergency materials, transportation of emergency materials, political and organizational risk, informational and social risk have significantly positive impacts on the overall risk of emergency logistics.
Key words: Emergency logistics; Risk assessment; Structural equation model; Literature review

1 Introduction

Natural disasters and emergencies are often difficult to predict and forecast. Even if some disasters can be forecasted, due to the short interval between the forecasting time and the time of occurrence, emergency materials for disaster relief are difficult to achieve their time and space effects, making it difficult to implement their logistics process. Therefore, the study of emergency logistics management has become an important issue in social security (Zhou Yu, 2009).

In recent years, many scholars have achieved innovative and effective results in this field.Song Yinghua (Song Yinghua, 2018) constructed a two-layer dynamic LAP model in view of the severe shortage of emergency materials in the disaster area in the aftermath of earthquake so as to meet the different emergency needs of multiple subjects. Emre Kirac, Ashlea Bennett Milburn(Emre Kirac, Ashlea Bennett Milburn, 2018) presented a general framework for investigating whether it is worthwhile to act on user-generated data prior to its absolute verification in the context of disaster response logistics planning. Alfredo Moreno (Alfredo Moreno, 2016) developed two stochastic mixedinteger programming models to integrate and coordinate facility location, transportation and fleet sizing decisions. Min Peng (Min Peng, 2014) proposed a system dynamics model to analyze the behaviors of disrupted disaster relief supply chain by simulating the uncertainties associated with predicting post-seismic road network and delayed information.Wang Haijun, Ma Shihua, Du Lijing (Wang Haijun, Ma Shihua, Du Lijing, 2014) studied the dynamic scheduling of emergency materials for multi-modal joint transportation under fuzzy supply and demand conditions, focusing on the characteristics of large-scale emergency response. Under the efforts of many scholars, emergency logistics has formed a complete theoretical system.

Emergency logistics, as a system engineering, involves the external constraintsof policy environmentand natural environment, and the internal limitations of institutional mechanisms and emergency resources. At the same time, it involves the game between different subjects such as government, demand side, supply side, transporters, and volunteers. When the rules of the exchange of material, energy, and information between the emergency logistics system and the outside world are broken, the risk energy originally contained in the operation process will be released and followed by a certain chain of risk evolution, and eventually evolved into a risk loss. From the perspective of logistics operations in the handling of various emergencies in recent years, effective implementation of risk management in the process has become one of the keys to the success of emergency logistics. Strengthening emergency logistics risk analysis and evaluation is an urgent need for the change of the situation, and it is also an important issue to China's current development of emergency logistics. In recent years, some scholars have begun to study the uncertainty of emergency logistics and sought to minimize its risk.

Table 1   Results of Emergency Logistics Risk Research

Scholars	Reseach
Mei-siang	Meisiang proposed that government logistics should be used to deal with emergency logistics problems caused by floods in the uncertain situation.
Li Jingyi	Pointed out that GIS plays an important role in emergency logistics management; at the same time, it puts forward application of GIS in the four stages of emergency logistics management: risk assessment and planning phase, preparation phase, response phase and recovery phase.
Zhao Yong	Systematically analyzed the features of emergency logistics and the characteristics of emergency logistics risks, and proposed a framework model for emergency logistics risk analysis, namely the three processes of emergency logistics risk identification, risk assessment and risk rating.
Li Jianguo	Applied the Analytic Hierarchy Process (AHP) to evaluate the support capabilities of emergency logistics and tried to establish a method to evaluate it.
Xia Caiyun	Used the theory of interval number to study the problem of minimizing the risk of selecting transportation route after the occurrence of an emergency event, providing a strong basis for risk control and route selection.

Previous researches in this field have provided us with important theoretical references and practical experiences. However, at present, there are still two deficiencies in the study of emergency logistics. First, quantitative research basically adopts the methods in optimization method and simulation method in operations research, and does not apply the statistical method to analyze the relationships among the elements of the emergency logistics system. Second, it pays too much attention to the logistics optimization under emergencies, and less attention to the uncertainties faced by the emergency logistics as a system engineering. This article will comprehensively identify and evaluate risks of emergency logistics based on extensive literature retrieval and theoretical learning.

2 Risk Evaluation Index System of Emergency Logistics

The design of the risk evaluation index system of emergency logistics needs to identify the source of risk first. According to the foregoing analysis, the source of emergency logistics risks is contained in the internal and external environmental changes brought about by unexpected events. The risk indicators can be designed based on the operational flow of emergency logistics and divided into direct and indirect process risk. The direct operation process is a collection of internal factors that cause emergency logistics risk, including the three major risk sources. They are purchase risk of emergency materials, reserve risk of emergency materials, and transport risk of emergency materials. The indirect operation process is the collection of external factors that cause emergency logistics risks, including political and organizational risk, informational and social risk. They are two major source of indirect risk. According to the characteristics of the emergency logistics risk, the risk source can be further subdivided, and the indicator system can be set up as the following first-level indicators: purchase risk of emergency materials, reserve risk of emergency materials, transport risk emergency materials, political and organizational risk, informational and social risk. Each first-level indicator can be further subdivided into a number of secondary and tertiary indicators. Based on this, we propose the hypotheses of this paper:

H_1: Purchase risk of emergency materials, reserve risk ofemergency materials, transport risk of emergency materials, political and organizational risk, informational and social risk have a significantly positive impact on the overall risk of emergency logistics. H_2: Supplier production capacity,suppliers' ethics, quality of emergency supplies, the complexity of sources of emergency materials, timeliness of delivery of emergency materials have a significantly positive impact on the purchase risk of emergency logistics. H_3: Rationality of the layout of reserve centers, reserve of emergency materials, reserve of emergency fund have a significantly positive impact on the reserve riskof emergency materials. H_4: Degree of damage to transport channels, accessibility of disaster areas, rationality of the layout of the traffic network, rationality of layout of emergency logistics center, rationality of transportation vehicleshas a significantly positive impact on the transport risk of emergency materials. H_5: Coordination between administrations, completeness of strategic emergency warning mechanism, correctness of emergency management decisions, professional quality of emergency logistics personnel, number of emergency logistics personnel have a significantly positive impact on political and organizational risk. H_6: Government's cohesion, stability of communication system, social sentiment, completeness of DSS of emergency logistics have a significantly positive impact on informational and social risks. H_7: There are correlations between the five latent variables of purchase risk of emergency

materials, reserve risk of emergency materials, transport risk of emergency materials, political and organizational risk, and informational and social risk that affect the overall risk of emergency logistics.

Table 2　Emergency Logistics Risk Assessment Index System

Source of risk	Risk factors	Coding
Purchase risk of emergency materials (R_1)	Suppliers' production capacity	R_{11}
	Suppliers' ethics	R_{12}
	Quality of emergency supplies	R_{13}
	The complexity of sources of emergency materials	R_{14}
	Timeliness of delivery of emergency materials	R_{15}
Reserve risk of emergency materials (R_2)	Rationality of the layout of reserve centers	R_{21}
	Reserve of emergency materials	R_{22}
	Reserve of emergency fund	R_{23}
Transportation risk of emergency materials (R_3)	Degree of damage to transport channels	R_{31}
	Accessibility of disaster areas	R_{32}
	Rationality of the layout of the traffic network	R_{33}
	Rationality of layout of emergency logistics center	R_{34}
	Rationality of transportation vehicles	R_{35}
Political and organizational risk (R_4)	Coordination between administrations	R_{41}
	Completeness of strategic emergency warning mechanism	R_{42}
	Correctness of emergency management decisions	R_{43}
	Professional quality of emergency logistics personnel	R_{44}
	Number of emergency logistics personnel	R_{45}
Informational and social risk (R_5)	Government's cohesion	R_{51}
	Stability of communication system	R_{52}
	Social sentiment	R_{53}
	Completeness of DSS of emergency logistics	R_{54}

3 Risk Assessment Based on Structural Equation Model

3.1 Selection of models and methods

The SEM establishes a causal model to observe causal relationships between variables. SEM is divided into measurement model and structural model: (1) Measurement equation describes the relationship between latent variables and observed variables. Observation variables obtain the intuitive data through the scale or other measurement tools. (2) Structural equations describe the relationship between latent variables. Exogenous latent variables refer to latent variables as causal factors, and endogenous latent variables are latent variables that can act as outcomes.

The measurement equation is expressed as:

$$Y = \Lambda y n + \varepsilon \tag{1}$$

In the above model, X is the observed variable of ξ, Y is the observed variable of η, ξ and η are exogenous latent variables and endogenous latent variables. Λx and Λy are the relationships between latent variables and observed variables respectively, which is factor load matrix. δ and ε are the errors of the X and Y variables respectively.

The structural equation is expressed as:

$$\eta = B\eta + \Gamma \xi + \varepsilon \tag{2}$$

In the above model, η indicates endogenous latent variables, ξ indicates endogenous latent variables, B is the relationship between endogenous latent variables.

3.2 Data collection and empirical test

This paper adopts 5-point Likert scale to measure the attitudes of theoretical experts in universities,

practice experts on emergency management and other relevant personnel. The degree of each risk indicator'simpact is scored, and the overall risk is scored. Finally, the acquired data is substituted into the structural equation model for hypothesis testing. This paper selects the staff of the logistics company in Z city of H province, logistics management and emergency management researchers and the students of major universities as samples, and distributes a total of 281 questionnaires.

This paper uses statistical software SPSS 23.0 to analyze the reliability and validity of the emergency logistics risk scale. (1) Reliability test. Cronbach's α reliability coefficient is used to check the internal consistency and stability of the scale, which is between 0-1. The larger the α value, the higher the data reliability. The overall reliability of the scale was 0.964, and the Cronbach's α values of the measured variables met the critical conditions of greater than 0.7 and were all above 0.9. The correlation coefficient between the revised item and the total is above 0.5. Only the CITC value of the variable R_{51} does not reach 0.5, and the overall reliability is improved after the deletion, so the indicator is removed. (2) Validity test. The load values of various factors and the KMO sample measure and the Bartlett sphericity were used to test the validity of the data. The KMO value was 0.953, which was above 0.9. The Bartlett's spherical test Sig. was 0.000<0.005. The questionnaire had good validity and was very suitable for factor analysis.
Figure 1   Structural equation model path diagram

Table 3   Model Fit Test Results

Index classification	Index name	Model fitting value	Critical value	Fit evaluation
Absolute fit indicator	X^2/DF	2.783	<5	Ideal
	RMSEA	0.076	<0.08	Ideal
	GFI	0.923	>0.9	Ideal
	AGFI	0.897	>0.9	Acceptable
Value-added adaptation indicator	NFI	0.951	>0.9	Ideal
	RFI	0.931	>0.9	Ideal
	IFI	0.944	>0.9	Ideal
	CFI	0.899	>0.9	Acceptable
Simplified fitting index	PGFI	0.491	>0.5	Acceptable
	PNFI	0.706	>0.5	Ideal
	PCFI	0.716	>0.5	Ideal

Table 4   Hypothesis Test

Latent variable	Path	Observation Variable	Influence direction	Path coefficient	S.E.	T	P	Test result
Risk	←	R1	+	0.401	0.025	4.091	***	Pass
Risk	←	R2	+	0.440	0.014	2.827	***	Pass
Risk	←	R3	+	0.571	0.019	3.670	***	Pass
Risk	←	R4	+	0.330	0.025	2.847	***	Pass
Risk	←	R5	+	0.549	0.021	2.314	***	Pass

As is shown in the above table, the test of hypotheses about the impact of each risk source on the overall risk of emergency logistics have passed. This result provides an important reference for macro-management and decision-making of emergency logistics from the government level. At the same time, H_7 also passed the test, indicatingthat the five major risk sources act on the overall risk of emergency logistics in the impact of collaborative interaction. When establishing a risk prevention and control mechanism, we should stand in the perspective of a dynamic, open, and balanced system, considering the adaptation between macro and micro environments and the coordination of interests between multi-agent. Due to space limitations, the testing results of correlation of each risk source are not shown in the main text, and can be requested from the author.

4 Conclusion

Although based on extensive research, this paper has carried out a more systematic identification and evaluation of emergency logistics risks, but there are still some limitations and deficiencies: (1) There are limitations in sample selection and sample size. The number of entities that are directly related to emergency logistics is limited, and due to some objective factors, it is not possible to select samples for investigation in a wider range. (2) The composition of evaluation indicators has limitations. Although this article systematically builds a risk assessment system from different dimensions, it has a large number of subjective indicators and the objectivity in risk assessment is insufficient. (3) The empirical analysis has limitations. This paper evaluates the attitude measurement data of the Likert scale so that the subjectivity is strong.

In the future research, amendments to evaluation indicators should be incorporated into local economic statistics and past cases of emergency logistics to increase the objectivity of evaluation results. As far as funding is allowed, relevant entities in all areas where the incident occurred should be investigated to increase the accuracy of sample selection. We can build dynamic risk assessment indicators, using grounded theory to identify risks, combining emergency logistics processes, stakeholders, internal and external environments, so as to judge critical risk points, analyze risk evolution mechanisms, and dynamically monitor risk evolution.We can also use big data technology to build early warning and risk prevention platform, effectively prevent and control the risk of emergency logistics.

Evaluation and Innovation Strategy for the Key Points of Coping Mechanismon the "NIMBY" Event in Garbage Incineration Power Generation

Liu Enyuan

School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070

(Email: 1789725697@qq.com)

Abstract: As a waste disposal method of "reducing, harmlessness, and resource recovery", the garbage incineration power generation has aroused great attention of the state. But in the course of advancing the project, it is facing the difficulty of landing caused by the "NIMBY" event. This paper uses web crawler technology, natural language processing technology and entropy value method evaluation model, obtains the important factors which affects the landing of the city garbage incineration project, proposes the effective methods and provides the decision-making basis for the emergency management of garbage incineration power generation.

Key words: Garbage incineration; NIMBY; Entropy; Erases management

1 Introduction

According to the 2016 China Rule of law Development Report statistics, in recent years, mass incidents involving more than one hundred people in China, about 32% are closely related with the garbage incineration such as "NIMBY" project, particularly serious such as Hubei Xiantao, Zhejiang Yuhang, Beijing six-Li Tun, Gao An Tun, Asu Wei, Shanghai Jiang Qiao, Songjiang, Guangzhou Panyu and other social security incidents. However, with the continuous development of our society and the increasing level of urbanization, the rapid growth of urban population has led to the increasing of urban waste production and the volume of clearing. At present, more than two-thirds of the cities in China are beset by rubbish siege, and the garbage incineration power generation, as a waste disposal method of "reducing, harmlessness and resource recovery", has aroused great attention of the state. However, in the process of the garbage incineration power generation project, it has been plagued by the "NIMBY" incident.

The foreign scholars had an earlier study of "NIMBY". In 2016, E. Pol, A. Dimasso and others used the case statistics method to investigate the construction of the "NIMBY" facility which was found in the European region for 15 years since 1999, found that the "NIMBY " phenomenon is related to the regional population ideology (E. Pol, etc., 2006). In 2010, with the survey methods of in-depth interview, group discussion and questionnaire, Patrick Devine-Wright and Yuko Howes found that the main cause of the conflict between the construction of wind power plants is "The public lack of contact and understanding of the project " (Patrick Devine-Wright,YukoHowes, 2010).

Chinese scholars' study on the "NIMBY" incident was relatively late. In 2013 Yang Yi and Zhu Hong used literature analysis, field observation and semi-structured interview methods to study the INMBY attitude of the common people lived nearby the garbage incineration power plant in Guangzhou panyu. It was found that "spatial distance and social economic characteristics have great influence on the attitude of NIMBY of people" (Yang Jin, Zhu Hong, 2013). In 2016, Song Jinbo, Song Danrong and Sun Yan used a case study to analyze the key risks of a garbage incineration project and find that "government decisions, technology, operations, and garbage supply are key risks in the advancement of wasting incineration projects (Song Jinbo, Song Danrong, Sun Yan, 2012)".

To sum up, the domestic and foreign scholars on the "NIMBY" event research generally using questionnaires and case analysis methods.Most of them only researched for one or several cases and they were lack of a more macroscopic quantitative analysis.What's more, they rarely mentioned the more comprehensive system mechanism innovation either. In view of the above problems, this paper adopts the method of quantifying the case key words, through the quantitative analysis of the typical cases, obtains the important factor that causes the conflict of the garbage incineration power generation project "NIMBY", and puts forward the innovative mechanism to resolve the conflict of "NIMBY" of refuse incineration.

2 NIMBY Event Keyword Analysis

2.1 NIMBY event innovation processing technology

In the past, the basic means of dealing with "NIMBY" event include literature analysis, case reasoning and specific model analysis, compared with the previous qualitative research methods in China, this research is based on the framework of "theoretical research + semantic analysis + case Inference", and comprehensively utilizes web crawler technology. , natural language processing, word segmentation method, theory literature, probability analysis and so on, formed the "NIMBY" event innovation mechanism.

2.2 Keyword capture process

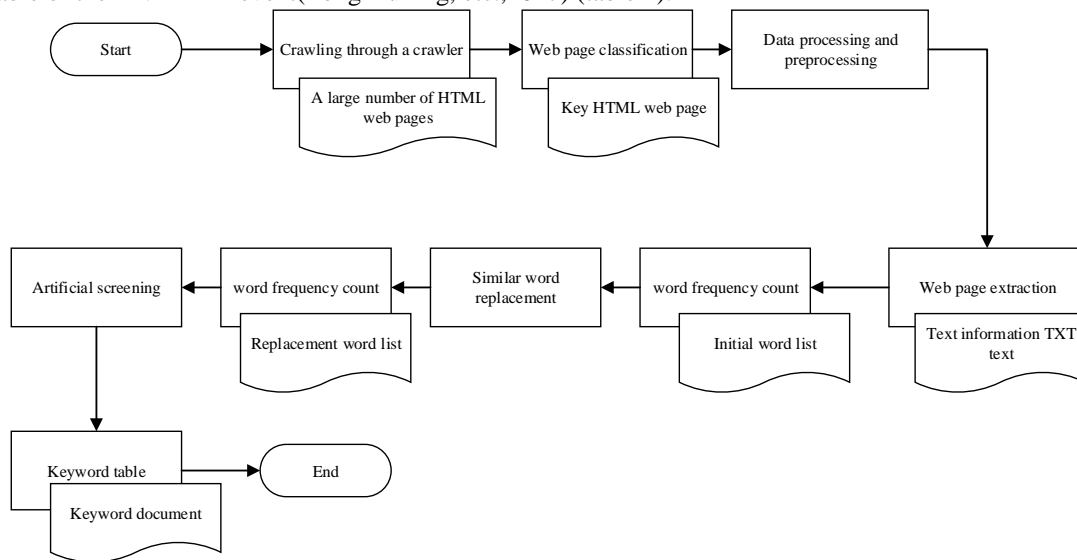
Processing process as shown in the Figure 1, to aim at the more decentralized distribution features of the garbage incineration power generation "NIMBY" event on the Internet, I designed through the link tag on the Internet to crawl the content of the general crawler. According to the crawling and grasping contents of the crawler, the paper makes a double screening and finally obtains the webpage file of the key page with high relevance to the study by the filtering algorithm of HTML structure designed for the text structure. At the same time, using the machine learning of natural language processing (NLP) Technology of Chinese word segmentation, lexical similarity analysis and calculation of the two main analytical methods, combined with artificial assistance analysis, obtained the keywords table of the " NIMBY" event(Zong Huiling, etc.,2017) (table 1).


Figure 1   Keyword Processing Process

Table 1   "NIMBY" Event Keywords Table

Keywords table				
Living Garbage	Residents	site selection	Government	Emission standards
Participation	Information disclosure	Supervision	Dioxin	Risk
Pollution	environmental quality assessment	Landfill	Conflict	Opinion
Protest	Compensation	Consultation	Solicit comments	Trust

2.3 Keyword processing results

The key cases were obtained by vectorization of the key words and the corresponding weights, and the table 2is obtained.

Table 2   "NIMBY" Event Case to Quantification

	Living Garbage	Residents	site selection	Government	…	Compensation	Consultation	Solicit comments	Trust
1	0.7455	0.2485	0.0497	0.5964	…	0.0248	0	0	0
2	0.1751	0.0729	0.0145	0.9778	…	0	0	0	0
3	0.4668	0.5189	0.0781	0.6752	…	0.0200	0.0080	0.0060	0.0360
4	0.4319	0.4297	0.3284	0.6637	…	0.0427	0.0045	0.0067	0.0045
5	0.8222	0.2740	0	0.1796	…	0	0.0685	0	0

Continual Table 2

	Living Garbage	Residents	site selection	Government	…	Compensation	Consultation	Solicit comments	Trust
…	…	…	…	…	…	…	…	…	…
24	0.3642	0.2649	0.1986	0.8609	…	0	0	0	0
25	0.6173	0.0809	0.0708	0.7489	…	0	0	0	0
26	0.7287	0.3729	0.0573	0.4992	…	0.0172	0	0	0.0057
27	0.2797	0.2272	0.2272	0.8041	…	0.0174	0	0.5244	0
28	0.6829	0.2897	0	0.6001	…	0	0.0620	0	0

The horizontal expression in the table is the key word of the "NIMBY" event, and the longitudinal word is the proportion of the key word in the corresponding case.

3 Research Methods and Results Analysis

3.1 Entropy value method evaluation model

The entropy method is a method of determining weights according to the difference degree of the index data between each scheme (sample) (Wang Yuan, etc., 2013). If the data of each scheme (sample) is very different, the index's weight is heavy. The projection process is divided into three steps:

The first step is to convert the standard data y_{ij} to a specific gravity P_{ij}.

$$P_{ij} = \frac{y_{ij}}{\sum\limits_{j=1}^{n} y_{ij}}, (i = 1, 2...m; j = 1, 2....n)$$

The second step is to calculate the entropy value of each indicator e_i.

$$e_i = -K \sum\limits_{j=1}^{n} P_{ij} \ln(P_{ij}), (i = 1, 2...m) \text{ (where k=1/lnn)}$$

The third step is to calculate the weight w_i

From the above, the smaller the data difference for indicator i, the greater the e_i is, and the greater the data difference, the smaller the e_i is. On the other hand, if the data of indicator i is large, it indicates that the action of the Scheme (sample) is large and its weight should be larger; on the contrary, the weight should be smaller. Therefore, the weight and the entropy value should be complementary relations, namely

$w_i' = H - e_i$, the full score of the scheme (sample) is the product of the H and the sample size.

Normalized treatment, obtained:

$$w_i = \frac{w_i'}{\sum\limits_{i=1}^{m} w_i'}, (i = 1, 2...m)$$

3.2 Evaluation results analysis

The transverse of the table is the key word of "nimby" event, and the longitudinal is the entropy value of the keyword in the typical case and the weight that is converted according to the entropy value.

Table 3   "NIMBY" Event Keyword Weight Table

Keywords	Trust	Dioxin	Conflict	Solicit comments	Consultation	Compensation	environmental quality assessment	Opinion	Landfill	Supervision
Entropy value	0.1149	0.2155	0.2608	0.2742	0.3363	0.4037	0.6005	0.6624	0.8732	0.8904
Weight	0.0739	0.0714	0.0702	0.0698	0.0683	0.0665	0.0615	0.0599	0.0545	0.0540

Keywords	Protest	Risk	Information disclosure	Participation	Emission standards	site selection	Pollution	Government	Living Garbage	Residents
Entropy value	0.9281	1.1697	1.3131	1.3902	1.3914	1.4102	1.5187	2.0398	2.3639	2.8457
Weight	0.0531	0.0469	0.0432	0.0412	0.0412	0.0407	0.0379	0.0246	0.0163	0.0039

It can be concluded from the data analysis in the table that the key words such as trust, negotiation and compensation(HeYi, Zhao Zhijie,2013, Zhu Yangguang,Yang Jie,Zou Liping,2014, Guan Zai-gao,2010) have a large weight and influence in the "NIMBY" event. However, the key words such as emission standard, site selection and pollution have less weight in the "NIMBY" event and therefore less influence. The two key words, trust and compensation, can be analyzed by natural language technology, which is the key factor of "NIMBY" conflict. In addition, the government, residents of the two representatives of the "NIMBY" event main body of the key word entropy value is larger. It can be inferred that the two are the core of the conflict between "NIMBY"(Gao Jun-bo, etc.,2016). Combined with the above analysis, through the comprehensive inference can be drawn, leading to the "NIMBY" incident, the main reason for the difficult landing of garbage incineration projects is the poor information communication and imbalance of interest distribution caused a public crisis of confidence in the government.

This paper puts forward two mechanism innovations by considering the causes of "NIMBY" and taking full account of the two core subjects of the "NIMBY" incident, in order to avoid the "NIMBY" conflict, to maintain social stability and harmony, and to "NIMBY" as "neighbor benefit".

1) Strengthen the information communication, improve the benefit coordination and consultation democratic mechanism of project argumentation

The government should do a good job in selecting a scientific site, listen to people's opinions in time, do more communication, cooperate more, negotiate more, coordinate the interests of many parties and achieve a win-win situation.

2) Careful planning, improve the multiple compensation guarantee mechanism

The government should adhere to the "who benefits, who compensation" principle, the establishment of a loss quantification system, to achieve accurate compensation, while the establishment of entertainment, capital, medical, ecological compensation mechanism, to make up for the psychological deviation of the people.

4 Conclusion

As a great project of the benefit of the nation, the garbage incineration power generation project has always been plagued by the "NIMBY" incident. To solve the problem of "NIMBY", we should take a new angle to analyze the problem of "NIMBY", and make the "NIMBY"to benefit between neighbors.In this paper, we use the entropy method to analyze the characteristics of the typical cases of Internet crawl, to explore the factors affecting the "NIMBY" problem of the garbage incineration power generation, and propose the innovation mechanism to provide the theoretical basis for the effective decision.

(E-mail: 526835339@qq.com, 455502387@qq.com)

Abstract: Local government debt risk is a severe issue in China. By learning and referring from the predecessors in the relevant research, this paper selects first-level indexes and second-level indexes.They can reflect local government debt risk. Then we build the evaluation index system for local government debt risk in China based on analytic hierarchy process (AHP). Adopting the evaluation system, we make an empirical study on the local government debt risk of 15 provinces in China in 2016. Finally, we put forward countermeasures and suggestions.
Key words: Analytic Hierarchy Process (AHP); Local government debt risk; Evaluation index; Region analysis

1 Introduction

In March 2018, the report on the Work of the Government in two sessions of the NPC and CPPCC puts forward preventing and resolving major risk. And the local government debt risk is about preventing and resolving major risks. But China government lacks a comprehensive, systematic and concise evaluation index system for local government debt risk. It needs detailed suggestions and countermeasures forlocal government debt risk.

In the evaluation of local government debt risk, the domestic and foreign academia's dominant practice is to extract the indexes which affects the local debt risk firstly. Some scholars are according to the classification of debt types (XieHong, 2007) or the types of risks (XuLei, LiuXiaochuan, 2018) and so on. In addition, they are likely to adopt objective weighting method to make the conclusions, such as Entropy Valueto. Because it's with strong mathematical theory (Diao Weitao, 2017). But to some extent, that doesn't reflect the importance of the judges on different indexes. In consideration of the disadvantages of the predecessors' methods, the paper eliminates the repetitions or unrepresentative factors, chooses from the causes of local government debt, the source of local government debt repayment and the classification of local government debt risk to establish the evaluation index system.From three dimensions(local economic development, financial situation and debt situation), the system adopts subjective weighting method, analytic hierarchy process(AHP). After that, the paper makes an empirical analysis of 15 provinces in China in 2016 according to the economic regions. Then this paper put forward regional countermeasures and suggestions for the prevention and resolution of local government debt risk. We expect it can provide reference for local governments to carry out local government risk evaluation and prevention.

2 Extraction of the Evaluation Indexes for Local Government Debt Risk in China

2.1 Selection of the factors affecting the local government debt risk

2.1.1 Causes of local government debt

One of the main reasons leadingtodebt is that the local economy needs the support of the local finance, but the financial resources can't support it. So, the local government must raise money, which creates the debt. In other words, the local economy, the government finance and the debt correlate to each other.

2.1.2 Source of repayment of local government debt

The repayment is vital to local government debt. Local finance is a direct source of local government debt payment, so local financial situation has a direct impact on local government debt risk. Besides, the economic development decides the government finance. So, the local economy has an indirect but fundamental effect on the local government debt.

2.1.3 Classification of local government debt risk

Local government debt risk includes scale risk and structural risk. Scale risk refers that local debt is too large to be repaid. Structural risk isn't considered due to the closed statistics. So, local government debt situation has an impact on local government debt risk.

2.1.4 Summary of the Factors Affecting the Local Government Debt Risk

Local economic development and local financial situation negatively affects local government debt risk, while local government debt situation positively affects the debt risk. Therefore, local economic development and local financial situationis extracted as the first level negative indexes, and local government debt situation as the first level positive index.

2.2 Selection of the second level index

2.2.1 Second level indexes to indicate local economic development

When evaluating the current economic development in a regionandcomparing the situation of different religions, real GDP per capita is usually selected as the secondary index to reflect the local economic development, and GDP growth is selected to assess its long-term economic development.

2.2.2 Second level indexes to indicate local financial situation

The paper selects the ratio of financial revenue and expenditure and theelastic coefficient ofgovernment receipts as the second level indexes to indicate local financial situation.The former indicates the current financial situation. The latter reflects the prospect of local financial situation.

2.2.3 Second level indexes to indicate local government debt situation

Debt balance is the direct reflection of the scale of local government debt, so debt per capita is selected as the secondary index. Besides, too much debt is due to the current debt beyond the current government debt paying ability. Therefore, debt-to-GDP and debt-to-government receipts are selected as the second level indexes.

Table 1 Evaluation Index System for Local Government Debt Risk

First-Level index	Second-Level index	Index meaning	Index attribute
Local economic development	Real GDP per capita	Real GDP / Population	Negative
	GDP growth	(Current GDP-Previous GDP) / Previous GDP	Negative
Local financial situation	Ratio of financial revenue and expenditure	Financial revenue / Financial expenditure	Negative
	Elastic coefficient of government receipts	Government receipts growth / GDP growth	Negative
Local government debt situation	Debt-to-GDP	Debt balance / Real GDP	Positive
	Debt per capita	Debt balance / Population	Positive
	Debt-to- government receipts	Debt balance / Government receipts	Positive

3 Construction of the Evaluation Indexes for local government debt risk in China

3.1 Determination of index weight by AHP

In the help of ten professors and government clerks, we assess the index by the following 1-9 scale.

Table 2 T.L. Saaty The Fundamental Scale of Absolute Numbers

Intensity of importance	Definition
1	Equal importance
2	Weak or slight
3	Moderate importance
4	Moderate plus
5	Strong importance
6	Strong plus
7	Very strong or demonstrated importance
8	Very, very strong
9	Extreme importance

3.1.1 Number the index

Number the local economic development as a_1, the local financial situation as a_2, and local the government debt situation as a_3.

3.1.2 Build the judgment matrix

By the evaluation of the indexes from ten professors and government clerks, we build the matrix.

$$A = \begin{bmatrix} 1 & 2 & 3 \\ 1/2 & 1 & 4 \\ 1/3 & 1/4 & 1 \end{bmatrix} \tag{1}$$

3.1.3 Consistency check

It has been calculated that its largest eigenvalue is 3.1078 (i.e. λmax=3.1078).

$$CI = \frac{\lambda max - n}{n-1} = \frac{3.1078 - 3}{3-1} = 0.0593, \ RI = 0.5 \tag{2}$$

$$CR = \frac{CI}{RI} = \frac{0.0593}{0.58} = 0.093 < 0.1 \tag{3}$$

Therefore, the judgment matrix has passed the consistency test.

3.1.4 Calculate the weight by combination weight vector

Finally, by calculation we can know the combination weight vector: ω=(0.622，0.213，0.165)^T. It means that the weight of local economic development is 0.622, the weight of local financial situation is 0.213, and the weight of Local government debt situation is 0.165.

In the same way, we can get the weight of the second level index based on the first level index:

Table 3　Weight of the Evaluation Index

First level index	Weight	Second level index	Weight
Local economic development	0.622	Real GDP per capita	0.87
		GDP growth	0.13
Local financial situation	0.213	Ratio of financial revenue and expenditure	0.657
		Elastic coefficient of government receipts	0.343
Local government debt situation	0.165	Debt-to-GDP	0.21
		Debt per capita	0.66
		Debt-to- government receipts	0.13

3.2 Model synthesis

3.2.1 Model synthesis for first level index

$$A_i = \sum(\omega ij Rij) \tag{4}$$

A_i represents the evaluation result of the i-th first level index, and ω_{ij} represents the weight of the j-th second-level index based on the i-th first-level index, and R_{ij} represents the evaluation result of the j-th second-level index based on the i-th first level index.

3.2.1 Model synthesis for evaluation index system

$$L = \sum(Ai \ \omega i) \tag{5}$$

L represents the evaluation result of local government debt risk, A_i represents the evaluation result of the i-th first-level index, and the ω_i represents the weight of the i-th first-level index.

4 An Empirical Study on the Local Government Debt Risk in China

On the basis of the evaluation index system, 15 provinces in China were selected to access and the initial dates are from *2016 National Fiscal Settlement*.

Since the criteria of each index are different, the evaluation results of the index should be non-dimensionalized. In order to make the data intuitive and easy to read, and to reflect the difference of positive and negative index, the evaluation result of the non-dimensionalized positive index is multiplied by 100, and the negative index is multiplied by -100. The final evaluation results are as shown in the table 4. The result has been ordered from highest risk to lowest and the local government debt risk presents a regional difference, so the paper classifies them into economic divisions to make an empirical study.

Table 4　Evaluation Results of Local Government Debt Risk of 31 Provinces and Cities in China

Provinces or cities	Local economic development	Local financial situation	Local government debt situation	Local government debt risk
Qinghai	-2.45528	2.532237	6.382784	0.065344
Yunnan	-1.90053	-1.65747	4.144268	-0.85136
Heilongjiang	-2.12397	-0.74421	2.486178	-1.0694
Guangxi	-2.29783	-2.35615	2.867291	-1.45801
Sichuan	-2.41543	-2.15988	2.718082	-1.51397

Continual Table 4

Provinces or cities	Local economic development	Local financial situation	Local government debt situation	Local government debt risk
Jiangxi	-2.49158	-1.85085	2.421323	-1.54448
Shanxi	-1.868	-3.7537	1.820106	-1.66111
Jilin	-2.92619	-2.39137	2.795407	-1.86821
Anhui	-2.46078	-4.8036	2.455596	-2.1486
Hubei	-3.24694	-3.08899	2.232846	-2.30913
Liaoning	-4.57914	-3.14657	4.898226	-2.71024
Zhejiang	-4.67694	-6.41738	3.36632	-3.72052
Guangdong	-4.16731	-6.68222	1.778748	-3.72189
Beijing	-5.24151	-5.76139	2.911071	-4.00707
Shanghai	-6.35793	-8.89922	3.753102	-5.23091

The four economic divisions are Eastern China (Beijing, Shanghai, Zhejiang, Guangdong,), Central China (Shanxi, Anhui, Jiangxi, Hubei), Western China (Guangxi, Sichuan, Yunnan, Qinghai), Northeastern China (Liaoning, Jilin, Heilongjiang).The paper takes the average of the evaluation result of provinces to assess the local government debt risk of the economic divisions and calculates their variances. The result is as shown in the table 5.

Table 5   Evaluation Result of Economic Divisions and The Variance

Economic division	Local economic development	Rank	Local financial situation	Rank	Local government debt situation	Rank	Local government debt risk	Rank	Variance	Rank
Eastern China	-4.49	1	-5.12	1	3.06	3	-3.38	4	1.02	4
Central China	-2.55	3	-3.46	2	2.24	4	-1.96	3	0.07	1
Northeastern China	-3.21	2	-2.09	3	3.39	2	-1.88	2	0.45	2
Western China	-2.51	4	-1.81	4	3.81	1	-1.32	1	0.46	3

4.1 Impact of local economic development on local government debt risk

Local economic development is the most vital to the debt risk. We learned that the weight of economic development is the mostwhen calculating it. Additionally, regional rank of local economic development is almost the same as the regional rank of debt risk. So, the impact of economic development is higher.

4.2 Impact of local financial situation on local government debt risk

The weight of local financial situation is far below the economic development and the effect is smaller. It also presents in the comparisons of economic divisions. If a province is well-developed in economy but ignores finance, the debt risk will get higher than others with lower economic development.

4.3 Impact of local government debt situation on local government debt risk

Local government debt has the smallest impact on the local government debt risk. And the debt balance is not related to the debt scale. The weight of local government debt situation is the least, so it has minimal impact on local government debt risk. But it cannot be ignored when it is extreme. Besides, all second-level indexes of local government debt situation adapt debt balance as statistic. But debt balance has nothing to do with the local government debt situation. The debt risk scale refers to the matching degree between the debt and finance or economy. So, borrowing more debt can't be worse.

5 Conclusion

Based on AHP, the paper builds the evaluation system, accesses the risk of 15 provinces in 2016 in China, makes an empirical analysis and draws conclusions and gives suggestions as follows.

5.1 Eastern China

Eastern China has a greatest economy and the lowest debt risk, but the variance is large, indicating that the risk varies greatly in the division, and the development in the region is not balanced.

The eastern region, relying on its great debt-payment base, can continue to expand its debt scale.

But it should care the imbalanced debt risk. It is suggested that the well-developed provinces should help the backward provinces to reduce the debt risk by improving the local economic development.

5.2 Western China

The local government in the west has the least debt (the least debt balance), but the development is backward dueto the inactive economic activityand it can't offer a hunk repayment base for the debt, leading to the relatively-large debt balance. So, local government debt situation and debt risk isterrible.

It is suggested that the western region should focus on economy, attract external population and increase business activities. Besides, if expanding the debt scale to obtain funds is good for economic development, it can increase local government debt with orderly debt management.

5.3 Central China

Local government debt risk and the variance of Central China is both not large. Besides, the local government debt situation is in good condition. Those show that the debt management is reasonable, and debt risk is mainly caused by low level of economic development.

It is recommended that the Central China keep the good debt management and focus on economy. Without improvement in economy, it shouldn't increase the debt balance, otherwise the economic and financial resources will not support the expanded debt scale, leading to increasing the debt risk.

5.4 Northeast China

The debt risk in Northeast China is between Eastern and Central, and the economy is second only to Eastern. But debt situation and financial situation are behind so the finance and debt management need improving. Besides, the variance is big, showing the debt risk and economy are imbalanced.

The local government in Northeast China should focus on debt and financial management, take administrative norms seriously and compile the budget of government debt strictly. Besides, provinces need to help each other, strengthen economic connections, develop together and avoid the debt risk.

Abstract：In flight accident statistics, we find that flight accidents or incidents have been increasing year by year because of aircrew errors. To further improve the current level of aviation safety, the issue of how to overcome and avoid the occurrence of human error of aircrews has become important for all countries in the world. Based on the grounded theory, influencing factors of psychological health risks have been identified. AHP was used to construct the evaluation index system and fuzzy comprehensive evaluation model. Through empirical analysis, the model's scientific and applicability were verified. The results laid the foundation for further research on mental health risk of civil aviation crew, and provided a basis for civil aviation organization to control crew's mental health risk. At the same time, it also helps to improve the quality of work and life of aircrews.
Key words: Civil aviation crew; Mental health risk; Evaluation index; Fuzzy comprehensive evaluation

1 Introduction

According to the flight data statistics, the main cause of the aviation accident has changed from the initial aircraft itself to the factor of adult, and the analysis of the flight accidents in recent years found that the main cause of the accident is closely related to the mental health problems of the crew. For example, the incident in 2015, the main cause of the accident was the suicidal tendencies of the deputy captain, Rupez, who was found to have serious depression and had a strong dependence on the drug. Due to the nature of the work, civil aviation crew faces greater psychological pressure, safety responsibility and mental health risk, which is likely to cause flight safety risk. How to identify and control the psychological health of the crew is attracting more attention from scholars and airlines. Therefore, the construction of the mental health risk assessment model of the civil aviation crew can effectively prevent the risk of mental health of the crew and have certain guiding significance for the effective treatment of mental health problems, thus improving the level of flight safety.

The existing literature shows that many scholars at home and abroad have studied the crew's mental health risk. In the early study of foreign scholars, the factors that could cause mental health risk of pilots were explored: Lazarus (Lazarus, 1976) believed that flight would cause fear of spontaneous combustion, and that pilots were prone to psychological problems if they were not able to respond properly.Strongin (Strongin, 1987) research the phobia of pilots on the basis of the former study and find that it was mainly due to a mental disorder caused by the pilots' failure to adapt well to the environment; the factors affecting the mental health of the pilots were found byRobert Bor (Robert Bor, 2010)， including personality, lifestyle, psychological quality, adaptability, irritable response, and drug dependence. Compared to foreign scholars, domestic scholars started late, and the research in recent years, the results are more prominent, mainly from the personal factors, family factors, organizational factors, social factors and other factors that affect the psychological health of pilots: (Wang Ling , 1998)through the analysis of 115 flight attendants find that there were existed obvious psychological symptoms, and the factors affecting their mental health were: Flying age, working pressure, negative coping style, personality characteristics, physical condition, etc. Ma Wenjie (Ma Wenjie, 2002) analyzed 123 air crew using SCL-90 and 16PF scale to study the general personality characteristics and mental health of the power flight. It was found that age and working age had an impact on the mental health of flight attendants; SuHeng (SuHeng, 2006) found a positive relationship between the mental health of pilots and marriage, and the improvement of the quality of marriage was helpful to improve the mental health of pilots; Lou Zhenshan (Lou Zhenshan, 2009) adopted a self-rating scale to analyzed 428 air crew, the survey was conducted to study the role of life events, self-consistency and congruence and mental health. The research of scholars at home and abroad has great inspiration for this subject, but it can be found that the scholars are mainly studying several specific factors in the dimensions of individual, organization, society and family, but the mental health problem of the crew is a complex problem, and it is the result of the joint action of multidimensional strength. In order to make a comprehensive and in-depth study on the factors that affect the mental health of the crew from the perspective of the whole, it have a great significance to design a set of risk assessment model for the mental health of the crew. This study uses analytic hierarchy process (AHP) combined with fuzzy

comprehensive evaluation, and uses scientific standards and objective data to improve the ability of aviation organization to cope with the mental health risk of aircrew.

2 Factors Affecting Mental Health Risk of Civil Aviation Crew

In recent years, the civil aviation crew has received extensive attention from the society. Many media have carried out extensive reports on it, leaving a rich and traceable information on the Internet. Based on the root theory, the research using open coding, spindle coding, selective coding and saturation test to analyzed the original data on the network. The source of the data is mainly the information network, the civil aviation network, the Chinese civil aviation network and other media. Through the search of "pilot mental health", "air crew mental health", "pilot + risk", "flight attendants + risk" and other key words, a total of 108 data matching this research, total 125842 words.

2.1 Open coding

In order to ensure the objectivity and accuracy of the coding, we should try to summarize the original sentences in the process of labeling and conceptualization. After preliminary integration, 182 related concepts are obtained. After comparative analysis, there are more related words in the concept. In order to make the theory clearer, through the comparison and analysis of the 182 concepts, 53 categories of psychological control tendency, trait anxiety and disguise psychology are obtained according to their relevance.

2.2 Spindle coding

Spindle coding mainly focuses on discovering the relationship between categories, and establishing data association. According to the logic of "phenomenon and its cause, background, intermediary conditions, action and interaction strategies and results", the depth analysis of 53 categories has been carried out and found that there have certain causation, semantic relations, situation relations and process relations among these categories. We categorize these categories according to their relevance and get 19 main categories: work events, industry events, social events and so on.

2.3 Selective coding

Selective coding is to find a core category between categories, and integrate the whole category in a story line way, and form a theory based on this. The core category must be representative, appears repeatedly in the text, and can play an important role to the whole paper. It is found that the occurrence process of mental health risk of civil aviation crew is more consistent with the paradigm of "stress quality interaction model". On this basis, 5 core categories are found, namely stress and emotional events, psychological quality, recognition evaluation, coping style and support system.

Through the saturation test, it is found that, due to the sufficiency and comprehensiveness of the data, there are several new concepts in the saturation test process, but there is no new category and new structural relationship, so the theory is saturated. Finally, we get the mental health risk factors of civil aviation crew as shown in Table 1.

Table 1   Factors Influencing the Mental Health Risk of Civil Aviation Crew

the first level	the second level	the third level
Stress and emotional events	Work events	the nature of work, working environment, job burnout, job characteristics, work behavior, job stress, work intensity, job requirements, job expectations,job satisfaction, working atmosphere
	Industry events	Industry events, trauma events, market environment atmosphere
	Social events	Social events
	Organizational events	Organization management, management mode, organizational justice, management system, punishment system, organization concern and salary system
	Life events	Lifestyle, diet, sleep disorders, family events, life events, physical health and emotional health
Cognitive evaluation	Personality traits	Personality traits
	Personal cognition	Personal cognition
	Emotionalperception	Emotional perception
Coping style	Coping tendency	Coping tendency, social avoidance, social distress and trait coping
	Coping behavior	Coping behavior

Continual Table 1

the first level	the second level	the third level
Psychological quality	Personalbasic situation	Personal skills, age, working experience, education level and position.
	Psychological control tendency	Psychological control tendency, trait anxiety, disguised psychology and risk tolerance.
	Psychological feature	Psychological feature
	Psychological needs	Psychological needs
	Mental disorder	Mental disorder
Support system	Personal support	Interpersonal relationship, self-harmony, self-regulation
	Organizational support	Organizational support, sense of belonging and psychological intervention
	Social support	Passenger feedback, passenger quality, passenger support, cultural support and social cognition
	Family support	Family support, family responsibilities, family emotions, family events and family characteristics

3 Fuzzy Comprehensive Evaluation Method

3.1 Civil aviation crew mental health risk assessment index system

The psychological health risk factors of the civil aviation crew identified by this study are clear, and the evolutionary process of the mental health risk of the civil aviation crew is clearly demonstrated, and the psychological health risk of the civil aviation crew can be effectively judged according to the various influencing factors. Based on the analytic hierarchy process, the index of Table 1 is weighted. At the same time, combined with the expert scoring method, the factors of the mental health risk of civil aviation crew were reported to 10 experts in the field of aviation and risk management. On the basis of consulting the factors affecting the mental health risk of the civil aviation crew, the opinions of the civil aviation crew members' psychological health risk assessment index system are constructed, and then the influence factors are presented according to the expert opinion. The evaluation index is presented in the form of "working environment status", and the "salary system" is presented as "satisfaction of salary system", and "passenger feedback" is presented as "negative feedback rate of passengers". Finally, the evaluation index system of mental health risk of civil aviation crew is constructed, which are divided into three index levels. The first level index number is 5, the two level index number is 19, and the three level index number is 53. Therefore, we get the mental health risk evaluation index system of civil aviation crew shown in Table 2.

Table 2　MentalHealth Risk Assessment Index System for Civil Aviation Crew

Target index	First grade index A	Secondary index C	Tri-grade index D
All Health Risk of Civil Aviation Crew	Stress and emotional events A_1	Work events C_1	Job environment D1, job burnout D2, occupational disease D3, work stress intensity $_{D4}$, job satisfaction D5
		Industry events C_2	The incidence rate of negative industry events $_{D_6}$ trauma events encounter D7, pilots are short of $_{D_8}$, job hopping atmosphere $_{D_9}$
		Social events C_3	Incidence of negative social events $_{D_{10}}$
		Organizational events C_4	Communication barrier $_{D_{11}}$, Sense of organizational justice $_{D_{12}}$, The rationality of the punishment system $_{D_{13}}$, Degree oforganizational care $_{D_{14}}$, Satisfaction of salary system $_{D_{15}}$
		Life events C_5	Law of life $_{D_{16}}$, Sleep disorder $_{D_{17}}$, Incidence of negative family events $_{D_{18}}$, Incidence of negative life events $_{D_{19}}$, Health $_{D_{20}}$
	Cognitive evaluation A_2	Personality traits C_6	Anxiety personality matching degree $_{D_{21}}$
		Personal cognition C_7	Personal cognitive bias $_{D_{22}}$
		Emotional perception C_8	Emotional sensitivity $^{D_{23}}$ Negative tendencies $^{D_{24}}$,

Continual Table 2

Target index	First grade index A	Secondary index C	Tri-grade index D
All Health Risk of Civil Aviation Crew	Coping style A_3	Coping tendency C_9	Social avoidance D_{25}, social distress D_{26}
		Coping behavior C_{10}	Negative coping intensity D_{27}
		Personal basic situation C_{11}	age D_{28}, Working life D_{29}, Degree of Education D_{30}, post D_{31}
	Psychological quality A_4 Continual Table 2	Psychologicalcontrol tendency C_{12}	Negative psychological control tendency D_{31}, Trait anxiety intensity D_{33}, Camouflage psychological intensity D_{34}, Risk toughness D_{35}
		Psychological feature C_{13}	High trait anxiety intensity D_{36}
		Psychological needs C_{14}	Satisfaction degree of psychological demand D_{37}
		Mental disorder C_{15}	Intensity of mental disorder D_{38}
		Personal support C_{16}	Relationship D_{39}, Self-harmony intensity D_{40}
		Organization support C_{17}	Organizational support D_{42}, Sense of belonging D_{43}, Rationality of psychological intervention D_{44}, Passenger negative feedback rate D_{45}, The degree of difficulty of passengers D_{46},
		Social support C_{18}	Cultural binding force D_{47}, Symmetry of information D_{48}
		Family support C_{19}	Family contradiction D_{49}, Stress intensity of family responsibility D_{50}, Family emotional debt intensity D_{51}, Marital satisfaction D_{52}

It can be seen from table 2 that there are more qualitative indicators for the evaluation index system of mental health risk of civil aviation crew, which have obvious fuzzy nature, and the general risk assessment method is difficult to be measured accurately. The fuzzy comprehensive evaluation method can effectively deal with the evaluation problem with the fuzzy property, and can effectively deal with the subjective problems in the evaluation process. Therefore, the fuzzy comprehensive evaluation method is adopted to evaluate the mental health risk of the civil aviation crew.

3.2 Determine the set of evaluation factors

There are 3 levels of mental health risk assessment index system for civil aviation crew, so set up the evaluation factors set: $U = [U_i \quad U_{ii} \quad U_{iii}]$, U_i=[three level indicators,53 factors], U_{ii}=[two level indicators, 19 factors], U_{iii}= [level one index, 5 factors, namely: stress and emotional events, cognitive evaluation, coping style, psychological quality, support system].According to the "high risk", "moderate risk", "mild risk" and "safety", the assessment level of the mental health risk of civil aviation crew is divided into 4 categories, so set the evaluation V={high risk, moderate risk, mild risk, safety}. Qualitative evaluation is used to determine the set of reviews.

3.3 Determine the evaluation set and evaluation criteria

According to the "high risk", "moderate risk", "mild risk" and "safety", the assessment level of the mental health risk of civil aviation crew is divided into 4 categories, so the evaluation set V= {high risk, moderate risk, mild risk, safety}. The method of qualitative evaluation is used to determine the set of comments.

3.4 Determination of weight set and evaluation matrix

According to the index system, we set up the weight set W. A weight vector W_i representing the importance of the factor in the two level index. An expert scoring method is used to determine the set of comments R for each index. 10 experts were asked to evaluate their risk indicators according to their evaluation criteria. After the index is compared in the column that matches the crew's situation, the

number of votes for each evaluation object is summed up by M_{ij}, and the M_{ij} is divided by 10, and M_{ij} is the evaluation membership value of the evaluation object. And i=1, 2, 3... 19, j=1, 2, 3, 4.

Statistics of expert scoring results are made to determine the membership degree of each evaluation factor, and the fuzzy relation matrix of each indicator is constructed with two levels of indicators. That is the fuzzy relation matrix of the I index of the two level index, i=1, 2, 3,... 19.

3.5 Multilevel comprehensive evaluation

Using $B = A \cdot R$ to calculate the membership degree of each index, the mental health risk assessment results of civil aviation crew are determined according to the maximum membership degree principle. Because the mental health risk index system of civil aviation crew contains three levels of indicators, multilevel fuzzy comprehensive evaluation is needed.

(1) First level comprehensive evaluation

The membership degree of the two level evaluation index is expressed by the weight vector of the factors. It represents the lower level index contained in the I index of the two level index relative to its comprehensive operation result. It represents the I index contained in the two level index relative to its weight vector.

$$C_i = W_i \cdot R_i \tag{1}$$

(2) Two level comprehensive evaluation

The result of the comprehensive evaluation of the I element in the expression and index is calculated.

$$A = W_a [C_1 \quad C_2 \quad \cdots\cdots \quad C_k]^T \tag{2}$$

W_a represents the weight vector of the subordinate indicators of a level index relative to its importance.

(3) Three level comprehensive evaluation

The result of fuzzy comprehensive evaluation of target layer is constructed

$$P = W [A_1 \quad A_2 \quad A_3 \quad A_4 \quad A_5]^T \tag{3}$$

According to the principle of maximum membership, the risk state corresponding to the maximum value is the mental health state of the crew.

4 Case Analysis of Mental Health Risk Assessment forCivil Aviation Crew

4.1 Introduction of the basic situation of risk assessment object

SF is a private air freight company, which is a joint venture by a number of companies. It serves the air express transportation industry of a domestic express company, and has a lot of experienced crew. Taking 3 crew members of a unit of SF aviation limited as an example, the mental health risk status of the crew was evaluated. The basic situation of 3 crew members was shown in Table 3, as shown in Table 3.

Table 3   Evaluation of the Basic Situation of the Object

Evaluation Object Number	Post	Age	Working Life	Degreeof Education
1	captain	38	15	graduate
2	copilot	29	3	Junior college
3	trainee	26	2	Undergraduate

4.2 SF airline crew psychological health risk assessment

10 experts in the field of aviation and risk management are invited to evaluate the risk index evaluation criteria for 3 crew members of SF airlines and determine their degree of membership according to the votes of each index. Because of the limit of space, one of them was selected randomly, and the score of his mental health risk assessment index was illustrated in detail, and the final object of the evaluation was taken as an example. For example, 10 experts evaluated "2" "work environment status" indicators, a total of 0 experts selected "high risk", so the score was 0; 3 experts chose "moderate risk", so the score was 0.3; 6 experts chose "mild risk", so the score was 0.6; there were 1 experts choosing "safety". The score was 0.1. The evaluation matrix of "object 2" and "working environment condition" is obtained, and the membership degree of other indicators can be obtained similarly.

4.2.1 Determination evaluation matrix

Based on table 1, a fuzzy relation matrix R is constructed. For example, the fuzzy relation matrix R_1 representing work events contains factors, D_1、D_2、D_3、D_4、D_5, and, according to table 2:

$$R_1 = \begin{bmatrix} 0 & 0.3 & 0.6 & 0.1 \\ 0 & 0.3 & 0.5 & 0.2 \\ 0 & 0.1 & 0.6 & 0.3 \\ 0.1 & 0.7 & 0.2 & 0 \\ 0 & 0.3 & 0.6 & 0.1 \end{bmatrix}$$

Similarly, the fuzzy relational matrix of two indicators and other indicators is constructed. R_2, R_3, R_4,……R_{19}.

4.3 Multilevel comprehensive evaluation

The psychological health risk of crew members of SF airline is evaluated.

According to formula (1-3), we made three level comprehensive evaluation of the psychological health risk of SF company crew.

The final comprehensive evaluation results are as follows:

$$P = W \begin{bmatrix} A_1 & A_2 & A_3 & A_4 & A_5 \end{bmatrix}^T = \begin{bmatrix} 0.02970 & 0.20622 & 0.55583 & 0.21450 \end{bmatrix}$$

That is to say, the psychological health risk assessment results of a SF aircrew "2" are:

Table 5   PsychologicalHealth Risk Assessment Results of SF Airline Crew

Results of mental health risk assessment for civil aviation crew	Evaluation Criterion			
	High risk	Middle risk	Mild risk	Safety
	0.02970	0.20622	0.55583	0.21450

According to the principle of maximum membership, the psychological health risk of crew members is 0.55583, so the risk level is "mild risk".

Similarly, the risk assessment results of the other 2 crew members of a SF airline are obtained respectively, as shown in Table 6:

Table 6   PsychologicalHealth Risk Assessment Results of SF Airline Crew

Evaluation object number	Evaluation Criterion			
	High risk	Middle risk	Mild risk	Safety
①	0.00872	0.31255	0.32229	0.35644
③	0.01288	0.16448	0.35684	0.46580

According to the principle of maximum subordinate degree, the mental health level of the evaluation subjects is "safety" and "safety". SF airlines need to take risk management measures to prevent risks from deteriorating.

5 Conclusion

According to the weight of the mental health risk assessment index of the civil aviation crew and the psychological health risk assessment results of the 3 aircrew of SF airlines, it is found that the most important factors affecting the mental health risk of the crew are mainly focused on the psychological quality, personal support, organizational support, personality traits, coping behavior ， work and family support. Therefore, the center of control of the mental health risk of the civil aviation crew should be placed on the promotion of personal psychological quality, the ability to adapt to the individual's ability to adapt to work and the ability of self-support, to take active intervention measures from the point of organization, to make a reasonable work plan and to reduce the pressure of work.

The main innovation of this study is to analyze the data related to the mental health risk of the crew by using the grounded theory. Based on the stress quality interaction model, the factors affecting the mental health risk of the civil aviation crew are identified. In addition, on the basis of the factors affecting the mental health risk of the civil aviation crew, based on the comprehensive risk management theory, the evaluation index system of the mental health risk of the civil aviation crew is constructed.

This paper uses analytic hierarchy process (AHP) and fuzzy comprehensive evaluation method to evaluate the mental health risk of the civil aviation crew, and makes a comprehensive analysis on the factors that affect the mental health of the crew, and has a comprehensive and thorough research on the factors that affect the mental health of the crew from the overall point of view. At the same time, we explore a more suitable method to study the factors influencing the mental health of crew, and have

more practical significance. Overcoming the drawbacks of subjective assumptions. However, the weight of the mental health risk assessment index of civil aviation crew has not been verified in the study, which can be further studied later.

Financial Market Environment, Enterprise Lifecycle and Inefficiency Investment

Zhu Kai, Shen Jun
School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: kay9407@foxmail.com, sjarr@whut.edu.cn)

Abstract: Taking the data of small and medium-sized listed companies in China from 2010 to 2014 as the sample, this paper uses the Richardson's model to test how financial market environment affects inefficiency investment of enterprises in different lifecycle phases. The result indicates that: for the whole sample, completing financial market environment has no significant impact on overinvestment and underinvestment; for samples in different lifecycle phases, completing financial market environment will inhibit overinvestment in the introduction, exacerbate overinvestment in growth, exacerbate the underinvestment of growth and decline; with the completing of financial market environment, inefficiency investment will be more serious.
Key words: Financial market environment; Enterprise lifecycle; Inefficiency investment; Overinvestment; Underinvestment

1 Introduction

China has implemented the policy of supply-side structural reform since 2015. This policy focuses on accelerating the reform of the financial system and lifting financial repression, improves the external environment of the enterprise effectively, facilitates the optimal allocation of factors, suppresses inefficient investments, and improves the overall economic level of China. Financial market environment, as an important part of enterprises' external environment, has been confirmed to have a significant impact on investment activities. The financial market environment in China are different among regions (Cai Wenhao et al., 2017). Besides, the survival and development statement of financing subjects vary with financial market environment (Liu Yanhong, 2014). Therefore, the research about how financial market environment influence inefficiency investment is of theoretical and practical significance.

Investment efficiency means that the ratio of the enterprise's achievements to the occupied and consumed resources in investment. It is one of the most important criteria for measuring the rationalization of resource allocation in the enterprise. When the enterprise's the input of resources does not match the output of outcomes, it means inefficient investment—specifically, it could be overinvestment or underinvestment (Garcá Lara, J.M. et al., 2016). As far as the listed companies in our country is concerned, overinvestment and underinvestment are widespread (Huang Xianhuan and Wu Qiusheng, 2017). Enterprises in different lifecycle phases will be different when they are making decisions on management, investment, and financing (Wang Bingcheng, 2011). Besides, investment activities will always coincide with the phase of the enterprise's lifecycle (Yuan Rong, 2016). Xie Peihong and Wang Chunxia (Xie Peihong and Wang Chunxia, 2017) indicated that enterprises' condition of inefficient investment will also vary with the lifecycle phases. Therefore, when researching on inefficient investment, enterprise life cycle must be concerned.

Researches show that the financial market environment could have a significant impact on investment activities in many aspect, and enterprises in different lifecycle phases will be different when it comes to inefficient investment. However, there still lack research about how financial market environment influence inefficient investment, and there is even rare research had lifecycle phases into account. In terms of theoretical significance, the research on how could financial environment influence inefficiency investment from the perspective of the lifecycle could makes up the research gaps about financial environment and inefficient investment, and at the same time enrich the enterprise lifecycle theory. In terms of realistic significance, how could financial environment influence inefficient investment, and what are the differences of its influence in different lifecycle phases? The answers to these questions are of vital importance to policy making, investment decisions, and enterprise management.

2 Literature Review, and Hypotheses

Financial market environment includes the credit institutions, the investment institutions, the

intermediary agencies, the domestic securities market and foreign securities markets.Completing the financial market environment can affect inefficient investment by expanding market capacity and alleviating information asymmetry (Irani M and Oesch D, 2015). As far as expanding market capacity is concerned, for example, the exploration of new modes of investment and financing expands the capacity of financial market. Wang Xiao and Lai Yanyun (Wang Xiao and Lai Yanyun, 2014) got the conclusion that when small and medium-sized enterprises can obtain sufficient funds from the outside, their internal financing motivation will be more weakened. So, multi-dimensional funding could help enterprises to disperse risks. Sheng Shijie (2016) found that with the development of guarantee agencies, the financing difficulties of small and medium-sized enterprises can be effectively alleviated. Wang Yixin (Wang Yixin, 2017) stated that in the background of online finance, the cooperation between online finance and commercial banks could ease the financing difficulties of small and medium-sized enterprises. Besides, according to the effective market theory, we could know that the completing of financial market environment could relieve the information asymmetry between enterprises and investors (Zhang Tiezhu and King Howe, 2017). Xiao Min (Xiao Min, 2014) pointed out that information asymmetry will lead to investors' adverse selection behavior, which makes the enterprise cash flow redundant or insufficient and causes inefficiency investment. Wang Chaoen (Wang Chaoen, 2016) found that there are significant regional differences in investment and financing activities in China, and the completing of financial market is an important factor in the investment and financing activities of enterprises. Based on this, the following assumptions are put forward:

H1: Completing financial market environment can correct inefficient investment.

H1a: Completing financial market environment can inhibit overinvestment.

H2b: Completing financial market environment can alleviate underinvestment.

Scholars began the study on lifecycle from the theory of Haire (Haire, 1959). They studied the enterprise from the perspective of bionics, and came to the conclusion that the process of enterprise development is similar to biological growth. The later researches enriched the concept of the enterprise lifecycle, gradually began to explore the way of dividing the enterprises lifecycle phase, then formed some mainstream theories, like 'three phases', 'four phases' and 'five phases'. Although there is no consensus among scholars about the division of enterprise lifecycle, the methods of division are mainly based on the way how enterprises operate, invest and finance. And it is generally believed that enterprises in different lifecycle phases have differential characteristics (Chen Chen, Li Zhe, Wang Lei, 2016). Domestic scholars usually use the theory of Anthony and Ramesh (Anthony and Ramesh, 1992) or Dickinson (Dickinson, 2011) when they are considering the division of enterprise lifecycle. In order to avoid endogenous problems, we use Dickinson's theory to define the lifecycle phases, divide the whole lifecycle into four phases, as shown in Table 1.

Table 1   the Division of Enterprise Lifecycle

	The sign of cash flow	The sign of investment cash flow	The sign of financing cash flow
Introduction	-	-	+
Growth	+	-	+
Maturity	+	-	-
Decline		others	

Zhu Konglai (Zhu Konglai, 2012) pointed out that the phases of institutional investors' action are often accordant with the phases of enterprise lifecycle. So, the inefficient investment states of enterprises also vary with enterprise lifecycle phases. The causes for this phenomenon are from a number of aspects, current studies tend to focus on the internal factors of the enterprise. For example, Luo Qi and Li Hui (Luo Qi and Li Hui, 2015) proposed that distinct dividend policies may cause diverse inefficient investment states in different enterprise lifecycle phases. Chen Yuan (Chen Yuan, 2015) did a research from the perspective of behavioral economics, and found it that the self-interest of management may also lead to periodic differences on inefficient investment in different lifecycle phases. Financial market environment is one of the most important factors when it comes to external environment of enterprise. However, it is not clear how it influences inefficiency investment in different phases of lifecycle. So, we made the following assumptions.

H2: With the change of lifecycle, financial market environment has different correcting effect on inefficient investment.

H2a: With the change of lifecycle, financial market environment has different inhibiting effect on overinvestment.

H3b: With the change of lifecycle, financial market environment has different exacerbating effect on underinvestment.

3 Experimental Method
3.1 Variable definition
3.1.1 Inefficient investment

This paper quantifies inefficient investment in the basis of Richardson's theory. In this theory, the total investment expenditure of the enterprise is the sum of the investment expenditure of the current project and the investment expenditure of the new projects. And the investment expenditure of the new projects is divided into two parts: the reasonable investment expenditure and the inefficiency investment. Besides, considering that the samples are small and medium size listed companies, their listing conditions are special compared with companies in main board. In order to ensure the robustness of the results of this study, we remove one variable which means companies' listed years. The new model for inefficiency investment is following:

$$Inew_t = \beta_0 + \beta_1 Inew_{t-1} + \beta_2 Growth_{t-1} + \beta_3 Lve_{t-1} + \beta_4 Cash_{t-1} \\ + \beta_5 Size_{t-1} + \beta_6 Ret_{t-1} + \Sigma Year + \Sigma Ind + \varepsilon \tag{1}$$

In this model, investment expenditure（$Inew_t$）is the interpreted variable, and its forecast value is determined by the company's growth, its size and so on. The residual(ε) of this model means inefficient investment. If the residual is positive, it means overinvestment. If the residual is negative, it means underinvestment. In addition, the higher the absolute value of the residual, the more inefficient investment the enterprise is. And the lower the absolute value of residual, the less inefficient investment the enterprise is. Inv_t minus Im_t is $Inew_t$, and it means new investment in the given year. Inv_t is equal to the sum of 'cash payments for the construction of fixed assets, intangible assets and other long-term assets', 'cash paid for purchase and disposal of subsidiaries and other business units', 'cash paid by equity investment' and 'cash paid by bond investment' minus 'net cash recovered from disposal of fixed assets, intangible assets and other long-term assets' in cash flow statement, then divided by total assets at the beginning of the year. Im_t is the ratio of depreciation plus amortization of long-term assets to total assets at the beginning of the year?

3.1.2 Financial market environment

Scholars have different definitions in financial market environment. Zhou Bing (Zhou Bing, 2014) used financial depth to represent financial market environment. Wang Lei (Wang Lei, 2015) defined the financial market environment from three dimensions: financial scale, financial structure and financial efficiency. Wei Chengcheng (Wei Chengcheng, 2017) also defined the financial market environment from three dimensions. It is obvious that the definition dimension of financial market environment is changing from single to pluralistic. Considering the realistic significance of this research, we use China's Provinces Marketization Index Report's way (2016) to define financial market environment. The index defines the financial market environment from five dimensions: the relationship between the government and the market, the development of the non-state economy, the development of the product market, the score of the development degree of the factor market, the development of the market intermediaries and the scoring of the legal system environment. The higher the index, the more perfect the financial market environment.

3.2 Empirical model

According to the hypotheses, the model is following:

$$OverInv_{i,t} = \beta_0 + \beta_1 Financial_t + \beta_2 Growth_{t-1} + \beta_3 Lev_{t-1} \\ + \beta_4 Cash_{t-1} + \beta_5 Size_{t-1} + \beta_6 Ret_{t-1} + \Sigma Year \\ + \Sigma Ind + \varepsilon \tag{2}$$

$$UnderInv_{i,t} = \beta_0 + \beta_1 Financial_t + \beta_2 Growth_{t-1} + \beta_3 Lev_{t-1} \\ + \beta_4 Cash_{t-1} + \beta_5 Size_{t-1} + \beta_6 Ret_{t-1} + \Sigma Year \\ + \Sigma Ind + \varepsilon \tag{3}$$

The definition of the variables in models is shown in Table 2. The formula (2) is used to test hypotheses H1a, H2a, H3a and H4a, and the formula (3) is used to test hypotheses H1b, H2b, H3b and H4b.

Table 2   the Definition of Variables

The types of the variates	Variables	Symbol	Definition
Interpreted variable	Overinvestment	OverInv	The residuals of samples whose residuals are positive in model (1).
	Underinvestment	UnderInv	The residuals' absolute value of samples whose residual are negative in model (1).
Explanatory variable	Financial market environment	Financial	The appropriate index in China's Provinces Marketization Index Report's way (2016).
	Enterprise growth	Growth	Growth rate of main business income.
	Enterprise debt ratios	Lev	Balance sheet.
Control variable	Cash holdings	Cash	The amount of cash at the end of the year /total assets.
	Enterprise scale	Size	Natural logarithm of total assets.
	Stock returns	Ret	Stock return.

3.3 Data source and sample selection

We use the financial data of small and medium enterprise board listed company from 2010 to 2014 as the initial sample, totally including 3349 samples. To ensure the effectiveness of the research, we filtered data in the following ways:(1) rejecting 45 samples which are financial companies;(2) rejecting 35 samples which are marked as ST, *ST and PT companies;(3) rejecting 695 samples which are lack of financial data. And we got 2594 final samples which are shown in table 3.

Table 3   Sample Distribution in Different Lifecycle Phases

Lifecycle phases	Overinvestment		Underinvestment		Total	
	number	ratio	number	ratio	number	ratio
Introduction	173	6.67%	243	9.37%	416	16.04%
Growth	379	14.61%	414	15.96%	793	30.57%
Maturity	321	12.37%	656	25.29%	977	37.66%
Decline	117	4.51%	291	11.22%	408	15.73%
Total sample	990	38.16%	1604	61.84%	2594	100.00%

It can be seen from the table, small and medium size board listed companies at all phases of the lifecycle and the whole sample, underinvestment is more common than overinvestment.

4 Analysis of Empirical Results

4.1 Descriptive statistics

Descriptive statistics of variables in the empirical model are shown in Table 4. The average, standard deviation and extreme difference of the overinvestment group are greater than those of the underinvestment group, and it indicates that the overinvestment situation is more serious than the underinvestment in the sample. The average of the financial market environment group is less than its median, and the standard deviation and the gradation are both large. On the one hand, the financial market environment in China has developed rapidly in recent years. On the other hand, the financial environment in China has a relatively obvious regional imbalance, and most of the small and medium-sized enterprises are in the areas where the financial environment is not superior. Other control variables, which are not the focus of this paper, will not go into details.

Table 4   Descriptive Statistics

Variable	Quantity	Average	Standard deviation	Median	Maximum	Minimum	Extreme difference
OverInv	990	0.17	0.50	0.07	0.00	13.92	13.92
UnderInv	1604	0.08	0.11	0.06	0.00	2.94	2.94
Financial	2594	8.06	1.42	8.31	9.95	-0.30	10.25
Growth	2594	0.36	7.02	0.15	355.60	-0.98	356.58
Lev	2594	0.37	0.20	0.35	2.86	0.01	2.85
Cash	2594	0.24	0.16	0.20	0.93	0.00	0.93
Size	2594	15.72	9.29	20.83	26.65	0.19	26.46
Ret	2594	0.05	0.50	-0.02	3.89	-0.87	4.76

4.2 Regression analysis

In this paper, we went through the regression test to know how financial market environment influences overinvestment and underinvestment in the whole sample and each phases of lifecycle.

Here are the results on regression analysis of overinvestment in table 5. It is obvious that: to introduction, the more complete the financial market environment, the less the degree of overinvestment; to growth period, the more complete the financial market environment, the more serious the degree of overinvestment.

Table 5　Regression Analysis: Overinvestment

Variable	Total Sample	Introduction	Growth	Maturity	Decline
Financial	-0.015	-0.140	0.096	0.051	0.119
	（-0.455）	（-1.702）	(1.791)	(0.969）	（1.199）
Growth	0.006	0.015	-0.018	0.011	0.014
	-0.187	（0.193）	(-0.352)	（0.215）	（0.143）
Lev	-0.027	0.011	0.021	-0.150	-0.087
	（-0.702）	（0.130）	(0.350)	(-2.216)	（-0.790）
Cash	0.05	0.006	-0.02	0.12	0.102
	（1.314）	（0.073）	(-0.041)	（1.870）	（0.947）
Size	-0.099	-0.172	-0.044	-0.113	-0.013
	（-2.778）	（-0.1930）	(-0.782)	（-1.848）	（-0.113）
Ret	0.103	0.156	0.084	0.183	0.069
	（2.995）	（1.776）	(1.552)	（3.316）	（0.651）
Adj-R^2	0.326	0.412	0.258	0.321	-0.201

Here are the results on regression analysis of underinvestment in table 6. It can be seen that the more complete the financial market environment, the more serious the underinvestment in growth and decline. But the completing of financial market environment has no significant influence on other phases.

Table 6　Regression Analysis: Underinvestment

Variable	Total Sample	Introduction	Growth	Maturity	Decline
Financial	-0.015	-0.029	0.086	0.026	0.097
	（-0.455）	（-0.417）	（1.687）	（0.650）	（1.726）
Growth	0.006	-0.047	0.017	-0.011	-0.022
	（0.187）	（-0.730）	（0.347）	（-0.274）	（-0.387）
Lev	-0.027	-0.080	0.171	-0.140	-0.170
	（-0.702）	（-1.217）	（3.374）	（-3.071）	（-2.697）
Cash	0.050	-0.054	0.145	-0.023	-0.015
	（1.314）	（-0.808）	（2.791）	（-0.470）	（-0.230）
Size	-0.099	-0.033	0.050	-0.080	-0.167
	（-2.778）	（-0.477）	（0.905）	（-1.813）	（-2.628）
Ret	0.103	0.085	0.088	0.127	0.193
	（2.995）	（1.280）	（1.640）	（3.071）	（3.133）
Adj-R^2	0.226	-0.306	0.463	0.241	0.329

Generally, in the whole sample and all phases of lifecycle sample, the completing of financial market environment has different influence on overinvestment and underinvestment. Therefore, it is necessary to distinguish the lifecycle phases of the sample and to distinguish whether the sample is overinvestment or underinvestment.

4.3 Robustness check

We used China's Provinces Marketization Index Report's way to define financial market environment in this paper, and there are some other ways to define financial market environment in existing literature. Therefore, we will use the index of China's urban financial ecological environment

evaluation (2013~2014) to measure the financial market environment in 2012 and 2013. And the regression results are basically consistent with the previous ones.

5 Conclusion

Based on the financial data of the CSMAR database of 2010-2014 years' small and medium board listed enterprise, this paper studies the impact of the financial market environment on the inefficiency investment from the perspective of lifecycle. The results show that: (1) to the whole sample, completing the financial market environment has no significant influence on inefficient investment;(2) completing the financial market environment has different influence on overinvestment and underinvestment;(3) completing the financial market environment has significant worsening effect on inefficient investment to small and medium sized enterprises in growth;(4) completing the financial market environment can effectively restrain overinvestment in introduction;(5) completing the financial market environment has significant worsening effect on underinvestment to small and medium sized enterprises in decline.
Based on the conclusion, the following recommendations are made:

(1) Strengthening the governance of the financial market environment. The financial market environment in China is becoming more and more completed, but inefficient investment has not been restrained, there is a significant problem of the mismatch between the supply and demand of financial resources. Therefore, we need to strengthening the governance of the financial market environment, promote the rational allocation of resources, and improve the efficiency of investment.

(2) Pay attention to the economically underdeveloped areas. At present, there is an obvious imbalance on the development of the regional financial market environment in our country, and a considerable number of small and medium-sized board enterprises are in the area where the financial market environment is not superior. The optimization of the financial market environment in these areas can effectively promote the growth of local enterprises and the local economic development.

The limitation of this paper is that there is no agreement has been reached about the methods of dividing the lifecycle of enterprises, the quantitative methods of financial market environment and the inefficiency investment, and this paper fails to exhaust all the means of definition. In addition, limited by data collection, the samples in this paper are only financial data of small and medium size enterprises from 2010 to 2014, which may affect the results of the research.

Research on the Internal Control Process of Chinese Colleges and Universities under the New Situation: Based on Accounting Practice

Gao Zhenjing
School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: whutgzj@163.com)

Abstract: Internal control is the administration foundation of administrative institutions. This paper studied five subsystems of college budget, material procurement, monetary control, fixed assets and engineering projects in specific financial control links of colleges and universities. The internal control process of colleges and universities was constructed, and the key control points were summarized. The colleges and universities in the United States, the United Kingdom and China were compared to study the corresponding criteria and performance of internal control construction. The measures for internal control process improvement were proposed in the two dimensions of information disclosure and supervision management.This research aims to provide a feasible scheme for the construction of internal control system in colleges and universities and to provide guidance for effective financial risk avoidance.
Key words: Colleges and universities; Internal control; Control process; Financial risks

1 Introduction

Due to the expansion of autonomy and the increase of funding sources in colleges and universities, there have been frequent illegal and disciplinary violation behaviors in recent years. Colleges and Universities are the main institutions of national talent training, academic research and social service. In order to improve the operational efficiency of teaching and scientific research, ensure the safety and integrity of its property, and effective anti-corruption, the policies on regulating the internal control of colleges and universities have been published in succession. In 2014, the Ministry of Finance promulgated the Standard of Internal Control of Administrative Institutions, which defined the goals of internal control in colleges and universities, and opened the prelude to internal control system construction in colleges and universities. In 2016, the Ministry of Education formulated the Guidance to the Internal Control of Economic Activities in Colleges and Universities Directly under the Ministry of Education, emphasizing the main tasks of internal control in colleges and universities (Liu Ningbo, 2017) and pointing out the direction for perfecting the internal control system. Therefore, it is imperative for colleges and universities to strengthen the construction of internal control and carry out relevant research on financial internal control process.

At present, many scholars have carried out the research on internal control in colleges and universities. Daniel explored to relieve the benefit distribution contradiction between the internal control degree in colleges and universities and the use efficiency of financial allocations by establishing effective internal control standard (Daniel, 2005). Wang Weixing tried to construct the evaluation index system of internal control in colleges and universities, and established a fuzzy comprehensive evaluation mathematical model (Wang Weixing, 2008). David believed that including university internal control into cloud computing strategy helped to improve college budget control (David, 2010). Based on previous research, this paper studied five subsystems of college monetary control, budget, material procurement, fixed assets and engineering projects in specific financial control links of colleges and universities. The colleges and universities in the United States, the United Kingdom and China were compared to study the corresponding criteria and performance of internal control construction. This research results are expected to provide guidance for effective financial risk avoidance, improve their financial performance and implement the national policies.

2 Internal Control Process in Colleges and Universities

2.1 Budget internal control process

Budget preparation and approval. Budget preparation is the basis of budget control (Qiao Chunhua, 2015), and should follow the principle of "keeping expenditures within the limits of income and balance between income and expenditure". Budget approval is based on a clear post division. The examiners should carry out the examination and approval within the limits of their respective powers and shall not exceed their authority. The process is shown in Figure 2.

Budget implementation. The monthly financial allocation plan submitted by the second-level units should be strictly checked for the examination and approval procedures. A periodic reporting system is required in budget implementation. Each unit responsible for budget should follow up the budget implementation in time, analyze the existing problems according to the difference between budget and practice, and take active remedial measures.

Budget adjustment. The budget adjustment shall be approved by the principal office in accordance with the original budget approval procedure. Other departments shall make the decision of reducing or increasing the expenditure within their authority.

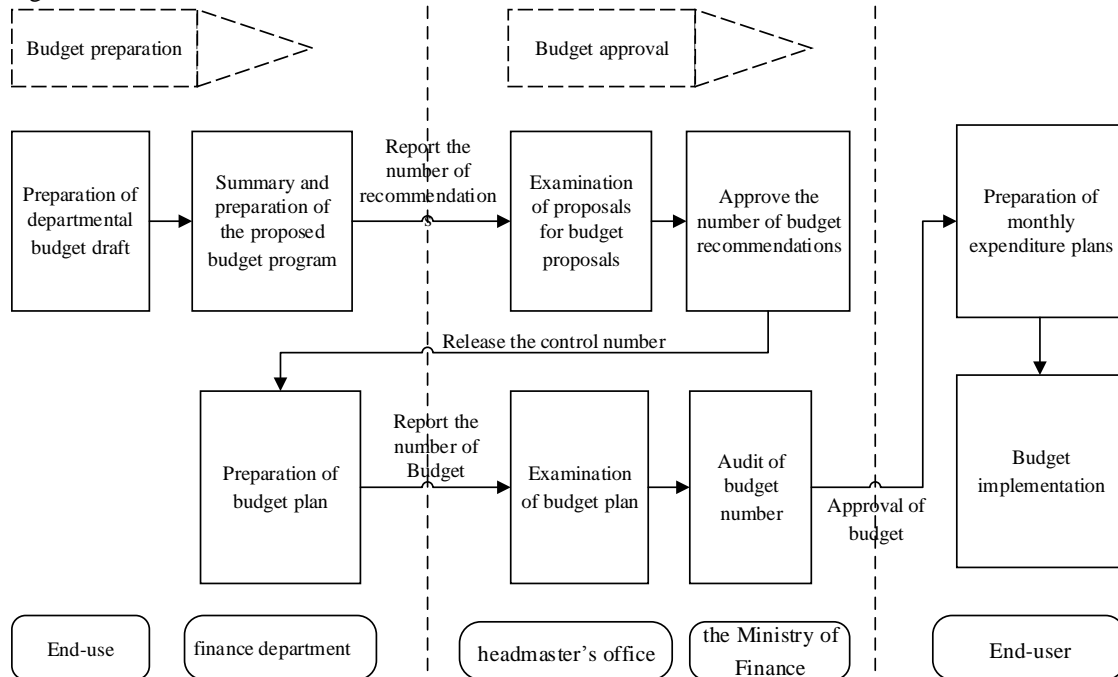
Budget supervision. The financial department should audit the implementation of the school budget at all levels, and include the results of budget income and expenditure audit and assessment into the annual assessment of responsible persons at all levels. The flow chart of internal budget control is shown in Figure 1.


Figure 1   Flow Chart of Internal Budget Control

2.2 Control process of material purchase

Post setting. Colleges and universities should set a special purchasing management organization or a management department to unify the management of material procurement business and improve the professional performance of the business (Zhang Zhaoxu, 2012). The post responsibility system is implemented, and the duties and powers of incompatible posts are separated. The personnel in the posts of purchasing budget approval, procurement execution, acceptance, contract management and payment perform theirduties, coordination, constraints and supervision.

Purchase approval. The use department and other relevant departments fill out the requisition according to the purchasing budget and actual demand. The purchasing department compiles the requisition and approves the purchase list. The hierarchical examination and approval system is adopted. The authority is granted according to the purchase amount to approve the funds, define the responsibility of the personnel at all levels, and ensure the safety of fund use.

Purchasing by invitation. The centralized purchasing mainly adopts public bidding, invitation bidding, competitive negotiation, inquiry and single-source procurement, among which public bidding is the main method. The colleges and universities should ensure that the bidding process is fair and prevent corruption by establishing the bidding committee and reasonably determining the pricing mechanism and the bid evaluation method and the information disclosure. See Figure 3 for detailed process.

Purchase acceptance. The receiving department shall control both the quality and quantity of the goods, accept the goods independently according to the contract requirements and issue acceptance documents or inspection reports. State-approved quality inspection agencies should be invited to participate in the acceptance process of large-scale purchase projects.

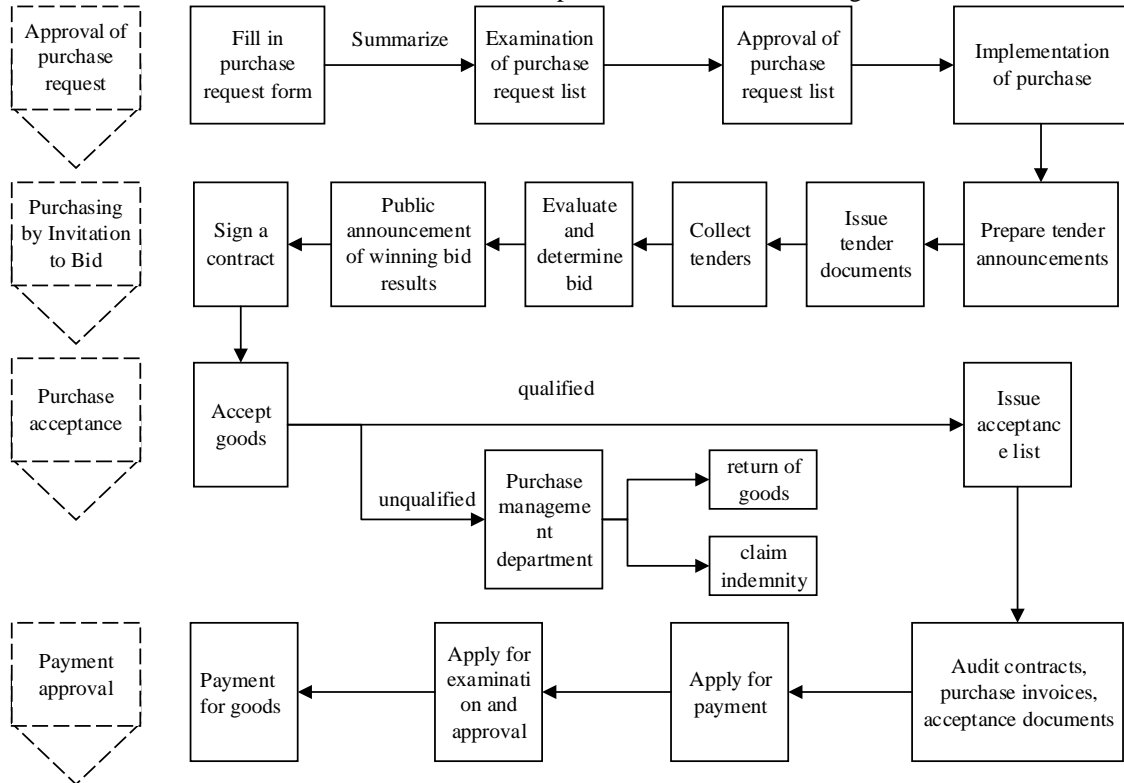
Payment approval. The finance department shall review the authenticity, validity and validity of contracts, purchase invoices, acceptance documents and other relevant documents, and pay the goods strictly in accordance with the cash management regulations. For large advance payments, tracking of procurement payments should be strengthened and final verification should be conducted on a regular basis. When there isabnormal money is, timely measures should be taken to recover the funds to avoid loss. The flow chart of internal control for material procurement is shown in Figure 2.


Figure 1   Flow Chart of Internal Control for Material Procurement

2.3 Internal control process of monetary capital

Application and approval. When handling cash business, relevant departments or individuals should submit the fund receipt and payment application to the approver in advance, indicate the amount, use approachand time, and show the valid economic contract or the related original certificate. The approver examines and approves the receipt and payment applications according to authorization. Collective decision-making and approval shall be carried out for matters belonging to "Three-Importance's& One-Large" system.

Receipt and payment review. According to the subordinate relation of the internal level in colleges and universities, review can be divided into longitudinal review and horizontal review. The former refers to the superior's review of subordinate activities, and the latter refers to the cross-review of persons with equal or no superior or subordinate relation. When reviewing the approved receipt and payment application, the reviewer shall review whether the scope of approval is correct and whether the receipt and payment business is true and legal. The cashier shall complete the receipt and payment formalities and register the cash and bank deposit journal for correct receipt and payment after review.

Account registration and check. The cashier registers a journal according to the receipt and payment voucher. The accountant registers the detailed ledger according to the relevant voucher. The competent accountant registers the general ledger after review. The auditor shall carry out account-voucher check, account-account check, account-chart check and account-actual amount check at the end of each month.

Cash counting. The cashier summarizes the economic operations of the day, settles the book balance of cash and reconciles it with the physical count. If the actual cash is below the stock limit, cash should be replenished in time. Otherwise, the excess part will be deposited in the bank.

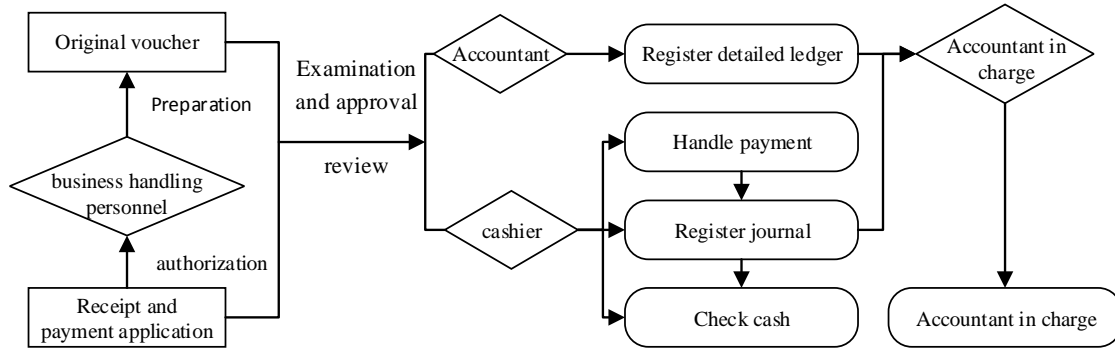
Note and seal management. Colleges and universities should make clear the procedures and duties of purchase, custody and use of bills, register records in a timely manner, and avoid false transactions of blank bills. The principle of separation of incompatible duties should be adhered to in seal custody. It should be strictly prohibited for a single person to keep the seal relating to the payment business (Zhao Zhihong, 2014). Seal and blank bill should be kept separately. The Flow Chart of Internal Control of Monetary Funds is shown in Figure 3.


Figure 2   Flow Chart of Internal Control of Monetary Funds

2.4 Internal control process of fixed assets

The fixed assets of colleges and universities refer to the assets with the unit value above the prescribed standard, the original material form of which is kept originally and the service life is longer than one year.The construction of internal control process of fixed assets is one of the key internal control in colleges and universities. In order to ensure the safety and integrity of fixed assets, the following control points should be grasped, as shown in Table 1.

Table 1   Key Control Points of Fixed Assets

Key control points	Specific contents
Budget control	Each end-user should prepare an asset acquisition budget after considering the asset stock, demand and acquisition standards. Personnel accountability should be implemented. The relevant budget personnel should be responsible for missing items, wrong items and other abnormal problems affecting the process of fixed asset acquisition in budget preparation.
Delivery and acceptance	The capital construction, asset management, user units and other related departments implement the acceptance and review the quality and quantity of fixed assets.
Receiving management	Colleges and universities should perfect the fixed assets account book registration system and card account, register the receiving behavior in time, ensure that the asset account, and realize the dynamic management of the fixed assets. In the case ofany loss or damage, the recipient shall be held liable for compensation in accordance with the corresponding system.
Periodic inventory	Colleges and universities should establish and improve the periodic fixed assets inventory system, grasp the use of assets in time, avoid the damage and loss of fixed assets, and ensure the integrity and safety of fixed assets.
Scrap disposal	When the fixed assets are scrapped, the "fixed assets scrapping form" should be filled in, and the use of the fixed assets and the reasons for the abandonment should be explained. The asset management department clears the fixed assets according to the approval result and cancels the fixed assets card account.

2.5 Internal control process of engineering project

Project decision making. Firstly, the engineering project planning is generally compiled by the investor or the capital construction departments. Secondly, the finance department proves the feasibility and necessity of the project planning based on the quantitative and qualitative dimensions, issues the feasibility report, and finally implements the collective decision.

Budget control. The professional staffs of the capital construction department and the finance department of colleges and universities should strictly examine the preliminary planning and budget estimates of the engineering projects, particularly whether the compilation basis, project contents and quota application are true, scientific and reasonable. The amount of project investment shall not wantonly exceed the approved project estimate. If adjustment is required, it shall be submitted for

approval according to regulations.

Engineering project tender. Colleges and universities should adopt public bidding to select the units of investigation, design and construction of engineering projects, and employ professional evaluation organizations to evaluate the bids and prevent unreasonable winning bids.

Engineering construction. The financial departments of colleges and universities should strengthen the control of project progress payments and implement the system of "two pens" countersigning for payment of project funds (Niu Yanfen, 2011). The capital construction department shall regularly submit the project schedule and project price settlement statement. After the budget personnel, the capital construction department and the project price payment examiner have examined and approved the project price payment, the financial department shall further check the settlement information.

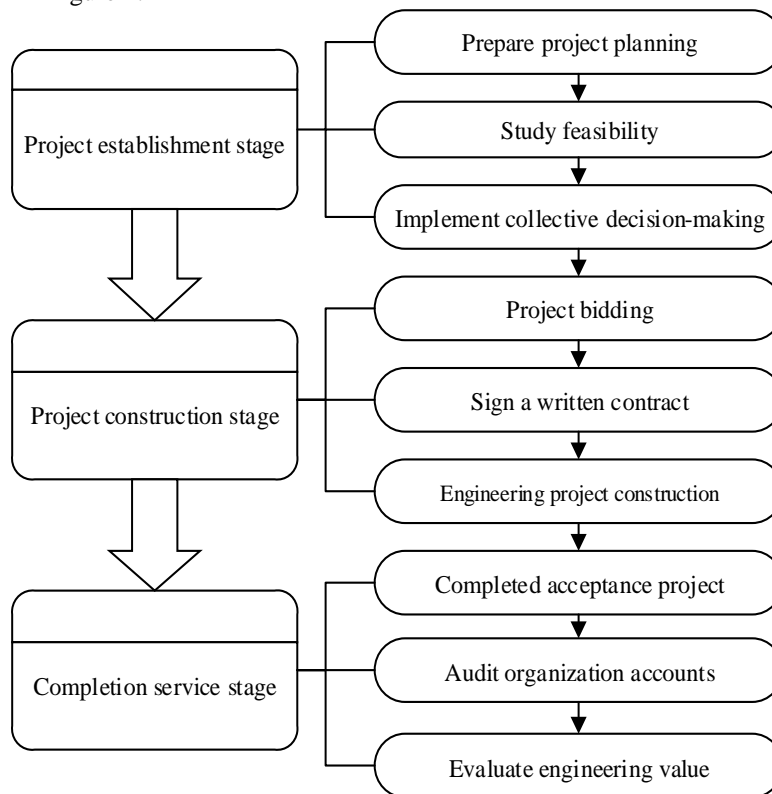
Completion and acceptance. After project acceptance, colleges and universities should complete the final accounts according to the prescribed time limit, organize the final accounts audit, and evaluate the project value after completioning of the project. The Flow Chart of Internal Control for Engineering Project is shown in Figure 4.


Figure 3   Flow Chart of Internal Control for Engineering Project

3 Comparison of Internal Control in China, the United Kingdom and the United States

In this paper, the internal control guidelines published by Oxford University, Harvard University and Peking University on their websites were taken as the samples. Limited by the availability of information, comparison is only made in three aspects: capital supervision, budget and fixed assets. It is found that standardized internal control process and effective implementation mechanism have been established in the developed countries with relatively perfect internal governance structures such as the United Kingdom and the United States, and they have relatively perfect internal governance structures. Sound performance appraisal system or risk management has not been established in Chinese colleges and universities. There are still some problems such as unclear division of labor and ambiguous power and responsibility in various functional departments.Detailed comparison is given in Table 2.

Table 2   Comparison of Specific Internal Control Regulations

Specific regulations	Oxford University	Harvard University	Peking University
Monetary fund control	Budget Subcommittee of the Planning and Resource Allocation Committee will receive and keep under review the five-year plans of income, expenditure and capital commitments for the University Administration and Services and the Academic Services and University Collections division	Schools must regularly monitor the fees for restricted funds. School supervision using the centralized approval model shall include analytical reviews; the use of a decentralized approval model shall also include transaction sampling.	Whenever a large amount of money is involved, the financial officer should handle it according to the specific approval content within the duty scope.
Expenditure budget	Every instance in which a budgetary unit is allowed materially to exceed its budget must be reported to the next meeting of PRAC by the parent body or by the relevant divisional board.	OSP implements cost management in accordance with the cost management principle and divides the budget for project scientific research into direct costs and indirect costs.	Under the leadership of the principal in charge, the Finance Department is responsible for supervising and controlling the implementation of budgets at all levels of the school and reporting budget execution to leaders at all levels on time.
Fixed asset	The purchase, leasing, or sale of all real property owned or leased by the University, which is not held as an investment, must be authorized by PRAC.	When the loan term of a componentized building is required, it shall be ensured that the loan term does not exceed the weighted average service life of all components in the project.	At the end of each year of fixed assets, the equipment management department, the financial department, and the use department must jointly conduct an inventory, so that accounts, materials, cards, and fund can be matched.

4 Suggestions and Enlightenment for Chinese Colleges and Universities

Information publicity is not only an important measure to promote colleges and universities to run schools and manage financial affairs according to law, but also a major way to promote the openness and transparency of the fund use and management in colleges and universities. Firstly, the information communication channels in colleges and universities should be perfected. Although many colleges and universities have set up the open information network for the public, it is virtually empty because of its selective publicity. Colleges and universities should further refine their active open scope and increase information disclosure in areas such as recruitment, finance and infrastructure so as to realize open operation and eliminate corruption. Secondly, the information communication platform should be established in colleges and universities, and the cooperation mechanism of each department should be perfected (Wang Chunjv, 2016),to solve the problems of self-made system in each department, realize the information exchange and sharing (Xi Zunxiao, 2010), and improve the operation efficiency.

Chinese colleges and universities lack the examination on budget implementation and benefit investment. There is the problem of insufficient risk management (Liu Gang, 2018). Therefore, colleges and universities should refine the performance evaluation index system (Yan Meirong, 2016) and set up a risk assessment team to analyze the risk points in each process and post, formulate risk countermeasures, and pay attention to scientific and effective resource management. For example, colleges and universities can set performance indicators of expenditure on funds, evaluate the

effectiveness of budget control, give material rewards to schools that have excellent performance in fund management, and encourage them to invest in the teaching staffs and the construction of educational resources. Meanwhile, the risks of expenditure activities should be evaluated systematically and objectively evaluated, and corrective measures and suggestions should be put forward.

5 Conclusion

Based on the theoretical basis of internal control, this paper summarized the internal control process for monetary fund supervision, fund budget, material purchase, fixed assets and engineering project in colleges and universities. The key control points weredivided reasonably to provide a feasible scheme for the construction of internal control system in colleges and universities. According to the comparative results of the specific internal control regulations in three universities of Oxford University, Harvard University and Peking University, this paper puts forward the countermeasures of strengthening the disclosure of information, perfecting the risk management and enhancing the performance appraisal system in Chinese colleges and universities so as to improve the efficiency and effectiveness of internal control. However, there are still some limitations in this paper. Due to difference in scale, specialty and system background of each university, the universality of the internal control process constructed in this paper is unknown. Therefore, colleges and universities are suggested to further explore their own particularities. In addition, limited by the availability of information, this paper only studied the construction of internal control processes in five aspects: capital supervision, budget, material procurement, fixed assets, and engineering projects, and the involved scope is relatively narrow. Other researchers can further explore the basis of this research.

Abstract: Introducing the risk management into the college students' affair department has become an important method. In the process of students' affair risk management, ideological guidance has its value in colleges and it should be emphasized and studied in the management of students' work risk. In the management of students' affair risk in colleges, it is necessary to give full information for ideological guidance in stage of the risk of pre-treatment; to clarify the misunderstanding on the matterin stage ofRisk management stage; to rehabilitate the emotion and to risk re-education in the stage of risk management later.

Key words: Students affair; Risk management; Ideological guidance; College students

1 Introduction

In recent years, college students have frequent emergencies, which have taken great challenges to college students' affair. Introducing the risk management into the college students' affair department has become an important method.

Inabroad, Entering the 1990s, systematic security and non-traditional security theory emerged(Siegel D,1991). Crisis management began to enter the field of public administration and entered the campus. As the development of the event is a dynamic process, and the development of the situation is constantly affected by the internal and external environment (Landman, 2015). More and more attention is paid to the early warning of emergencies (Garc á J P, 2005). The management scholar proposed the crisis life cycle theory, that is, the crisis factor from emergence to the end of the process of the emergence of different life characteristics, such as the birth, growth, maturity to death of the biological process.Robert Heath proposed the "4R pattern" of crisis management (including Reduction, Ready, Response, and Recovery). As the development of the event is a dynamic process, and the development of the situation is constantly affected by the internal and external environment, and the development of the event affects the internal and external environment constantly, so the emergency manager of the university should not only input the historical information to the system, but also constantly input the updated real-time information to the system (Silverman,2014).

On the domestic research, students' affair risk management started earlier than in China.The awareness of early warning is insufficient, and the passivity is strong. The early warning plan is the main content of early-warning management, and the early warning lacks scientific guidance.The goal is to control the development of emergency, and to prevent and eliminate the occurrence of emergencies as much as possible and try to minimize the risk of sudden events on people and property. The management scholar briefly summarized the university student group emergency management mechanism as "three stages" and "four mechanisms"(Qiu Kai, 2007). The "three stages" concretely refer to three stages, namely, the pre-management stage, the event management stage and the post management stage. The "four mechanisms" refer to four mechanisms of early warning mechanism, evaluation mechanism, processing mechanism and feedback mechanism.

At home, the present situation of the early warning research of mass emergency in Colleges and universities is that the awareness of early warning is insufficient and the passivity is strong, and the early warning plan is the main content of early warning management, and the early warning is lack of scientific method guidance. The contingencies plan for unexpected incidents in Colleges and universities is an important part of the early warning mechanism. The goal is to control the development of emergency, and to prevent and eliminate the occurrence of emergencies as much as possibleand try to minimize the risk of sudden events on people and property. Aboveall, ideologicalguidance has its valuein the process of setting up students' affair's risk management (Zhang Yaocan, 2006). The process of students' affair's risk management should be divided into three stages: the early stages of risk management, the current period of risk management and the later stages of risk management (Tang Jun, 2010), as it's shown in Figure1.The basic functions of the early warning system of University emergencies can be reduced to monitoring function, information analysis function, preventive function

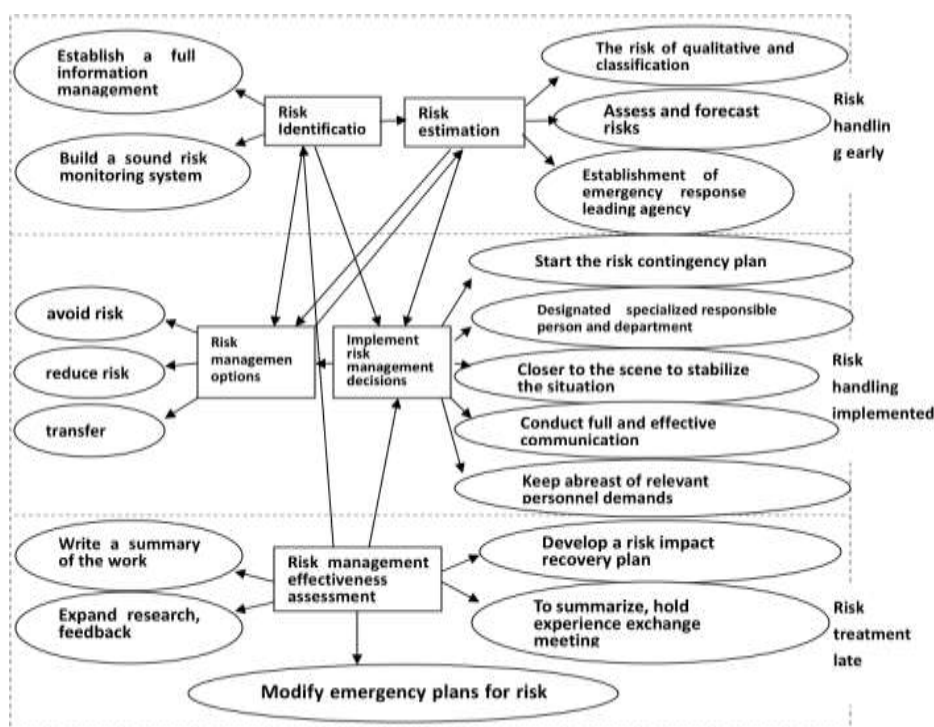
and communication function.


Figure 1   College Students'Affair Risk Management Stage

2 The Function of Ideological Guidance in the Stages of Risk of Pre-treatment

In the stages of risk of pre-treatment, the main tasks are identification and estimation. The objective is to minimize or eliminate the possibility of risks. The measures mainly include actively prevent, eliminate incentives, intervene early, persist in persuasion and so on.Pre-risk management, including risk identification, risk assessment. At this stage, the core element of student affair risk control is the control and management of information and information, which are important tasks of this class. At this stage, focusing on the core element is information. Ideological guidance should focus on information (Dance R, 2014).

2.1 Information collection

Educators can effectively collect and control student thoughts and behavior and other information, and identify risks based on the information. In the field of Ideological guidance, thoughts and behaviors are the most important category. The occurrence and development of social events can lead to the change of students' thinking, and the thoughts and behaviors transform into each other. The daily ideological guidance workers in colleges, including counselors and class teachers, have the most contact with students and are most familiar with the students 'living conditions. They can detect the students' various ideological fluctuations in time and observe the behavior changes of students (Zhang Yaocan, 2006).

In practice, in the students' affair risk management system of colleges, counselors contacting with students are regarded as the based organizations. Including the establishment of daily Ideological guidance risk awareness, enhance risk identification capabilities, smooth its risk communication channels, standardize the operation of communication standards and processes. Relying on professionalism and skills, educators often timely and effectively collect information. Counselors and class teachers, in a broad and intimate contact with students, can grasp the student's ideological trends, timely detection risk and hidden dangers. Especially with the development of the wireless network, the use of big data collection advantages, timely capture of information to make predictions. Risks should be promptly notified, so early warning, standardized forecast, in order to promptly take emergency measures.

2.2 To resolve potential risks

In the stages of risk of pre-treatment, we should make full use of the leading role of Ideological

guidance to guide the values of college students, to avoid the drastic fluctuations of thoughts and emotions, effectively to prevent the occurrence of incidents situation. Students' affair risk is usually manifested from the students' tiny thoughts and behaviors, and then brought together into larger contradictions and conflicts, resulting in adverse effects.

In the face of external difficulties and internal confusion, counselors and class teachers,who is supported by the specialized knowledge system of the Ideological guidance, can find out in time and resolve the students' ideological confusion. Students should be encouraged to cultivate correct values in all kinds of contradictions and conflicts. In the end, students should not be confused by external thoughts, not under the control of your own passion, and learn how to deal with things correctly. In this way, ideological guidance has the function of further evolution to solve potential risks and avoid causing crises, in the stages of risk of pre-treatment.

In practice, the students' affair should be treated according to the institution, which is the best way to prevent crisis. Specific methods to implement function are to develop and implement risk management training programs for front-line educators, to improve the awareness of risk prevention, to learn theory both the risk management and ideological guidance. Educators should be encouraged to using methods, such as listening, career planning, psychological interview and counseling and so on. It can broaden students' vision, regulate their emotions, and guide students to change their behaviors.In this way, ideological guidance makes true of functional implementation on enhancing students' subjective judgement of potential risks and increasing their confidence in resolving potential risks. It is necessary to establish an information notification system and early warning system, including the type of information to be notified, the requirements for communication of different risk levels, the notification feedback process, etc... If there is sufficient awareness of early warning, there are certain ways to prevent risks and a more complete early warning system, the risk of occurrence will be greatly reduced.

3 The Function of Ideological Guidance in Stage of Risk Management Stage

In stage of risk management stage, the main task is the disposition, including risk management and risk management decision-making. The objective is to minimize the risk possible hazards. The measures mainly include process management, coordination and communication, situation circular and so on. Once a risk event occurs, it promptly initiates the plan and adopts a risk control strategy. The aim of this stage is to increase the capacity in the operation and the handling of events for the risk management organization. Ideological guidance should focus on the following functions in stage of Risk management stage.

3.1 Unifying thought

Ideological guidance can produce the unity ideas of students' affair risk management, to improving efficiency and effectiveness crisis management. It has different opinions on the analysis of risk management and the choice of tactics on usual. The disunity of thinking is the most unfavorable to achieving the objective of students' affair risk management. To realize the expected effect of risk management, we must enhance the thought unity in the process of risk management. In the risk event, colleges must start-up risk controls, enhance the thought unity bothrisk managers and object. In this process, it must stimulate their subjective consciousness to achieve risk management's aims. At the same time, the unification of ideas is also the essential function of ideological guidance (Z Christian Uhr, 2008). Another way of saying is that the management of students' affair risk in colleges is the function of the subject of Ideological guidance,in stage of risk management stage.

In practice, it must clear and clarify aims at students' affair risk managementin three groups of groups which are includingcommand layer, executive layer and management object. In this way, command layer, executive layer and management object control object could unity ideasfor crisis management. On the base of the risk assessment, the command layer must make clear the general objective and formulate a scheme of the students' affair risk management. At the same time, to prompt the publicity must be taking by means of conferencing or instant messaging to facilitate the risk management, in order tounify participants' thinking. The executive layers have duty on makingaimknown and clarify to participants, taking part instudents' affair risk management while using the method of target analysis. The risk management aimstoset the basis for all their actions, in order to deal with all the circumstances in the risk. If all the executive layers would work together on the same aim, it will be on optimal state. On the layer of management object, all the participants need to do a good job propaganda and explanation of risk management aims, strive for the spread of the crisis and

may affect the group's understanding, won the support of public opinion, and create a good external environment for risk management.

3.2Psychological counseling and humanistic care

The psychological counseling and humanistic care is the main function of Ideological guidance. It can effectively arouse the awareness of students to participant into students' affair risk management, which could maximize the effectiveness of risk management. Ideological guide is good at psychological counseling and humanistic care,compared with students' affair risk management. In the students' affair risk management, the students'behavioris usually limited by the rule, accompanied by passive attitude. At this situation, it failed to get the understanding and recognition of students at all. To a certain extent, it would be a new hidden danger. At the same time, Ideological guidance use psychological counseling and humanistic care to calm down negative emotion and to solve various conflict and perplexity, so that the students are cultivated morality and values advocated by the state.

In practice, the ideological guidance must pay attention to "Soothing" and "guiding" two links. "Soothing" refers to psychological counseling and humanistic care, through the appropriate way to make the target more objectively aware of their selves feeling. Firstly, Ideological guidance needs to make students' emotions tend to be rational peace and mental state in crisis by the way of conversations face to face. Students would have intensive experience that there is someone understood and care for his or her feeling. Once students get the belief that more than one solution to difficulties and problems in the crisis,students could return to calmness and reason. "Guide" refers to guide and inspire methods, in order totransmittingthe positive value to students. Ideological guidance workers focus on guiding students in crisis, try to clarify and adopt reasonable ways to deal with the plight and give support to making students out of the crisis.Through the organic combination of "Soothing" and "guiding" two links, the students in the crisis can be transformed in a thoughtful way, form the correct world outlook, outlook on life and values, and reach consensus on the concepts and goals with students'affair risk management workers. Fundamentally, it can work by students'affair risk managementon the side of ideology root.

4 The Function of Ideological Guidance in the Later Stages of Risk Management

In the later stage of risk management, the main task is the evaluation of risk management effectiveness. The objective is to recovery after a risk event. The measures mainly include psychological comfort, material remediation, feedback and so on. In the later stage of risk management, colleges must take the measures of assessing the effectiveness of students'affair risk management, formulate the risk impact recovery plan, evaluate the effect, and summarize the experience to correct the contingency plans for risk events to provide reference for future risk management and decision-making and improvement of management. At this stage, risk control mainly focuses on the recovery after the risk, Ideological guidance should focus on the following functions.

4.1Emotional recovery

Colleges should focus on giving full play to the repairing function of Ideological guidance in the later stage of risk management of students' affair and do a good job in the emotional repair work of people involved in crisis events. In the later stage of risk management, it is relatively easy to repair the physical loss. However, the crisis events often make students and college workers and teachers psychological trauma, resulting in the deviation of normal behavior. For psychological rehabilitation work, colleges should actively carry out Ideological guidance, with particular emphasis on restoring the psychological trauma of direct impactors, adjusting the mood swings of related objects and eliminating the psychological negative effects caused by the risk treatment to the greatest extent.

In practice, emotional repair requires educators pay attention to those, who were directly affected and who were involved. Ideological guidance workers should take the initiative to psychological impact of risk on the parties and witnesses and make proper use of methods of mental health and assessment. According to the actual situation, effective psychological consultation and treatment are given to the negative emotions in risk management. Especially, psychological trauma rehabilitation and long-term follow-up counseling are required.The emotional repair work of relevant people should be reach consensus on the handling of crisis events, by psychological communication in a timely manner. At the same time, through the ideological guidance to achieve the elimination of psychological shadow and to maintain the security and stability of the campus.

4.2 Risk re-education

Colleges should pay attention to reeducation of ideological guidance in the latter stage of students'

affair risk management. Risk re-education is education with the actual casein a timely manner. Every occurrence of a risk event is a lesson; every risk handling is a process of accumulation of experience and learning. In a timely manner to carry out ideological guidance, with vivid examples of the narrative and commentary, so that managers and objects will be better understand the risks and guide students to form a correct outlook on life, values and world outlook and good moral character, personality accomplishment, to avoid Risk events happen again.

In practice, the risk re-education of ideological guidance should be given to both re-education of risk control personnel and the re-education of students. At the re-education of risk management, the risk control personnel should be organized to evaluate the management and control implementation process, identify the risk point in control operations, optimize the risk management plan and so on. It is up to trainstaff of risk management learning from real cases to promoting overall ability to deal with crisis.To compile internal data on risk events and their processes，to optimize the exist risk emergency treatment system，to summary management method and keep pace with the times, which are optimum selection for train staff by the risk re-education of ideological guidance.To compile the risk events into a case to educate students vividly and timely in the process of student re-education is the responsibility of Ideological guidance. Having done these tasks, an important link of "turning crisis into opportunity", which are more important to help students to establish a correct outlook on life, world outlook and values, which ultimately implement the basic mission of education.

5 Conclusion

In the process of students' affair risk management, ideological guidance has its value in colleges and it should be emphasized and studied in the management of students' work risk. In the management of students' affair risk in colleges, it is necessary to give full information for ideological guidance in stage of the risk of pre-treatment; to clarify the misunderstanding on the matterin stage ofRisk management stage; to rehabilitate the emotion and to risk re-education in the stage of risk management later.

Abstract: As an important part of educational business in China, non-governmental education plays a significant role in the cultivation of talents and the development of science and technology. This paper uses the qualitative and quantitative research methods to analyze the problems of internal governance structure, such as the imperfection of system and party construction work, the lack of education resources and the unscientific management of faculty. Based on the analysis, it proposes new paths for the development of non-governmental education and provides theoretical support for operation and management of non-governmental education.
Key words: Non-governmental education; Institutional system; Party construction; Internal governance structure

1 Introduction

With the continuous development of the economy and society, the main contradiction in society has changed. The public's demand for education has increased, requiring education to be diversified, quality-oriented and personalized. However, the development of educational undertakings is uneven, the development of different stages is not balanced, and the quality of education is not fully developed, which cannot meet the current multi-level needs of education. The transformation of government system and functions makes the limitations of public education in the process of providing educational services more and more obvious. (Thomas Baumann, 2013). Non-governmental education has the natural advantages of social strength, flexible system and strong social factors. As an important part of Chnia's education, it will be able to be more sufficient in releasing resources, optimizing structure, enhancing efficiency and cultivating the efficiency. (Zhou Haitao, 2017) It plays an increasingly significant role in improving the quality of education, optimizing the structure of education, and promoting fairness in education. The relevant laws of the country have been continuously improved, and the development of private education has also been elevated to a new height. This provides a historical opportunity for exploring the internal governance of non-governmental education and exploring new internal governance models. The high investment of public finance in education will attract society investment, increase social donation and promote the healthy development of education. (Calin Arcalean, Ioana Schiopu, 2016)

2 the Development of Non-governmental Education in China

"Non-state Education Promotion Law of the People's Republic of China (2016 Revision)" defined the private education as "Schools and other educational institutions which are runned by any public organs or individuals, except for the state organs to meet the demand of the society by utilizing non-statefinacial funds." Originated in the 1980s, China's non-governmental schools made up for the lack of funds and capabilities of the government in education by providing education service. According to "Statistical bulletin for the development of social services" from 2014 to 2017 (Figure 1), the number of non-governmental education   has increased year by year and the growth rate has remained stable, reflecting that China's non-governmental education has a good development trend and has made up for the insufficient resources of public education. From the perspective of the external macro environment, non-government education has great room for survival and development. It conforms to the economic and social development of China, the reform of the government system and the expanding demand for educational services. The government actively encourages and supports non-governmental education and continuously improves the supporting conditions of policies, funds and projects,so that it has good environment and guarantee for its survival and development. From the perspective of the internal governance environment, China's non-governmental schools mainly adopt the principal responsibility system under the leadership of the board of directors, which can improve the enthusiasm of social investment of non-governmental education, promote social attention and support for non-governmental

education. However, the development history of the board of directors is relatively short in China. Simply imitating the west has deviated from the reality of the development of China's non-gvernmental education, which has seriously affected the self-development.
Figure 1   Non-governmental Education in Recent Years（unit: thousand）

3 Internal Governance Dilemmas of Non-governmental schools

3.1The imperfect institutional system

Improving the internal governance structure of legal persons and establishing a modern school system is the basis for the standardized management of non-governmental education. (Zhou Haitao, 2014) The existing laws and policies lack specific regulations and guidance for the principal responsibility system under the leadership of the board of directors, resulting in the lack of corporate governance institutions and operational mechanisms for non-governmental education in China. Non-governmental education varies greatly depending on time, location and policy scope. (Daniel C. Levy, 2016) Teaching quality and teaching management are the lifelines of running a school (Wang Dong, 2015), the key of improving teaching quality and strengthening teaching management is supervision. The imperfection of the internal self-regulatory mechanism of non-government education and the unclear definition of property rights have led to poor implementation of the organizational management system.(Luo Jun, 2015) Most of them lack supervisory institutions and supervision mechanisms. Due to the lack of funds for education, there are frequent violations of school-running scope, malicious charges, scattered false advertisements, and crowdfunding. Taking the income of education funds for private colleges and universities in 2017 as an example (figure 2), business income accounts for 80.7%, of which 73% comes from tuition and fees income, and 11.6% in national fiscal education funds. In view of this, they can only be market-oriented in order to survive, and gain social reputation by cultivating practical talents. This "bottom-up development path"(Yan Fengqiao, Lin Jing, 2012) leads to the power   decision-making, execution, and supervision are relatively concentrated or excessive, which in turn affects the autonomy and self-discipline of private colleges and universities.
Figure 2   the Income of Education Funds for Private Colleges and Universities in 2017

3.2 The defective governance structure

Influenced by the organizational form of the enterprise, non-governmental schools investors have a large proportion of the right to speak, which has seriously affected the teaching of the school. The corporate governance system of non-governmental schools needs to form operational mechanisms inclouding authority, decision-making, supervisory, and executive agencies. In theory, between the authority mechanism and the decision-making mechanism is the principal-agent relationship, between the decision-making mechanism and the executive agency is the authorized management relationship. The independent operation of the supervisory mechanism can ensure the benign operation and

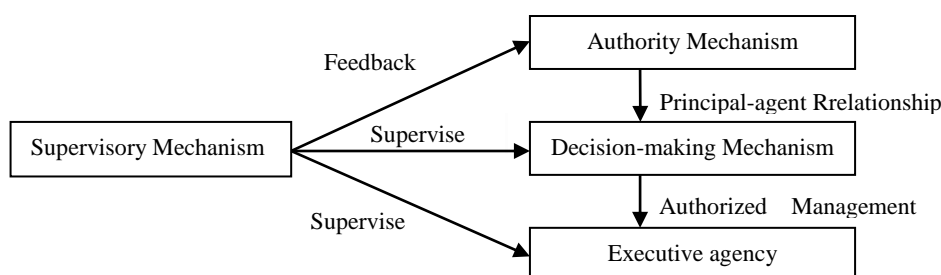
development under the mode of multi-study. (Figure 3) Affected by the government's management functions, non-governmental schools have become a subsidiary of the government to a certain extent. (Ma Pengwei, 2013) From the education of teaching to the allocation of enrollment, from the appointment of cadres to the remuneration of teachers, they are managed by the higher education administrative department. (Sui Xiangping, Song Tingting, 2016). Light supervision and heavy management of government to the non-governmental schools are not only the restriction and control for principal responsibility system under the leadership of the board of directors, but also the barriers to Innovate teaching methods and display school characteristics. The rigid management model of schools cannot stimulate the flexibility and autonomy of teaching and running schools, resulting in relatively concentrated or decentralized decision-making, execution and supervision power. The weakening of internal supervision of schools, especially the existence of loopholes in decision-making execution and management, has resulted in the educational status of "no features of teaching, no characteristics of school, and no special skills of students".（Chen Mingtong, Chen Peijun，2017）


Figure 3　Non-governmental Schools Internal Management Model

3.3 The unscientific faculty management

According to "Statistical bulletin for the development of National education business" from 2012 to 2016(Figure 4), compared with the public schools, non-governmental schools generally have the problems of the lack of teachers and the instability of the faculty. At the social level, China's market economy starts relatively late, and the construction of social organizations' integrity is at the primary stage. Some teachers of non-governmental schools have low barriers to entry and lack effective supervision and management. Many malignant cases such as Nan yang education group, private kindergarten abuse and internet addiction school cause strong social reaction so that people are skeptical to non-governmental education. From the government level, the guidance of government to education is extremely important. The government should pay more attention to the practicability of education for adapting it to the current economic environment. (Allan O'Connor, 2013) The insufficient investment of government's livelihood projects and financial funds has led to serious funding problems of non-governmental education, the lack of guarantee of teachers' salary and the insufficiency of teaching facilities and treatment. From non-governmental education level, low quality of the managers whose internal management and distribution policy are unreasonable. They cannot implement rewards and punishment incentive policy, which lead to more weaken teachers' teaching motivation and serious brain drain.
Figure 4　Teachers in Non-governmental Schools and Governmental Schools　（unit: billion）

4 Internal Governance Strategies of Non-governmental Schools
4.1 Perfect the system

At the legal level, the state has continuously improved the support of non-governmental schools, which provided the policy and legal basis for the development of private education. First of all, it is necessary to clarify the ownership of non-governmental education and establish the legal subject status of non-governmental education. According to the legal requirements, government should formulate the implementation rules for the classified management of private education and guide non-governmental schools to give the priority to the social benefits. Secondly, the essence of corporate governance structure is the scientific distribution and mutual restriction of power and responsibility within the organization, so that the organization can achieve the set goal.(Liu Jingyang, 2016) Non-governmental schools should improve the principal responsibility system under the leadership of the board of directors and form an non-governmental education structure with Chinese characteristics including the decision-making system, the consultative system, the executive system and the supervisory system. In addition, it is necessary for non-governmental schools to implement a unified and standardized accountability mechanism, improve the internal management system and improve the self-restraint mechanism, which in order to make up the loopholes in the current internal management. Formulate and improve the internal management rules and regulations including the accounting system, personnel management system, meeting system, file management system, form a complete and orderly management system to enhance the feasibility and effectiveness of regulations and lay the foundation of development of non-governmental schools.

4.2 Strengthen supervision

The main leaders are in charge of setting up a leading group leading group including financial, auditing, and others to participate in the internal control, quicken construction of internal control system and ensure the institutionalization, regularization of the internal supervision system. (Yang Zhaohui, 2017) Non-governmental schools need to maintain the independence of internal supervision and set up a scientific and reasonable system of budget, review and settlement around financial management for ensuring the disclosure of financial information. They should intensify the examination of teachers' qualifications, find out and solve teachers' academic misconduct in a timely manner, maintain the healthy development of the teaching of non-governmental schools. Furthermore, non-governmental schools shall enlarge the breadth of supervision and provide teachers and students with supervision methods and approaches, set up special reporting channels and form the bottom-up and top-down combining the internal supervision mechanism. At the same time, with the aid of third party supervision mechanism, non-governmental school ought to establishment a unified examination standard to carry out comprehensive supervision and evaluation on non-governmental schools and within the industry to set up rewards and punishment mechanism make public periodically to the public. Non-governmental colleges and universities should further promote education management evaluation and separation and improve the education evaluation system of multiple entities and the academic integrity status. (Lu Yao, 2017)

4.3 Improv the faculty management

The author suggests that strengthen professional training for employees and improve the employment system, it's also should raise barriers to entry for industries and reduce the deterioration of teachers at the source. Non-governmental schools should enlarge the coverage of party construction and set up party organizations at the grass-roots level, similarly, should pay attention to strengthen party member's education and develop party organization's fight fortress function and the general party member's cutting edge exemplary role. There is no doubt that enough concern must be paid to cultivate the values of "education first" and transform the personnel system of education institutions and improve teaching staff's importance to teaching. The school leaders should follow education rule, implement the operation and management mode consistent with education essence and return to education standard. It's also essential to fully respect the opinions of teachers and students, and concentrate the wisdom of the group. Non-governmental schools shall improve the salaries and benefits of non-governmental education staff and formulate incentive and guarantee policies for enhancing the professional identity of faculty and staff and stimulating the vitality of teaching. To maintain the healthy and orderly development of the school, organizers and managers of non-governmental schools should improve their scientific management level and expand the extent for school-running autonomy. Meanwhile, actively search the funds, policies, and resource that is good for school development and education public services.

4.4 Seek external support

Government should respond to the provisions of the law and actively formulate financial support policies and preferential tax policies that meet the development of non-profit private schools, plan the relationship between governmental education and non-governmental education. Non-governmental schools should expand the channels of income generation under the guidance of the government to

maintain the sustainability of their own development and release the vitality of running schools and lay a foundation for improving the quality of running schools. They should form an internal and external supervision system to maintain the sustainable and healthy development of non-governmental schools. The external supervision which is coordinated by the supervision of the news media, the supervision of the private education industry, the supervision of the relevant civil affairs departments of the government, and the supervision of the public should be formed. Non-governmental schools need to use social media and public opinion to enhance their social influence and publicize the social value of non-government education. It's also need to raise public awareness of non-governmental schools to form a good social atmosphere and stimulate the enthusiasm of the society to invest in education.

5 Conclusion

Non-governmental schools are an important driving force for the development of China's socialist education. They solve internal operations management problems of the current through improving the internal system, strengthening internal supervision, improving the level of teaching management and seeking external support help. The transformation of the main contradiction of socialism with Chinese characteristics in the new era reflects the great gap between the demand and supply of education public service. It is of great significance to actively explore the development of private education, but the road of the healthy development of non-governmental schools is still long. The internal and external governance system of non-governmental education needs to constantly improve and innovate, which requires coordination and cooperation from the government, non-governmental schools, society and other aspects.

(E-mail: wuxc9455@163.com, 506111552@qq.com, 462616978@qq.com, 648610843@qq.com)

Abstract: In recent years, many mass events have brought adverse effects to the peace and harmony of the society, and also brought great pressure to the government. From the perspective of group psychology, this paper focuses on analyzing the five psychological sources of irrational behavior of the group by restoring the process of its production: self-categorization leads to deindividuation of group members, bandwagon effect of individuals under the influence of information society, relative deprivation caused by psychological frustration, high cognitive dissonance of group members, and the fluke mind of "The law cannot be enforced when everyone is an offender". Meanwhile, it is recommended that members of the society establish a sense of crisis, and make full use of the power of the media and the government to build early warning and emergency mechanisms to reduce the occurrence of mass events.
Key words: Population; Irrational factors; Psychological; Mass events

1 Introduction

In terms of quantity, the absolute number of mass events in China has increased from 80,000 in 2007 to 139,000 in 2011. By 2014, this number reached 172,000. Although there is a lack of statistics on data after 2014, However, according to the "China Social Mass Events Analysis Report" published by Professor Zhang every year (Zhang,et.al, 2017), the mass event "has not undergone a fundamental change in the overall pattern" since 2014. The number of mass events in 2015 is even slightly higher than that in 2014. "In 2016, the number of mass events in China has basically maintained the previous level." In addition, the "China Rule of Law Development Report NO.12 (2014)" issued by the Institute of Law of the Chinese Academy of Social Sciences shows that the number of mass events of more than 100 people has increased from 23 in 2007 to 163 in 2010, and even reached 209 in 2012. Start. In the first half of 2016 alone, there were 12 mass events of more than 1,000 people (Yu, 2018). The types and proportions of mass events can be described as shown in figure 1.
Figure 1   Types and Proportions of Mass Events

The survey found that more than half of the mass events were triggered by disputes between equal subjects, and the contradiction between the government and the people was second. This phenomenon has aroused the attention of many researchers, and the cause of mass events has become the top priority of research (Xin, 2015). From the perspective of sociology, the issue of interest is recognized as the most important cause of mass events. Hu Lianhe analyzes several theories of foreign mass events (Hu,

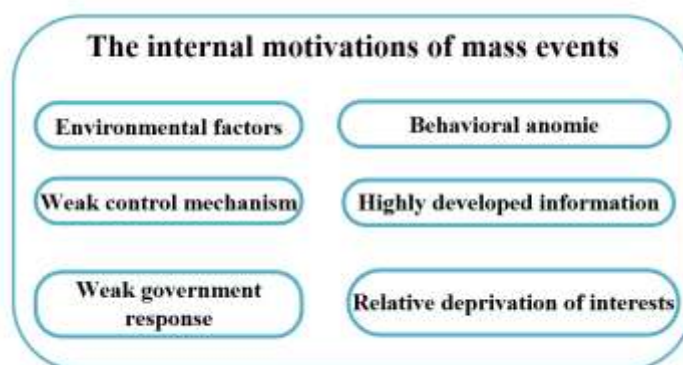
2017). At the same time, some scholars pointed out that there are other influencing factors besides the interests. Wu Fuguang and others believe that the lack of public reason has aggravated the structural contradictions of China's society and is an important cause of mass events (Wang Zili,et.al,2012). Lai Anting discovered through investigation that the spread of group emotions is an important factor in triggering mass events (Lai Anting, 2013). The 2010 China Social Development Report of Renmin University of China summarized the causes of the outbreak of mass events in China: weakened social control mechanisms, increased class conflicts, lagging government response mechanisms, and highly developed information dissemination. As shown in figure 2, the six factors of environmental factors, behavioral anomie, weak control mechanism, relative deprivation of interests, weak government response, and highly developed information are the internal motivations of mass events.


Figure 2   The 6 internal motivations of mass events

Regarding the governance of mass events, Wu Fuguang believes that the government should make public decisions from the requirements of public reason rather than from the rationality of the government (Wang Zili, 2012). The media should be a public platform for expressing and aggregating various interests. From the perspective of political science, Liu Chao proposed to establish and improve measures such as interest adjustment mechanism, social mobility mechanism, interest expression mechanism, diversified contradiction dispute resolution mechanism, petition mechanism, social catharsis mechanism, and social stability early warning mechanism (Liu Chao,2009). Many of the above reasons show us the possible conditions for the occurrence of mass events from rationalism. However, mass events are not only caused by unreasonable social factors, but also by the interaction and transformation of the psychology and behavior of individuals and groups. What psychology in a society ruled by law has prompted many people to choose to express their own interests through group action? What factors have prompted rational individuals to participate in group irrational behavior? Under what circumstances does individual behavior lead to rational or irrational group behavior? Understanding the law of group development from the perspective of social psychology and the psychological roots of individuals' excessive performance in irrational group behavior have become the breakthrough point for dealing with mass events.

Therefore, this paper aims to analyze the causes of this kind of irrational group psychology, hoping to avoid the irrational behavior of the group and maintain social stability.

2 Mass Events and Group Behavior

Group is composed of different individuals. The group behavior is based on the individual's psychological activities. The individual's psychology and behavior directly affect the group's state. First of all, we must explore the relationship between individual psychology and group psychology. Secondly, mass events disturb social order and threaten social stability. There must be some degree of irrational reasons.

2.1 Relationship between individual behavior and group behavior

Mass events are behaviors triggered by specific contradictions, which express material or spiritual interests, safeguards rights and interests, vents dissatisfaction, and directly affects social order and social stability. Mass events are external manifestations of group behavior, while group behavior is composed of countless individual behaviors, and individual behavior is the basis of group behavior. But in reality, individuals act according to their own cognition and rational judgment, while group behavior shows a

certain degree of unconscious blindness. Thus, group behavior is not a simple addition of most individual behaviors. In the process of integrating individuals into groups, individual psychology and behavior have undergone qualitative changes. Le Pen also pointed out that "individuals are mostly rational people in reality, but they become barbarians in the group - that is, an animal whose behavior is dominated by instinct. He is fierce, excitable, involuntary, and instinctive. He is willing to be impressed by his impassioned words and desperate behavior, and these words and actions cannot have any effect when the individual in the group is alone." (Gustave Le Bon, 1895）Similarly, it is not appropriate to speculate on the individual's psychology and behavior from the perspective of group behavior. Group behavior also can not reflect the psychology and behavior of all individuals. Whether individuals involved in mass events are rational, this requires re-judgment according to specific circumstances.

2.2 Irrational factors existing in mass events

In most cases, the psychology and behavior of individuals and groups are both rational and irrational. Not all mass events are caused by group irrational behavior. In reality, there are also planned and organized rational group action. Not all group irrational behavior will cause mass events, and only the behavior rising to the level of endangering social stability will constitute mass events. However, there must be a certain degree of irrational factors in almost all mass events. Social psychology holds that cognition, information and environment are the three major factors that determine individual behavior. If group members play their cognitive functions and fully understand the information provided by the internal and external environment to make certain behaviors, then members' behavior is the rational behavior within the social norms. On the contrary, when the rational judgment is lost due to the uncertainty of information and environment, the behavior based entirely on emotion, intuition, blind obedience and temporary impulse. So the behaviors are irrational. According to the theory of social infection, it occurs in the same physical space, but its members cannot be contacted by everyone in a large group. The cyclic reaction is very strong. Individual emotions can trigger others to produce the same emotions, while others' emotions in turn aggravate the original emotions of individuals. In this infection, emotional agitation is easy to break out. It is easy to cause irrational behavior of group. Once irrational emotions begin to spread in the group, they will spread to other individuals at a viral rate, which will trigger the turmoil of the entire group and cause mass events. Mass events are caused by interest disputes. Some irrational factors that are bound to exist. It is used as a means of giving vent to discontent, which has caused negative effects.

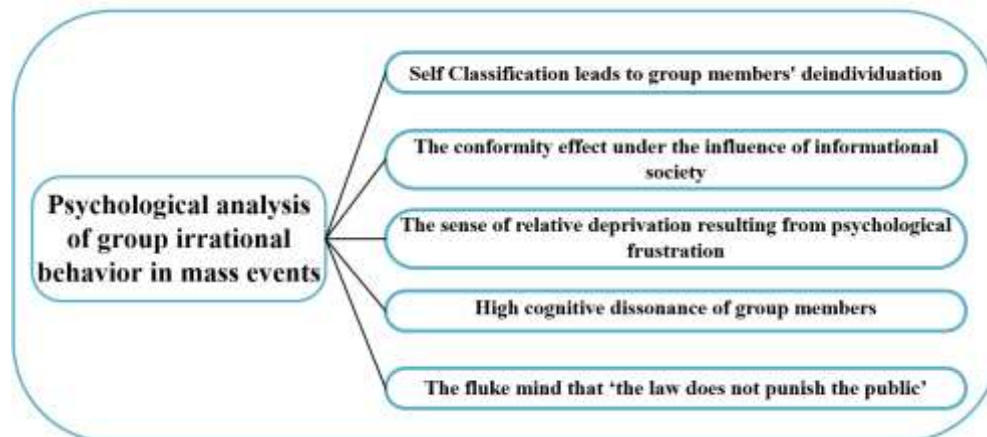
3 Psychological Analysis of Group irrational Behavior in Mass Events


Figure 3   Psychological Roots of Irrational Behavior

3.1 Self Classification leads to group members' deindividuation

The theory of Self Classification holds that when an individual's status in a group becomes more prominent, the individual regards himself as a model of the group rather than a single individual. The theory holds that individuals differentiate themselves from others according to certain characteristics and then classify them as internal and external groups.（Lai Anting, 2013）At this point, the members of the internal group actually become part of the individual, and the individual will consciously identify the values, attitudes and behaviors of the members of the group. Individuals also discover and accept

themselves in this way of self-classification and find a sense of belonging. When the internal group is subjected to external threats, their own interests are damaged or spiritual oppression, people will take the initiative to cater to members of the internal group and exclude members of the external group. Individuals lose their individuality and merge into groups. This process is called deindividuation. For example, in the process of demonstrating against the forces of foreign aggression, individuals classified themselves as members of the nation, and the concept of internal group members extended to the whole country. At this point, the internal contradictions disappear, and individuals shift their attention to the topics of collective concern. Group emotions are no longer dominated by rational individuals. With the continuous development of the situation, group emotions are expanding and irrational behavior is triggered.

3.2 The conformity effect under the influence of informational society

Conformity is a common psychological condition in mass events, and it is also a psychological impetus that cannot be neglected to cause group irrational behavior. American scholar Solomon Assy conducted a study of individual stress in groups in the early 1950s.It is found that individuals may have herd behavior in the face of group pressure, and the size of the group has a direct impact on the herd pressure. There is a functional relationship between them. When the majority of the members increase to more than three, the growth of the herd curve tends to be gentle.(Ji Naili, 2010)Informational social impact theory says that we conform because we believe that other people interpret a vague situation more correctly than we do, and that it helps us choose an appropriate way of behaving.(Social Psychology, 1999) Since the individual is unclear about what should be done in a situation that is overwhelming or unusual, then the behavior of the surrounding people becomes the source of their response to the situation, and they decide to act in a similar manner. Others are not willing to be laughed at because they are different or are excluded by group members. Individuals will think that the behavior of group expectations will not be ignored by others. Because "under the pressure of Group Consensus, individuals have an instinctive fear of deviating from the group, and lifting the conflict between themselves and the group can enhance the sense of security."(Mao Zhihong, et.al, 2013)In 1961, during the American Civil Rights Movement, militants trained people to fight violence in a negative way. Thousands of blacks, faced with repeated beatings, sticks, and floods, chose to persist in non-violent resistance. It can be seen that people in any situation, even when threatening their own lives, will make irrational herding behavior in an extreme and unexpected way.

3.3 The sense of relative deprivation resulting from psychological frustration

Merton believes that relative deprivation refers to the feeling of deprivation when people find themselves in a disadvantaged position by comparing their situation with a certain standard or a certain reference. This feeling produces negative emotions, such as anger, resentment or dissatisfaction. When the individual's group suffers from some kind of deprivation or threat, the members of the group will be angry and take irrational behavior under the influence of psychological frustrating pointed out that the actual process of group action consists of three stages: the emergence of dissatisfaction, the politicization of dissatisfaction and the violent actions against political goals.(Gao Chunya, 2014)First of all, group members are psychologically deprived of feelings due to certain events, which in turn leads to dissatisfaction. As the situation develops, this kind of emotion escalates and leads to psychological imbalance of group members. The government has become the appeals object of group action and hopes to eliminate this sense of relative deprivation. However, when an existing system cannot accommodate the regular interests of the group, some people will incite the entire group to make irrational behavior. For example, many land acquisition problems and mass events caused by demolition problems in recent years have followed such a law. The accumulated deprivation of individuals has prompted them to attract attention only through irrational group behaviors such as gathering people and sitting in demonstrations.

3.4 High cognitive dissonance of group members

Cognitive dissonance occurs when a person's behavior threatens his self-image and does not conform to a positive self-concept. Most people believe that they are rational individuals, but in some cases, people's ideas for maintaining their self-esteem are not necessarily rational, but are rationalized. People who are in a state of maladjustment are committed to convincing themselves that their actions are right, so that they tend to show irrationality and maladjustment. When an individual makes a decision and spends a lot of time and energy on the decision, the rational need for rationalization of these investments is stronger. When it is found that the development of the situation is mismatched with the individual's own cognition, it is emotionally unacceptable and then they would choose irrational coping behavior. In the Tianmen education incident in California in 1997,believers sacrificed a lot for

their beliefs, and eventually committed mass suicide because they couldn't see the so-called spacecraft.

3.5 The fluke mind that 'the law does not punish the public'

In group irrational events, the fluke mind has prompted some people to take the opportunity to mislead the public to vent their emotions or defend their own interests, so that the event continues to expand in an unusual direction. The fluke mind is the human instinct consciousness, which is reflected in the individual thinking activities, usually not enough to control people's behavior activities, but when a person's self-control ability is not strong, this subconsciousness is gestated and expanded, will trigger impulse. Members of irrational groups generally believe that "the law does not punish the public." When a group event occurs, the individual who has lost his sense of social responsibility will do whatever he wants to escape the legal responsibility. This provides an opportunity for individuals who take the opportunity to use their own means to gain profits for themselves.

4 Measures to Prevent Mass Events

4.1 Cultivate the crisis awareness of social members about mass events

Maintaining social order to ensure social stability is the responsibility of every social member. For various reasons，most mass events are not accidental. Reasons include either organized and premeditated maintenance of self-interest appeals, or the outbreak of social conflicts in daily life, or inciting emotions by people with ulterior motives. In the face of such mass events, members of society must first establish a correct attitude, hold a rational and tolerant mentality, curb ignorance and extreme emotion, promote civilization and cooperation, and fully recognize the important role of law. Only in this way, individuals will not be affected by the conformity psychology, the lucky psychology and cognitive dissonance in the face of crisis events, in order to maintain the right direction. Secondly, the crisis response ability of members of society is an important requirement to prevent irrational mass events. Individuals should pay attention to cultivating their ability to be acutely aware of the development of those events. And provide early warning to government departments or use their own resources at an appropriate time. Measures such as mitigating contradictions promptly prevent the expansion of the situation. In an appropriate time, by providing early warning to government departments, or using their own resources to temporarily ease conflicts and other measures can prevent the expansion of the situation in a timely manner.

4.2 Give full play to the power of the media, solve the problem of unsmooth information in time

It can be inferred from many mass events that a large part of group irrational behavior is due to the lack of the right to know. Once information is lost, people's cognitive judgments will be affected, and irrational behavior will follow. At the beginning of a mass incident, government agencies should promptly use the mass media such as television, online news, Weibo, WeChat to make detailed reports and actively dispel the rumoring addition, the network information dissemination exists one-sidedness and exaggeration, we should use authoritative media to report objectively and fairly. The handling process and results of the incidents should be timely announced and explained through the media, so as to enhance the credibility of government departments at all levels and stabilize the people's minds.

4.3 Government departments must establish an early warning and emergency response mechanism

Because irrational groups are extreme and impulsive, the government must not simply ignore or judge the psychology and behavior of such irrational groups, or require their irrational psychology and behavior to undergo rational qualitative changes, but should be more open and tolerant. Under the current situation, the government should standardize the law enforcement actions, and establish an early warning and emergency mechanism that can react to such irrational group behaviors immediately. Through the popularization of law education, efforts should be made to improve the people's awareness of the rule of law, so that they can understand and abide by the law, so as to stimulate the rational thinking of the whole society to achieve the effect of treating both the symptoms and the root causes and achieve the unity of legal effect and social effect.

5 Conclusion

This paper proposes the relevant measures to prevent irrational behavior by focusing on the five psychological root causes of irrational behaviors. It provides some basis and reference for social governance such as cultivating members of society to cope with the crisis awareness of mass events, exerting the power of the media, and establishing early warning and emergency response mechanisms for government departments.

Engineering Harmony Evaluation Based on System Dynamics

Wang Qiankun, Zuo Weiwei
School of Civil Engineering and Architecture, Wuhan University of Technology,
Wuhan, P.R. China, 430070
(E-mail: wangqk@whut.edu.cn, whutzuo@126.com)

Abstract: There are many factors influencing the engineering harmony. Harmonious engineering is not only to pursue the shortest duration or the best quality or the lowest cost, but to seek the harmony among schedule, quality and cost. This paper takes schedule, quality and cost as three major objectives of harmonious engineering management. Based on the method of system dynamics, the sub-models of quality, duration and cost coordination relationship are firstly constructed respectively, and then the structure equation of engineering harmony evaluation including cost overdraft factor, schedule delay factor and quality loss factor is established and analyzed by simulation.
Key words: Harmony; Quality; Duration; Cost; System dynamics

1 Introduction

The engineering construction has experienced the development process of "revering nature, conquering nature, and the harmonious coexistence of human and nature" (Yin ruiyu, 2008). The engineering construction cannot be separated from the harmonious development of human and nature. With the development of The Times, the harmonious engineering aiming at resource conservation, environmental protection and economic development is the goal pursued by enterprises and society. Lin maoguang put forward the basic framework of engineering construction harmonious management from 2014, and put forward the mechanism of human, matter and material on engineering construction harmonious management (Lin maoguang, wang qiankun, peng huatao, etc., 2014). The fundamental purpose of building a harmonious engineering is to keep human, matter and material in the most ideal state, so as to improve and optimize the economic and environmental benefits of the system continuously (wang yumei, 2018). The existing research mainly focuses on the pairwise comparison of duration, cost and quality in engineering construction management (expensive gold, 2015; Gao hanbing, ma zhiming, gu wenjie, et al., 2014).There is a lack of direct modeling and simulation of the relationship between the three to find the best harmony value.

2 Model hypotheses

There are many factors involved in the harmony engineering, which can be regarded as a complex system. The system constructed in this paper is designed to realize ideal engineering schedule, quality and cost, so as to achieve the harmonious engineering goal of technical goal, economic goal and environmental goal.

2.1 Mutual influence of engineering materials, labor force and capital

The realization of engineering cannot be achieved without the availability of resources, and the availability of resources depends on the four production factors of engineering materials, labor force, capital and equipment. As the use of equipment is small for the three relatively, this paper will not discuss it here (zhong yong, Chen zhigao, zhou zhong, 2016). The stock material is in positive feedback relation with the engineering schedule. The faster the stock material consumption, the faster the engineering schedule, and the more cash flow is needed to purchase materials. Stock material is sufficient, the engineering is adopted at any time, and there is no need to wait for procurement, the more likely the engineering schedule will be completed ahead of time. As for the negative feedback relationship between the labor force and the engineering schedule, the slower the schedule, the less the completed workload, the more the remaining workload, the more the work intensity or quantity of the labor force, and the more the cash flow is needed to realize the overtime wage or employment wage of the labor force. Based on this, the paper assumes that the worker's level of labor productivity and speed remain unchanged throughout the construction process.

2.2 Mutual influence of engineering schedule, quality and cost

Schedule, quality and cost are the most important factors in engineering management. Some scholars consider the three linear relations (Badu, Suresh), while others consider them as non-linear relations (Tareghian). When the engineering schedule falls behind the planned schedule, the schedule pressure will be generated. Generally, the working intensity of the workers will be increased to catch up

with the engineering schedule. However, the work intensity will make the workers feel tired, which will lead to the decline of quality, the rework of the engineering, and lags behind the schedule. This is a positive feedback system (liu Yang, lu mei, 2011). Based on this, the system assumes that the management staffs take measures to improve the work intensity of workers to catch up with the schedule. When the engineering quality is optimal, the engineering period is approximately the most likely duration. When the quality is worst, the period is approximately the shortest duration. When the quality is the best, the period is approximately the longest duration.

3 Model construction and simulation

The three core objectives of harmonious engineering management are quality, schedule and cost of engineering. As long as one of the three variables changes, the other two will also change. Under the same conditions, blindly accelerating the schedule will inevitably lead to unqualified quality and rework, and the cost will increase accordingly (Yang fang, 2012). The harmony engineering is not only to pursue the shortest duration or the optimal quality or the minimum cost, but to seek the harmony among schedule, quality and cost. Engineering has multiple processes, multiple schemes and multiple objectives, and the whole system is complex relatively. This paper assumes the construction of a harmonious engineering system based on multiple processes, one scheme, and multiple objectives. Besides, there are punishment of cost overexpenditure, delay and quality loss (Mrad, al-gahtani, Hulchafo, 2017). The total objective function is:

$$opt（Z）= minf（T,Q,C）\tag{1}$$

$$T = \sum_{j=1}^{n} t_j \qquad Q = \sum_{j=1}^{n} w_j q_j \qquad C = \sum_{j=1}^{n}（c_j + a_{1j}K + a_{2j}K + a_{3j}K）$$

In the above formula, "T" represents the total construction duration, "i" represents the mode of the engineering (i.e. the execution scheme), "m" represents the general mode type of construction, "j" represents the process of the engineering, and "n" represents the total process quantity. "t_j" represents the construction duration of the j process, "a_{1j}" represents the delay punishment of the backward schedule; "Q" represents the total quality level, "R_q" represents the required quality level, "W_j" represents the weight of the quality of the "j" process, and "q_j" represents the quality of the "j" process. Meet the requirements $q_j \geq R_q$."a_{2j}" represents daily penalties for deviation from required quality levels, "K" represents total delay time, "C" represents total cost, "c_j"represents the cost of the "j" process, "a_{3j}"represents cost penalty for exceeding deadline π ,"L" represents deadline of the engineering, $K \geq T - \pi$ and$T \leq L$，assuming that $a_{3j} = 2 * C/\pi$, Parameter constraints are as follows: $0 \leq j \leq$ n, $0 \leq W_j \leq 1$。

$$H = minf\{|\frac{T_p - T_s}{T_s} \quad \frac{Q_p - Q_s}{Q_s} \quad \frac{C_p - C_s}{C_s}|\}\tag{2}$$

"H" represents the degree of engineering harmony, which is the comparison between the actual situation and the standard situation of the plan. "T_p"represents the actual time, T_s represents the standard time, and Q, C means the same. The degree of harmony is the harmonious and stable state, and the state of the most reasonable cost, optimal quality and optimal schedule is sought.

3.1 Quality-cost model

According to the relationship between engineering quality and cost, the higher the quality requirement, the higher the cost. However, when the quality reaches a certain range, the quality needs to be improved again, and the cost will increase exponentially, which means that the improvement of the quality will require more expensive costs than before. Engineering cost includes quality assurance cost and quality loss cost, total quality cost is the sum of them. Through the research of scholars, it is found that the quality assurance cost increases with the rise of quality, and the quality loss cost decreases accordingly. The relationship between the two and the engineering quality level presents an exponential function relationship (zhang lianyin, luanyan, zou xuqing, 2013), while both the quality assurance cost and the quality loss cost are limited. In this case, the relationship between engineering quality and engineering cost is a positive feedback seeking behavior. The quality of engineering is not completely consistent. There are the highest and lowest standards for the overall quality level. In any case, the completion of works required is reasonable. Based on this, the following relationships exist:

$$Q = \sum_{j=1}^{n} w_j q_j \tag{3}$$

$$q_j = log\left(x_j * c_j + y_j\right) \qquad c_j = c_{1j} + c_{2j} = k_{1j}Q^{r_1} + k_{2j}Q^{r_2} \qquad (4)$$

$$x_j = \frac{e^{0.99} - e^{0.75}}{maxc_j - minc_j} \qquad y_j = e^{0.99} - a_j max\,C_j$$

"q_j" represents the quality level of the "j" process, "c_{1j}" represents quality assurance cost, "c_{2j}" represents quality loss cost, "k_1, k_2, r_1, r_2" represents constant(zhang lianying, 2013), Q ∈ [0.75,0.99], "j" represents process, "x_j, y_j" represents the constants corresponding to different processes, "c_j" represents the costs corresponding to different processes, "$min\,c_j$" represents minimum quality standard, "$max\,c_j$" represents highest quality standard（Mrad、Al-Gahtani、Hulchafo,2017）.

3.2 Duration-cost model

Too short or too long construction period will lead to increased engineering costs. There is always the possibility of rework. The probability of error increases the probability of rework. From the perspective of the relationship between duration and cost, no matter how to shorten or catch up the construction duration, it will promote the increase of cost (zhang lianyin, luanyan, zou xuqing, 2013), and it is believed that the direct cost and schedule are in a quadratic function relationship. The construction period is shortened, the management cost of management staff is reduced, and the engineering indirect cost and the engineering period become linear positive correlation. Based on this, the following functional relationship exists:

$$C（T) = Me^{-\mu T} \qquad (5)$$

In the above formula," M" represents the cost factor, "μ" represents constant, and$M > 0, \ \mu > 0$.

3.3 Quality-duration model

The improved of quality level is limited; it is hard to be perfect. If we blindly pursue the schedule, quality problems may arise, resulting in rework phenomenon, which will reduce the economic benefits of the construction enterprise. In order to guarantee the quality, the careful and careful work will lead to the delay, and the cost will increase accordingly. Moreover, there is deviation between the actual quality and the required quality, with the highest quality level and the lowest quality level. This paper assumes that the level change range is [0.75, 0.99] (Mrad, al-gahtani, Hulchafo, 2017).

$$Q = \sum_{j=1}^{n} w_j q_j \qquad q_j = Ne^{-\lambda t}, \ t_{jmin} \le t \le t_{jmax} \qquad (6)$$

In the above formula," N" represents the quality factor,$0.75 \le N \le 0.99$, "λ" represents the constant of the concave function,$\lambda > 0$.

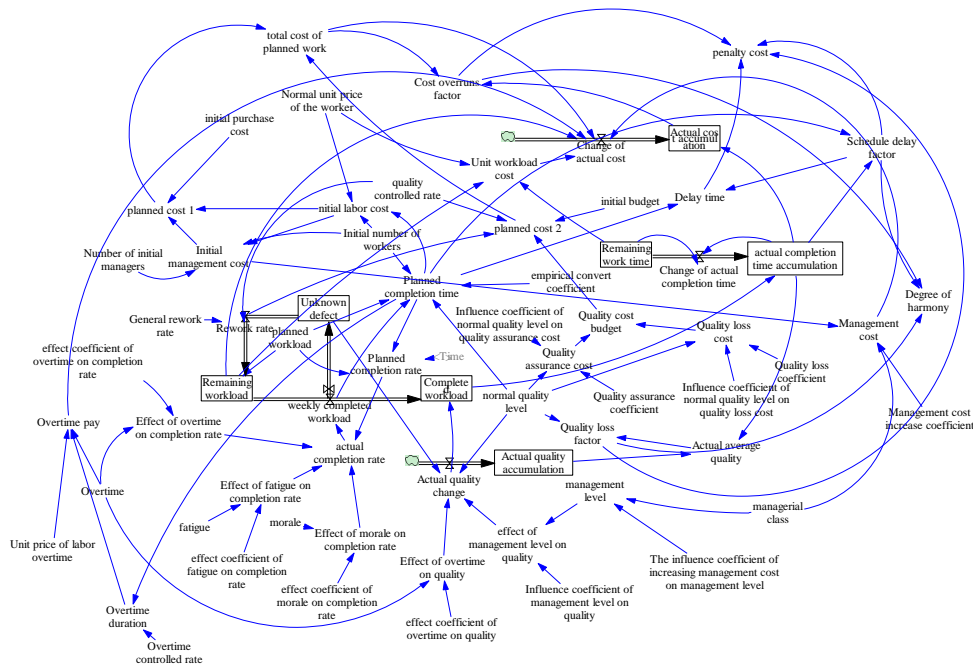
3.4 Structure of system flowchart


Figure 1   System Flowchart

3.5 Fundamental structural equation

Remaining workload = planned workload - weekly completed workload + planned workload * rework rate

Weekly completed workload =INTEG (- actual completion rate, weekly completed workload)

Planned workload =100, dimensionless

Rework rate = general rework rate/quality controlled rate (zhang shan cong, dong xiaohuan, 2013)

General rework rate =10%, dimensionless

Quality controlled rate =100%, dimensionless

Actual completion rate = planned completion rate * (1- effect of overtime on completion rate) * (1- effect of morale on completion rate) * (1- effect of fatigue on completion rate)

Effect of fatigue on completion rate = fatigue * effect coefficient of fatigue on completion rate

Effect of morale on completion rate = morale * effect coefficient of morale on completion rate (or using table function)

Effect of overtime on completion rate = overtime * effect coefficient of overtime on completion rate

Effect of overtime on fatigue = overtime * effect coefficient of overtime on fatigue

Effect of overtime on morale = overtime * effect coefficient of overtime on morale

Effect of overtime on quality = overtime * effect coefficient of overtime on quality

Overtime, fatigue, morale ={0,1}, means yes and no.

Overtime pay = overtime * overtime hours * unit price of labor overtime

Unit price of labor overtime =500 yuan/day

Overtime duration = overtime controlled rate * planned completion time

Overtime controlled rate =25%, dimensionless

Planned completion time = weekly completed workload /(empirical convert coefficient * normal quality level * planned workload/initial number of workers)

Initial number of workers =50

Normal quality level = {[0.75, 0.99]}

Planned cost = planned cost 1+ planned cost 2

Planned cost 1= initial purchase cost + initial labor cost + initial management cost

planned cost 2=(initial budget + quality controlled rate * quality cost budget)*(1+ rework rate)

Quality cost budget = quality assurance cost + quality loss cost

Quality assurance cost = quality assurance coefficient* normal quality level $^{\text{Effect coefficient of normal quality level on quality assurance cost}}$

Quality loss cost = quality loss coefficient* normal quality level $^{\text{Effect coefficient of normal quality level on quality loss cost}}$

Initial management cost = initial labor cost /{ number of initial managers /(number of initial managers + number of initial workers)}

Number of initial managers = 2

Initial labor cost = normal unit price of the worker * number of initial workers * planned completion time

Normal unit price of the worker =300 yuan/day

Management cost = initial management cost * managerial class * (1+ management cost increase coefficient)

Managerial class ={0.3,0.5,0.8}, the higher the value, the higher the management level, the better the management level.

Management cost increase coefficient ={0.3,0.5,0.8}, respectively representing the increase coefficient of management cost corresponding to the management level.

Schedule pressure = table function (remaining workload/weekly completion workload)

Planned completion rate =10 pieces/day

Unknown defect =INTEG (0, rework rate), dimensionless

Material inventory on construction site =INTEG (material purchase rate - material consumption rate, initial inventory on construction site)

In the formula, there is pipeline DELAY and DELAY FIXED (material procurement rate, delay time, initial value) when material procurement arrives at the construction site, and material consumption rate = actual completion rate.

The managers will adjust the schedule according to the remaining construction period. Planned completion rate = IF THEN ELSE (planned completion time -Time ≤ 0, planned workload, planned workload/(planned completion Time -Time))

Completed workload =INTEG (100, actual quality change + weekly completed workload) piece

Other purchase costs = 500,000 yuan

Actual quality change = normal quality level *(1- unknown defect)*(1- effect of overtime on quality)*(1+ effect of management level on quality)

Actual quality accumulation =INTEG (actual quality change, actual quality accumulation)

Actual average quality = actual quality accumulation/actual completion time accumulation

Remaining work time =INTEG (- change of actual completion time, remaining work time)

Change of actual completion time =(actual completion time accumulation - remaining work time)/ actual completion time accumulation

Weekly completed workload =INTEG (- actual completion rate, weekly completed workload)

Unit workload cost = remaining workload/remaining working hours * normal unit price of the worker

Change of actual cost = total cost of planned work- remaining workload * unit workload cost + overtime cost + management cost

Actual cost accumulation =INTEG (+ change in actual cost * actual completion time accumulation, 1000000)

4 Results of Simulation

Cost overruns factor =ABS (total cost of planned work - Actual cost accumulation)/ total cost of planned work

Schedule delay factor =ABS (completion time of planned project - actual completion time accumulation)/ completion time of planned project

Quality loss factor =ABS (normal quality level - actual average quality)/ normal quality level

Degree of harmony = cost overruns factor * schedule delay factor * quality loss factor
Degree of harmony

Figure 2   Simulation Results of Harmony Degree

In the initial state, the engineering harmony changes in stages. From 0 to 11 months, it shows a linear growth trend, and the engineering harmony increases from 0 to 19.6513. In the period of 11-22 months, it then shows a downward trend, falling to 0.0674499. In the period of 23-98 months, it shows an exponential growth trend, and the degree of harmony is once increased to 104.659. In the last two months, the degree of harmony drops to 68.7107. The lower the harmony value we pursue, the better. It indicates that cost overruns, schedule delays, quality losses and other problems will be less. This point is in the 22nd month, the harmony value is 0.0674499.

5 Conclusion

Engineering has multiple processes, multiple schemes and multiple objectives, and the whole system is complex relatively. This paper assumes the construction of a harmonious engineering system based on multiple processes, one scheme, and multiple objectives. And at the same time, there are punishment of cost overexpenditure, schedule delay and quality loss. The study found that, in the initial state, the engineering harmony changes in stages. From 0 to 11 months, it shows a linear growth trend. In the period of 11-22 months, it then shows a downward trend. In the period of 23-98 months, it shows

an exponential growth trend. In the last two months, the degree of harmony drops to 68.7107. The lower the harmony value we pursue, the better. It indicates that cost overruns, schedule delays, quality losses and other problems will be less. This point is in the 22nd month, the harmony value is 0.0674499.

The harmonious engineering construction is different from the general engineering construction. The engineering itself is to achieve the balanced optimization of quality, duration and cost, rather than the maximization of a single goal or the comparative optimization of two goals. Therefore, a single objective function of quality, duration and cost should not be constructed, and multiple multi-objective functions must be built. That is to say, the harmony of engineering construction is not to seek the optimal solution of single objective with the highest quality, the shortest construction period and the lowest cost, or comprehensive optimal solution of them, but to seek a satisfactory solution of quality, construction period and cost coordination under the consideration of economic, political and environmental factors. Thus it achieves the technical goal, the economic goal, and the environment goal of harmonious engineering system.

A Critical Review of Financial Distress and Business Failure Prediction Models

Peng Huiran[1], Hu Xinyue [2]
1 Master in Economics, University of Wisconsin-Madison
2 Warwick Business School, UK
(Email: phrsummer123@hotmail.com, 1979980317@qq.com)

Abstract: This report, based on past academic literature, aims to provide analyses on the concept of financial distress and to assess the Altman's Z-score model by comparing it to other financial distress prediction models. To achieve this end, the report introduces in section 2 the theory and the definition of financial distress, as well as presenting an example of the shipping industry in China. Section 3 gives a literature review of preceding financial distress prediction methods. In section 4, this report discusses advantages and limitations of the Altman's Z-score model. The final section offers conclusions and critically evaluates the following view: "Altman's Z-score approach provides us with all we need to know in this area, therefore alternative approaches are surplus to requirements."
Key words: Financial distress; Altman's Z-score model

1 Introduction

Financial distress theory has become one of the forefront and hot issues of capital structure theory, especially in recent decades.

In Beaver's (1968) study, he identified 79 firms as in financial distress, including 59 bankruptcy firms. Carmichael (1972) following Beaver's study, defined the financial distress as to fulfil their obligations for the company blocked, with specific performances such as lack of liquidity, equity, debt default or lack of funds and other four forms. And according to Pastena and Ruland (1986), financial distress is a condition where a firm is unable to pay debts when due, and the market value of its assets is less than total liabilities. The firm usually continues to trade under court protection.

Kahl (2002) observed that financial distress had long-term impact on the capital structure, investment policies, and performances of many firms even after they emerged from debt restructurings. While preceding studies have also shown the same tendency. Campa and Camacho-Miñano(2015) indicated that firms' negative operating income existed for 5 years after their bankruptcy protections. And Gilson (2012) showed that firms continued to be highly levered, even after suffering from financial distress.

Financial distress can be very costly(Guariglia et al., 2016)(Baghai et al., 2016). Gupta et al.(2014) clearly indicated that the cost of financial distress could be separated as direct and indirect. This is also the most used method. Direct costs include bankruptcy fees and legal fees. Indirect costs, according to Erel, Myers and Read (2015), can be caused by underinvestment. And this underinvestment can also lead to the loss of good employees and the product-market issues.

However, Adelino and Dinc(2014) and Farooq et al.(2012) used ex ante cost and ex post cost to evaluate the total cost of financial distress. Ex ante cost means the cost before firms go bankruptcy, such as the managerial cost and the risk cost. Ex post cost means the cost after firms go bankruptcy, such as the transaction cost during the process.

2 The Literature Review of Bankruptcy Prediction Models

Beaver et al. (2016) used financial information utilized univariate techniques to predict financial distress. He computed a financial ratio to separate failed from non-failed companies, based on a historically derived benchmark for that ratio. He also indicated that the ratio of cash flows to total liabilities proved to be the most efficient.

Altman (1968) first used multiple discriminant analysis, also known as MDA. This method is able to deal with combinations of two or more variables, and has largely increased the prediction accuracy. In 1977, Altman, Haldeman and Narayanan have brought ZETA model to people's eyes. The model is specified as: $Z = 1.2A+1.4B+3.3C+0.6D+1.0E$, where Z means Score, A means Working Capital/Total Assets, B means Retained Earnings/Total Assets, C means Earnings Before Interest and Tax/Total Assets, D means Market Value of Equity/Total Liabilities, E means Sales/Total Assets.

Meyer and Pifer (1970) applied the least square method to predict financial distress, mainly bank

failures however. They ran the regression analysis and discovered that one of those variables had shown a high level of goodness of fit, with R-Square equalled to 0.70.

Several more recent studies conducted by Jabeur(2017), Antunes et al.(2018), Alessi and Detken(2011), Caggiano et al.(2014), have all used probit and logit techniques. These approaches are widely known as conditional probability models.

Shumway (2001) has brought a simple hazard model in the paper "Forecasting bankruptcy more accurately: A simple hazard model". This approach uses both market-driven and accounting variables to identify firms in financial distress. It also adjusts to risk in different periods and allows for time-varying correlation variables.

3 Reasons for Financial Distress

Agbasonu and Osuagwu(2015) has proposed 8 reasons for financial distress, using theoretical analysis and case studies. These 8 reasons are: poor firm management, insufficient information, no proper response measures taken according to changes in the operating environment, restricting firm to react to environmental change, excessive business operation, large projects' development, business risk, and highly levered.

According to Chen et al.(2013), a firm's profitability depends not only on its managerial efficiency and its business condition, but also on the outside environment. If the economic does not go well or the industry of this firm underperforms, the level of competition will go up. In China, for instance, the change of policy will significantly influence the market, due to its incomplete market regulations. Therefore, some firms may face more risks of being financially distressed.

4 Example– the Shipping Industry in China

As an important foundation and service sector of China's economy, the shipping industry contributes greatly to China's foreign trade development. In recent years, however, following the slowdown of global economy, as well as the international shipping market recession and severe overcapacity, China's shipping industry has met a sharp deterioration. In the year of 2012, the public annual report showed that over 80% of 12 listed shipping companies suffered a huge loss and fell into severe financial distress. This situation not only decreases these companies' share price, but also weakens the faith of both investors and creditors. (Liang, 2014)

Liang (2014) has concluded three evidences on the shipping industry's financial difficulties: Increasing debts, decreasing debt-paying abilities, and less profit.

According to the table below, the total liabilities of China's shipping industry have increased enormously during this period. The long-term debts have increased 199% from the year 2008 to the year 2013. While on the contrary, the equity capital has experienced a huge decrease, from 611.25 to 399.15 (￥100 million). Hence, Liang (2014) suggested that the shipping industry in China raised funds mainly by issuing debts.

Table 1   Balance Sheet of the Shipping Industry in China

2008-2013 Balance sheet of the shipping industry in China (￥ 100 million) (resource: Liang 2014)

	2008	2009	2010	2011	2012	2013
Liquid Assets	440.12	551.97	610.25	638.86	634.5	715.88
Fixed Assets	865.44	956.74	1035.63	1092.02	1178.68	1185.97
Total Assets	1167.63	1386.2	1508.68	1574.37	1652.28	1721.95
Short-term Liabilities	239.3	270.68	284.03	473.16	399.05	475.35
Long-term Debts	2045.86	4097.65	3758.59	3315	5301.76	6119.39
Total Liabilities	556.38	852.27	886.48	1072.66	1235.3	1322.8
Equity Capital	611.25	533.93	622.2	501.71	416.98	399.15

However, this empirical approach has several limitations: It only observes the shipping industry in China. Thus, this result may not suit shipping industries in other countries. The result is regional limited; Liang (2014) has not indicated these listed companies' credit ratings; These statistics used are not up-to-date anymore. From our observation (Finance China.com, 23 Mar 2016), the financial situation of the shipping industry in China has experienced the worst year in 2014, and then has become slightly better.

5 Assessing Altman's Z-score Model

This section mainly introduces Altman's Z-score model in details, and discusses its achievements as well as limitations. Then it comes to the comparison between various bankruptcy prediction models, such as ZETA, Smaranda's(2014) application of Ohlson's conditional probability model, and the simple hazard model. At the end of this section, there is a summary including some criticisms of traditional accounting-ratio-based measures.

Basically, the multivariate discriminant analysis suggested by Altman (1968) classifies a firm into one of two groups: failed firms and non-failed firms, using a statistic Z score, which is a weighted combination of ratios. If Z score is bigger than zero, then the firm is healthy and not distressed; if Z score is smaller than zero, then the firm is classified as distressed. In United States business environment, Altman (1968) predicted 72% of the firms' financial distress with two years prior to their happening.

Although this approach is widely used: over a hundred studies have applied multivariate discriminant analysis to the prediction of business failure (Keasey and Watson, 1991), this does not necessarily equal to a high level of predictive accuracy.

According to Keasey and Watson (1991), there is a major disadvantage in Altman's Z-score model. That is: the multivariate discriminant analysis is not able to determine the significance of individual variables, for this analysis' coefficients can take on any value as long as the ratios between the coefficients of the variables are held.

The ZETA model (Altman et al, 1977) is an updated new version of z-score model (Altman, 1968). In ZETA model, two more variables are added in order to give a better prediction of bankruptcy firms. Altman himself has implied in 2000 that the ZETA model showed more accuracy in predicting firms' failure.

Conditional probability models are less demanding compared to multivariate discriminant models. Because the probit and logit techniques apply cumulative probability distributions and do not demand the independent variables to be multivariate normal (Keasey and Watson, 1991). This method can also determine the significance of individual variables, while not having the same demanding assumptions as multivariate discriminant analysis.

Shumway (2001) developed a hazard model for predicting firms' bankruptcy. This method is theoretically superior to the traditional accounting based models used previously for it is said to have corrected for period at risk and allowed for time-varying correlation variables. At the same time, this hazard model is quite simple to perform.

Agrawal and Maheshwari(2016), Matús(2016) and Andrikopoulos and Khorasgani(2018), Lee et al.(2015), Gupta et al.(2015) have outlined some criticisms towards the traditional accounting based measures. The first one is its historical nature: accounting based models present only past performance of companies. Secondly, accounting based models are built on sample analysis, which indicates that such models are very likely to be sample specific. Thirdly, management can easily manipulate accounting statistics. In addition, there could be various accounting standards.

To sum up, Altman's Z-score approach does have great many advantages. However this approach is definitely not a perfect one and needs to be continually amended.

6 Conclusion

This report focuses on the interpretation of financial distress and provides comparisons between various bankruptcy prediction models. It firstly discusses the concept of financial distress, based on many academic literatures. Then it uses an empirical approach, analysing the shipping industry in China. After given an overview of financial distress prediction models, this report continues to study the uses and limitations of Altman's Z-score model.

Finally, this report gives following conclusions: A). Financial distress has long-term impact on the capital structure, investment policies, and performance of many firms. B). Financial distress is never costless. C). Altman's Z-score approach cannot provide us all we need to know in this area, every model has its limitations.

(E-mail: 770869871@qq.com, 312862507@qq.com)

Abstract: Enterprises will encounter various kinds of risks in their daily production and management activities. Developing and strengthening risk management has become an indispensable work to maintain the existence and development of enterprises and is also an important content of modern enterprise management. This paper explains Enterprise Risk Management in details from four different perspectives. This paper analyzes the definition of Enterprise Risk Management, some factors influencing ERM, the ERM process and value at ERM. It comes to the conclusion that ERM makes great contribution to the development of companies and it can be improved through continuous effort and attention. This paper is beneficial for companies which needs more attention on ERM.

Key words: Enterprise Risk Management; Factors influencing ERM; Process of ERM; Significance of ERM

1 Introduction

Because of the economic crisis, many executives now realize that single risk can only be taken serious in the interaction with other risks. Risk is no longer considered isolated, but is identified, analyzed and controlled within the framework of all interaction risks (Passenheiem, 2013). Recent research has proved that almost all companies are looking at these risks in isolation. In the past few years, many subsidiaries have developed independent subsystems, such as legal requirements for managing risks. These companies focus on single risk, such as the Ministry of finance or compliance. The dependence between risks is often unnoticed.

This paper shows some information about risk management and enterprise risk management in detail. At first, this paper explains the main definition of risk management and enterprise risk management. It is not only about the definition of those two, but also about some specific relevant information, such as processing method etc. Then, it focuses on some factors which would make an impact on enterprise risk management.The fourth part shows the process of enterprise risk management. In short, the process includes risk identification, risk analysis, risk response and risk controlling. The final part is the significance of enterprise risk management to enterprises. In other words, it analyzes the reasons of enterprise risk management and how it could add value to the firm. The paper analyzes the significance of Enterprise Risk Management (ERM) from a comprehensive and detailed perspective.

2 Definition of Enterprise Risk Management

The structure of corporate risk management and the model and method of risk management based on established, technical and statistical experience do not always take into account the constant changes in market environment and the structure of the company. What usually lacks is the logical alignment between risk management and strategic business objectives. (William, 2015)

The challenge for the company is to integrate its built subsystems to develop a dynamic, integrated, company-wide risk management system. To establish a risk management function, administrators should not only position themselves in the company's goals, but also position themselves in strategy and culture. The company hopes that the objectives achieved through its risk management strategy must be compatible with the overall business objectives. At the same time, lessons learned from risk management can also lead to the adaptation of corporate goals and corporate strategies.

Finally, enterprises must look at the whole risk area they are in. In addition to classic risks, it can be strategic, operational and financial, or concerned with the legal environment, and the so-called emerging risks must also be taken into account. The emerging risk is global risk, which can be predicted only by climate change, political instability or energy price fluctuations. (Best, 2006)

The overall risk management is to carry on the comprehensive risk management to each link and process of the enterprise production and sale according to the enterprise management strategic goal, to cultivate the good risk management culture of the enterprise, and through the establishment of the comprehensive risk management system to achieve the overall goal of enterprise risk management.

Through the research and analysis of many scholars and experts, it is concluded that there are some

root causes of the current internal control of enterprises, such as the insufficient risk management of enterprises, which often limits the internal control of enterprises. Now people begin to pay more and more attention to the effective combination of internal control and risk management, strengthen risk management on the framework of internal control of enterprises, enhance internal control, and promote its identification and judgment of its own business environment and risk factors. (Gao, 2018) It would help enterprises keep up with the pace of market development, conducive to strengthening enterprise management, improve the strength of enterprises.

In the current theoretical research, there is no consensus on the interaction between risk management and internal control. Among the more mainstream views, the first is the framework theory of the United States, which holds that the latter includes the former, while the view of the Canadian scholars is that the former includes the latter, which gives rise to a third understanding. There is no relationship between the two. In the current research city, the first case is that internal control contains risk management.

3 The Framework of ERM

First is the internal environment. Whether the internal environment is good or not has an important impact on the future development of the enterprise. The internal environment is the important basis of other risk factors and provides the structure and rules for other elements. Whether the internal environment is good or not directly affects the construction and implementation of the enterprise risk management system, and directly affects the implementation of the enterprise risk management framework. (Zhou, 2018) Therefore, to strengthen the enterprise risk management, the first step is to strengthen the enterprise internal environment construction. The internal environment includes the knowledge system of risk theory, such as risk management philosophy, risk preference, internal moral integrity, board of directors' trustworthiness, moral value, human resource policy and assessment standard, competence and so on.

The goal setting refers to the enterprise management personnel, based on the current management objectives, to formulate and improve the strategic objectives of the enterprise, to clarify the related objectives, to strengthen the responsibility decomposition, and to implement to the people. Other related objectives mentioned again refer to three objectives that do not include the strategic objectives of the enterprise. The determination of strategic objectives is the most important part of enterprise risk management.

In the process of enterprise management, the enterprise managers should further clarify the uncertain factors in the process of implementing the strategy, and the factors that have adverse effects on the development of enterprises are called risks, and managers should respond to them in a timely manner. We call it an opportunity to promote the development of enterprises and reduce the possibility of risk. We should clearly distinguish risk from opportunity, so as to carry out relevant activities, reduce risks and seize opportunities.

Based on the analysis of the possible risks and adverse effects in the future development of enterprises, the management of enterprises is formulated and perfected. Before the risk assessment, we should fully integrate the strategic objectives of the enterprise. First of all, we should evaluate the existing risks, formulate reasonable measures to deal with the risks, and strengthen the measures to deal with the inherent risks. Secondly, the residual risk of the enterprise is evaluated.

After the enterprise risk assessment is completed, as the managers of the enterprise, it is necessary to formulate reasonable measures to deal with the risks. The ERM framework puts forward the following four types of countermeasures: risk avoidance, reduction, sharing and bearing. Enterprise managers should effectively integrate cost expenditure and risk tolerance, give full consideration to the dispersion of risk and the impact of various coping schemes, and find the best risk response plan to be implemented through comparison. Effective risk management requires managers to fix the possibility and impact of risk within the scope of SCR.

In the whole process of risk management, the establishment and adjustment of the activities, so that the real implementation of risk response measures. Risk management is accompanied by various links, levels and functional departments of enterprise production and management. It mainly includes two parts: to determine the policy and the degree of policy influence. Activities include approval, authorization, validation, reconciliation, performance audit, asset safety, and segregation of duties.

The process of enterprise production and operation is full of a lot of information, financial management information and enterprise management information is particularly important, is an

important part of enterprise production and management activities; In the early stage of information processing, responsibility and other important issues occupy a very important position. Information is the main content and object of communication, and communication is an important way to ensure the steady transmission of information. The research shows that the timeliness and effectiveness of communication are more conducive to the management right of enterprise managers and the smooth realization of enterprise management goals. Therefore, it is necessary to strengthen the information identification and processing, realize the effective communication of relevant departments, clarify the responsibility and implement the responsibility to the people.

The process of managing multiple components of risk and sustainability of risk management level. Risk monitoring prior, in the event, after the information has changed at any stage, monitoring information, reasonable adjustment. Monitoring methods are mainly divided into two categories: first, continuous monitoring. In the process of implementation, continuous monitoring is carried out to deal with all kinds of risks quickly to ensure the healthy operation of the enterprise; the second individual evaluation. Management decisions have a significant impact on frequency. In the process of enterprise decision, the following factors should be synthesized: the degree, nature and related risks of the internal and external environment change, the ability of risk execution and reaction, the strengthening of staff experience ability control, and the conclusion of continuous monitoring. (Li, 2017)

4 The Relationship between Enterprise Internal Control and ERM

Internal control and risk management are consistent to a certain extent. This is because both internal control and risk management play a positive role in the production and management of enterprises, and they run through the daily management process of enterprises, which is helpful for enterprises to realize the strategic goal planning smoothly. Risk management can prevent risk, detect risk, assess the loss that risk may bring to enterprise and effectively control risk. Internal control is the risk management adopted by enterprise, and its basis is risk. The greater the risk, the more internal controls need to be put in place. (Gong, 2018)

There are three views on the relationship, one is that risk management includes internal control, the other is that internal control includes risk management, and the other is that internal control is equal to risk management. At present, what has been unanimously recognized by the academic community is the former, that is, risk management includes internal control, and in addition to the goal of including internal control, it also expands the scope of the overall framework. To stand on the enterprise strategic development level to analyze the problem, and to solve the enterprise in the management process of many drawbacks, in the enterprise risk management involved in all aspects can play a greater role, and the internal control is mainly in accounting control, Role of audit activities, etc.. (Zhao, 2013)

5 The Factors Influencing ERM

One of the main factors which would influence inspection is that the existence of chief risk officer is positively related to the implementation of ERM (Mark et al., 2015). People will expect that having CRO will make the company more inclined to implement ERM because of its professional knowledge and possible CRO fit in the organizational structure. In addition to having CRO, researchers believe that the higher proportion of independent board members may lead to a higher likelihood of ERM implementation. Researchers put forward this hypothesis from the research done by Kleffner (2003), which shows that Canada Company's adoption of ERM is achieved through the encouragement of the board of directors.

The board of directors plays an important role in affecting the implementation of ERM, and management is the driving force of ERM implementation within the company. Without the support and guidance of management, ERM will not succeed in the organization. The study (Kleffner ,2003) examined the explicit requirements of chief executive officer or chief financial officer on internal audit participation in ERM. This has questioned the relevance of external auditors and its impact on the implementation of ERM. The researchers studied the relationship between the existence of the Four Auditors and the ERM deployment stage of the enterprises. Researchers believe that the four auditors are more inclined to risk management because of the explicit requirements of industry regulators and leaders. The study also examined the size of the organization and the implementation and phase of ERM within the company. It is expected that the size of the company is related to the four audits, two of which can work together to promote ERM.

The ability to cause economic fluctuations, such as the banking industry, is further found in the

implementation of ERM because of the inherent risks that shareholders, auditors and regulators experience after a variety of corporate scandals. With the development of the industry, the ability to manage risks must evolve along with the understanding of ERM managers in enterprises.

6 The Process of ERM

The purpose of monitoring all risks is to increase the value of every activity within the company. The enterprise risk management process mainly consists of target setting, risk identification and analysis, risk assessment measures, risk response, control activities to risk response, information and communication and good operation of monitoring and ensuring risk prevention.

Risk identification is the premise of all the following steps in the process. Risk identification should be done as a continuous process. If it is regarded as a one-off event, the whole company will be faced with the risk of emerging problems. The process begins with determining the start-up stage of the first risk. Resource allocation, scheduling and budgetary reserve plans at the planning stage should also be recorded.

All in the initial stages of risk identification, risks must be managed, until each risk was closed or terminated. And along with the development of the company, the changes of the company's external environment and internal environment will arouse new risks. The possibility of increased risk or risk into reality, the risk management team should respond to its managers and executives must consider the problem and develop strategies to deal with it. All the rezoning of action means change, which became the basis for the budget schedule and resource planning.

7 The Significance of ERM to Enterprises

Companies that maximize profits should consider implementing an ERM plan, only when it increases expected shareholder wealth. Although the individual advantages of different risk management activities are obvious, the traditional "silos" risk management methods are inadequate. Lack of coordination among different risk management departments will lead to inefficiency in managing each risk level in a separate silo. By integrating decisions of all risk categories, enterprises can avoid duplication of risk management expenditure by using natural hedging. Companies engaged in ERM can better understand the total risks inherent in different business activities. This provides them with a more objective basis for resource allocation, thereby improving capital efficiency and return on equity. Organizations with a wide range of investment opportunities may benefit from choosing a more precise risk adjusted ratio than traditional risk management methods.

Although individual risk management activities can reduce the volatility of earnings by reducing the probability of catastrophic loss, there is a potential interdependence between the cross activity risks that may be ignored in the traditional risk management model. ERM provides a structure that integrates all risk management activities into an integrated framework that helps identify this interdependence. Therefore, although individual risk management activities can reduce the volatility of income from specific sources, the ERM strategy reduces volatility by preventing risk aggregation between different sources. Another source of value for the ERM program is the improved information on the company's risk profile. Outsiders are more likely to assess the company's financial position and risk in terms of financial risks. ERM enables these opaque companies to better inform of their risk profile and signal their commitment to risk management. By improving risk management disclosure, ERM may reduce the expected cost of regulatory review and external capital. (Cui, 2016)

In addition, for insurance companies, the major rating agencies have placed the focus of risk management in a higher range, especially ERM as part of their financial review. This may provide additional incentives for the insurance company to consider the ERM project, and also imply the potential value implication of the ERM project of the insurance company. In October 2005, Standard & Poor's announced that with the emergence of ERM, risk management will become an independent main category of its analysis. In February 2006, A.M. Best released a special report describing its increasing concern for ERM in the rating process.

8 The Specific Suggestions to Enterprises based on ERM

First of all, the company should perfect the internal risk management system, combine the development goal and development strategy, construct and perfect the risk system, know the standard of the risk management work, and give the concrete risk management mechanism. The risk management of the company mainly combines the risk management direction and the idea of risk management. Based

on this, the strategic conception and goal that accord with the development of the company are worked out, which is the premise of the construction of the risk management system. The construction of enterprise comprehensive risk management system involves more complex theory, and also related to the work of various departments within the enterprise, so the company should build a multi-angle and three-dimensional management plan. In establishing a risk management system that conforms to its own characteristics, the company applies the eight elements of risk management, risk identification, risk analysis, and risk assessment. Risk management system should be set up in four links, and risk management system should be re-established and improved, and the system should be set up around these four basic links.

To create a good enterprise culture atmosphere is helpful to promote the enthusiasm of employees and create the atmosphere of risk management culture, then to improve the level of risk management within the enterprise, to ensure that the enterprise risk control goal to meet the standards. In the process of cultural construction and strengthening the risk control mechanism of the enterprise, it is also necessary to carry out the construction in this respect, which is regarded as the key goal of the development of the company. In the eight elements of risk management, it is pointed out that the quality of internal environment directly affects the normal operation of the company. It is the cornerstone of the company culture to improve the skills of the employees on the basis. Modern enterprises should not only strengthen their business, but also strengthen their corporate culture. The culture is inherited, and the employees of the company are highly qualified talents. Working in this kind of good and upward cultural atmosphere can stimulate the enthusiasm of employees and improve work efficiency, which is of positive significance to the construction of risk control mechanism framework of enterprises. The enterprise carries out many kinds of education and training to the employees to understand the culture of the risk control mechanism of the company. While creating a good corporate culture environment, management and middle-level cadres should play a leading role. At the same time, the core staff of various departments should take the initiative to respond positively to the call, give play to the backbone role, and form good professional integrity. The internal and external business of the company is carried out under the operation of legal compliance. In addition, we should establish the system of prevention and control in advance, predict beforehand, control in the middle, and strengthen the management of all aspects of risk after the event.

Messaging is the form of communication, learning, use and advice across multiple departments within a company. Good message delivery enables the company to keep track of the business situation and to prevent and defend against internal emergencies. Therefore, the establishment of the risk management information channel from top to bottom can ensure that the information can be transmitted and shared from top to bottom or from bottom to top, so as to ensure the accurate and timely transmission of information. The transmission of information needs the following conditions: first, there is a clear text that can be related to the risk control mechanism, so that those employees in the risk control mechanism can communicate with Curie; The second is that the risks that have emerged can be dealt with at an accelerated rate, and that information can be used between every department of the company and its managers.

After the improvement of the risk control mechanism, the enterprise should supervise and improve the implementation of the risk control in the future. These work need the close cooperation of all the staff and the management, and the basis of cooperation is that the employees can clearly understand their post responsibilities. Management can exercise supervision and guidance. And risk monitoring must have a dedicated body, such as a risk supervision and management team. The company itself has a low ratio of human resources to wind control. If a risk management chief executive is introduced to the management level, then the management can take the importance of risk management seriously. The Chief Executive Officer of risk Management will be able to put forward rationalization proposals when making risk decisions in the future H Investment Company, so that the risk crisis of the enterprise will be reduced, and the investors' investment will be guaranteed. The risk control mechanism must be combined with the risk prevention department to perfect the risk management.

In the eight elements of risk management, each element involves the executor, every link of the executor to do in place, risk management work twice the result with half the effort, so the executor factors are very important. There is also a wide range of risk awareness, prevention, control and decision-making, wide knowledge, and the need for high-skilled personnel in many fields. In this way, we need to focus on talents, according to the advice of risk prevention in many aspects, to be responsible for people's thinking, to increase the training of enterprise staff, to upgrade their skills, to enhance the quality of risk management of the team, and to create a cohesive force. Responsible, professional

knowledge of the risk management team. In addition, enterprises establish effective and practical training programs for all employees, so that each employee can mention the training time, increase the professional knowledge of those risk control personnel, and increase investment in skills education. So that they can keep up with the needs of the company and business needs, the quality of continuous improvement. In addition to the company's risk control staff training, but also external recruitment of those with strong professional skills to strengthen the company's personnel structure.

Generally speaking, the establishment of the risk management framework system of the company should meet the needs of the development of the company, mobilize and publicize the importance of risk management within the company, and raise the risk management awareness of all employees. Raise risk management to strategic management and set long-term planning goals. In addition, the paper analyzes the current situation and reasons of the company, and puts forward some suggestions for optimizing the internal operation process of the company. When supervising the internal operation process of the company, it should communicate and convey the information in time, strengthen the internal risk management mechanism, and improve the external risk supervision. Optimize the organizational structure and responsibilities of risk management and strengthen the training of talents.

7 Conclusion

With the acceleration of the integration process of the global economy, the internal control and risk management are an eternal theme for any country's enterprises. If administrators do not attach importance to the risk, it will seriously threaten the healthy development of the enterprise and even the survival of the enterprise, which will seriously cause the bankruptcy of the enterprises.

In order to drive the enterprises to pay more attention to ERM, this paper analyzes the various aspects of ERM from the elementary to the profound. After the generalization of the basic definition of ERM, this paper lists four factors which might influence ERM that are CFO, the board of directors, the industry that enterprise dwells in and components of the headquarters of the enterprise. And the paper also gives an ideal process of the process of ERM while putting emphasis on the stage of risk identification. By integrating information and citing appropriate examples, this paper aims to highlight the significance of ERM to the enterprises in today's economic environment.

Abstract: The main goal of this article is something that concerns to the corporate world that is working with social networks, more specifically the WhatsApp application, in mediating a business leadership proposal. More broadly, social networks facilitates the communication process, speeds and issues such as time as space for improvement in organizations because today we know the need for agile and effective communication, and for this, to work efficiently if should make use WhatsApp Business, a revolutionary tool that is changing the way organizations communicating with their internal and external customers, and have greater control over the results from this new tool. As a study contribution, effective use occurs with good connectivity with adequate and effective functioning, using a PDCA tool, whose approaches will be presented in the course of this work.
Key words: WhatsApp; Leadership; WhatsApp business; Connectivism; PDCA

1 Introduction

Many companies of the world already work their leadership model based on connectivity, by social network like Facebook, Instagram or more popular and conventional as WhatsApp. The main question about use of technology is not implicit only about facilities as speed and time given, but on the effectiveness of the actions, process and ways of work using applications. What more bores the group's administrators is the organization of them, besides the respect about the established rules for efficiency on the processes of leadership applied to optimize the activities in the companies.

The applications in a general way facilitates the communication process when applied in benefit of the company, but must have their rules and for this must have good leadership that many times passes on the basis the leading format and has to be respected by the whole member of the construction process for excellence of leadership in a connectivity purpose.

The applications in general facilitate the communication process when well applied to the company, but must have rules and for this must have a leadership.

The ideal based on the purpose is working with small groups of at most 50 persons to have homogeneity of language, when it come subjects and collaborate to improve the leadership process in the WhatsApp group.

In a general sense, the social media have shortened and improved the distances on communication. Nowadays, the messages are answered instantly, with the possibility of instantly receipt too. The actor of nowadays has been bombed with information beyond of what researched by many information sources. This is because telephone that before was a set to make and receive calls nowadays has many applications. A Social Media Apps (SMA) found a way of entering the work environment by the computer, tablet or IPhone and Smartphone, online and all time.

WhatsApp is an example of one of many applications that comes standing out concerning the user membership for personal use and recently for professional use too. Here in Brazil we have reached the mark of more than 1 million users only in 2015 (Carvalho, 2015), arousing interest of the organizations for this tool, and what was personal, migrated to the professional quickly. Business conduction has been done by SMAs, that strengths relationship between leaders and employers, customers, and narrowed providers and other companies. Although it may be identified on the researches made, in different fields of science, it is not noticeable yet, for the researchers, indications referring to the frequent utilization of the social networks during work (Rinker, Bessi, 2015).

In contrast, using the social networks for performance of the work's activities generates repercussion on labor courts, once employers do allege that misuse of this tools at work period and worker, by another hand allege that the app has been used as a vehicle for tasks that demand additional

hours beyond the pre-set time by theirs employment contract. A fact, that became observed, is that WhatsApp has been used by professional purposes, modifying the routine and efficiency of working communication, improving this into organizations. The inclusion of new technologies are changing the nowadays scenario about working day, and carrying effects in the way as workers are relating with their work's activities, observing that occurred increasing instability this way. The main proposal of this project is related to (PDCA) into the group of WhatsApp, collaborating significantly for that the leadership be aligned to the established strategies in a work with the proposal approaching connectivist leadership.

With this is expected for companies are more efficiency and excellence of productive processes by using the app on leadership processes.

This work searched identify the changes promoted by the use of app WhatsApp potentialized by PDCA tool in a corporate environment. After the contextualization of the research object, occur the review of text and then the demonstration of methodological procedures, followed by the socialization of the conclusion of their authors.

2 Theoretical Revision
2.1 Social Networks, Apps and their importance for the communication process in companies through the WhatsApp

WhatsApp has its source from California (USA) in 2009 by two persons that, together, have spent 20 years working on Yahoo! before founding WhatsApp. Their names are: Brian Acton (American) e Jan Koum (Ucranian) with the objective of replacement the SMS. Its principal function is exchange messages by cellphone, just having a date plan of internet and a Wi Fi network (Carvalho, 2015).

The app works in iPhone, BlackBerry, Android, Windows Phone, Nokia and Sim.

It allows create groups, changing written dates or figurative beyond audio, therefore, one complete tool for dissemination of information from mobile to mobile.

In 2014, WhatsApp has been sold to Facebook – strongest world's social network – by approximately 16 billion dollars. Their founders were introduced yet to the Board of Directors of Facebook (Carvalho, 2015).

These 2 giants joint venture of social network collaborated significantly for the propagation of information and facility of connectivity among people.

An important factor that must be viewed is that WhatsApp is a free app and, therefore, facilitates connection of people encouraging many people have this app in his mobile.

Second Oliveira et al (2014) in Saccol, (Shlemmer and Barbosa, 2011):

Learning processes based on usage of information technologies or communications mobile wireless, which main characteristics is the mobility of the apprentices that can be far one of each other and from education formal places, like training classrooms or place of work (Oliveira et al, 2014, p. 23; Barbosa, 2011).

Practicality of the app is in the fact the student doesn't need to be in the same physical place the teacher, and so this kind of education may be propagated by M-Learning in real time so that the student can open texts, illustrations, pix and audios any place, since he is connected to a mobile network of internet.

These advantages may be seen on the table down:

Table 1   Advantages Using WhatsApp for Learning

Practicality	The content can be accessed from any place since it has a Wi Fi network and internet
Cost	There is no cost being a free app
Autonomy	The person who belong the group may access any hour of the day, because the dates are stored.
Leadership	Always we deal about learning processes, teacher must be the mediator of the subjects with participation of the students.
Organization	The guidelines and subjects must be organized by group with professor's help.
Interactivity and participation	Everybody can contribute for the elaboration of the questions and solutions.

2.2.1 Practicality

The app WhatsApp is a model of network where inedible can access from where they want, including around the world, just have a Wi Fi network for connection and one internet wave, practical for people who want access their dates wherever they are and at moment they want. Everybody can see texts, open pix, graphics and tables, hear audios an also pass on doubts interacting with another people of the group and yet building information with other members.

2.2.2 Cost

For many times it has been tried to charge the app utilization, but it is a free model without costs where inedible, accessing and downloading the app, can create many groups that can be for studies, professional or even entertainment.

2.2.3 Autonomy

The question autonomy depends on which group the person participates, because the group work may be scheduled at times and accessibility, therefore, the configuration variables of study, if scheduled, must be discussed by the group and their members.

2.2.4 Organization

Another point to be elaborated is the organization of ideas willing in the group of WhatsApp that may be worked with a mediator teacher of the established information by items (subjects) where students interact and collaborate for the creation of contents at the same time they can solve their doubts with the professor, as also help other participants towards the construction of the knowledge in a scheduled form, that is, by items to be explored by the group.

2.2.5 Interactivity and participation

Everybody must interact in the group for it to become a collaborative tool of learning construction. Teacher perhaps will not be the main agent of this, because the pupils, having doubts may have help from other participants through the collaboration of other members of the group. The essential is collaborating somehow, being doubts or solutions for the problems on schedule. By this purpose of education and learning about inserted contents in the group will have an effect much more productive and assertive on construction of improvements about the subjects addressed in the research group.

2.3 WhatsApp and his creator

Jan Koum, creator of the WhatsApp was born in Kiev, a small city in capital of Ucrania and had a childhood without liquor or stewardship and his home nor hot water had. When he has migrated to USA when seventeen, he could survive with food coupon and nowadays, will become a millionaire of the Silicon Valley, because the company founded by him five year ago, WhatsApp will be, certainly, the biggest acquisition of the Facebook history.

Koum signed an agreement of US$ 19 billion in the social center he used to attend with his mother, place where they received the food coupons, responsible for their subsistence at the first years they have spent living in USA and, this way, it worth point out that they moved to America escaping from the Soviet Ucrania tensions as so try to find better future prospects. This brilliant boy is a housewife and a master of works, both already dead, and the attitude and profile of Koum are, surely, an antithesis of what is expected in general from a new multimillionaire from what can be named the Technology 'Meca', the famous Silicon Valley, in California.

This entrepreneur, only 38 years old is, with no doubt, a man of simple habits, and extremely carefully with his intimate life, with solid principles, with relevant ideas, of which it does not intend to depart, although the owner of a company that has the collaboration of   55 employees and becoming an acquisition of the gigantic Facebook, that is known as the most popular social network, with the antagonistic philosophy in in several respects, relevant to the spirit that Koum has developed the most popular instantaneous message service that world has already noticed.

Koum and his partner Brian Acton, created WhatsApp, a free of adverts and related platform that the users hate in the technological world and this new tool take the Yahoo! users to abandon this. For the creators of free instantaneous   message service for universal Androids and Iphones , there are two red lines that weren't exceeded, not even by the   multimillionaire value that Facebook paid by his, up until, small company, however, analysts consider this amount paid a little exaggerated.

Private life of Koum and his childhood and adolescence in a country where it was looking for communications relevant to citizens as well as their privacy, were the precursors of the idea and assured, since WhatsApp beginning, for about five years, this app is able to collect less amount of data of their users who need their cell number only to be possible that their identification, and so, access the service. It's interesting that privacy, particularity of the app collides with the Facebook philosophy that has the striking feature expose the life of their users as an opened book and it was precisely on account of these

dates that achieved too much profit and by this way the social network made a market segmentation, impossible to measure this value.

The fact is thatKoum exactly with the intention free the users of WhatsApp of the usual avalanche of advertisement coming of other platforms, as with his own Facebook, was a prerogative of this self-taught entrepreneur known, by the way, that was a rebel student and that left university before concluding his studies to ingress at Yahoo!.

Mark Zuckerber, Facebook owner, affirmed that will respect, in principle, the goal of do not incorporate advertisers, but yes, do capture new users and on account of this affirmative, Koum and Acton accepted the commercial agreement once Mark won't commodify the differentiated communication service that both offered their users. The young millionaires entrepreneurs are convinced that it will be possible keep the principles, even their company pass to be property of Facebook, surely the social network, on its tenth birthday, that as gift had their acquisition of WhatsApp, keeping attractive to the public, mainly the younger, and keep on sticking its passage to the cell (Carvalho; Carvalho, 2017).

2.3.1 WhatsApp and Slack: group message improvement

One of the problems when using the famous group's on WhatsApp is the inundation of messages that happen in the associations of their users. It is simple: how much more the number of people in a group, bigger the probability in interaction between members multiply with ones with subjects where they think urgent. For some of them that will work until midnight oil, for example, the situation bordering unbearable chaos because, besides the cell has thousands of messages not read, there is also the problem that the battery that through the entering of messages it unloads quickly. It's only one hour away from de cell to create a chaos also including the cell owner that will not have battery.

Trying to solve this disorder, WhatsApp created a new tool that search precisely make easier the administration of innumerable messages exchanged by members of the group. It was titled as *group catch up*, and it is localized in the right corner, at the bottom of the screen, and it can be identified by the "@" (arroba), being that this function allows the user hand the uncountable messages, identifying only at the moments that the user is mentioned on the messages exchange. In this sense, it is easier to reach the parts more pertinent of the chat to the user. There is also another function disclosed by the company, that are the questions with more specifications in reference of the groups configuration only for administrators and, in this sense, only the responsible for the creation of the group can introduce some controls like allow who can change some icons or same the name of the group.

Some proposal to update the app are great and have been created to help and to develop the groups dynamic, as well as help the privacy of members disabled of participating chats during the business hours, for example, or during important meetings. The curious thing is that these ideas had been created and performed by Slack some time ago, like activity notification tools or searching, incorporated to the internal communication program for corporations, centered on the functions like all threads or show activity, tools that search keeping a good cooperation rhythm, that must be constant in the groups that host.

WhatsApp via Slack will increase time limit to include member after it has been excluded or left the group, in order to reduce many possibilities of harassment or *spam* on the platform. The update packet will be available for iOS and Android systems (Carvalho; Carvalho, 2017).

2.3.2 WhatsApp Business

The company developed an app focused exclusively in small and medium-sized enterprises. This app baptized as "WhatsApp Business", with resources that aim to make the entrepreneurs life easier and who search to meet, with primacy their clients by smartphone. It is the result of a crossing between WhatsApp and Slack, commonly known as being a message app that has intelligent resources. This friendly interface had a sober version for companies, but has kept the simple resources for final consumers, as it used to be in the app.

Bellow the main resources of this communication tool

(1) Quick message

Messages Automation: it is possible to configure shortcuts, like "thanks", with the intent of creating thanks texts, valuing the company and reflecting their values. Beyond the automation, there are message for the absence periods too.

(2) Profile

In WhatsApp Business it can be developed the profile of your company as it was a business card for many potential consumers that can come to the enterprise by this new communication channel.

(3) Metrics

It is a statistics menu. It's simple but is a tool for measuring the usage of corporate account in the

organizations. It's possible to view dates pertinent by the sent messages, received, handed out and also read ones.

(4) Hang tags

Also used for messages identification. The idea is using markers lik 'paid' or 'new client' or even about outstanding payments, between other particularities. It also can ad new hang tags, only initializing a new talking, choosing the option reference "ad new hang tag" (Carvalho, Carvalho, 2017).

2.3.3 Connective Leadership and the use of PDCA (Plan, Drive, Control and Evaluate) WhasApp groups

Among many tools of quality, the PDCA is one more widespread and its usage must be seen with caution. Smith (1988) highlights that, in general, the managers tend to apply such tools rather than think about the real solution of the problem. And this can occur due the necessity for obtaining quick results, applying these tool and technics.

In fact, it is much simple than thinking jointly with the Direction on understanding the solution of problems pertinent to quality.

In reference of the technology and apps of WhatsApp, it worth to emphasize that software developers companies are already watching in this app, already widespread among organizations and in this sense, the PDCA will transform PDCA the WhatsApp Business in a tool that will aggregate too much in this app, providing much control and quality, helping the organizations to leverage their business with much more efficiency and quality.

According to Mattar (2013):

Although some authors argue the connectivism mustn't be considered a new learning theory […] The connectivismor learning distributed is purposed by a much more proper theory for the digital era, when is necessary action without personal learning, using information out of our primary knowledge.

This is a relevant and significant fact that must be observed in the companies, because there are people with differentiated cognition about leadership, as well as different models of leaders. So the application of a connective one will depend on many elements that collaborate for the development of this leadership, even if it's based in a active learning where the individual understand the importance of working with mobile.

The connective leadership will work with aspects used on the real world into the app making that de virtual structure is appropriate to the classroom. There are already formal and informal groups that have leadership, as standards and rules established for the utilization and also to be part of the group.

According to Coll (2004) the development consists on the construction of series of structures that determine the nature and breadth of people's exchanges with their medium that, besides this, invariably happen respecting the tendency towards a better balance.

The medium in question is the virtual, through the WhatsApp group, the changes are necessary for good progress of the group, it's up to the leader, by the connectivism be capable keeping the order and do that the planned and expected actions occur through the established exchanges into the virtual environment.

3 Methodology

This study was developed considering a qualitative approach, seeking to value the context that individuals attribute to it (Flick, 2009).

This article was elaborated through a bibliography research, involving articles, sites and books, interpreting their real theoretical contributions (Gil, 2008). As proposed analysis, it was applied a line of reasoning and PCDA model in WhatsApp use.

3.1 How the Project WhatsApp using the PDCA is based on?

(1) Diagnoses

Nowadays there are problems of time and space for information. The idea is create leadership groups in the companies for that the actions can happen in short time and distance without the individuals need be together in the organization. Most of these waste time when the subject is leadership because they need his leader be present to give information to their contributors and the proposal is work with WhatsApp optimizing questions towards these aspects.

But for this to occur the created group for connective leadership must be well structured in a way that people do understand how work by this tool searching for proper quality in the virtual work proposal.

(2) Action

When creating a group specifically to work with leadership based on conectivism the responsible or leader will have to set purposes establishing standards, usage rules as well as goals to be achieved into the work proposal. Thus facilitating the leadership and empowering the exchanges into the app for productivity improvements.

(3) Implementation

The group will be created according the necessities of the enterprise and of the work team; it is suggested that it can't be a bigger one so the leader, by the conectivism can work with dates, planning the content, achieving drive the actions and talks into WhatsApp, controlling the information flow in a time lapse.

(4) Going along

In a WhatsApp group is important keeping focus when do exist a project of leadership, therefore is fundamental monitoring that the leader verify if the subjects really refers to the project, if the persons are participating of the construction process not only of leadership, but of the ways of working and check if the standards of the group are being respected.

(5) Validation

The validation of WhatsApp group will be done according the achievements done by the team within a proposed time on some project and what can be validated is if the use of the WhatsApp tool, trough the leadership, based on connectivism can optimize the leadership processes of a team bringing quality to it.

(6) Evaluation

In this part of the Project it's up to the leader and their led ones establish a clear communication where will be cleared in it what did not go as it should, if there was something behind that could be improved, some settings to the next one using the mobile so as not to happen again.

(7) Feedback

It's important emphasize that the whole involved in the connective leadership project using WhatsApp must be informed about the results and for this it's up to the leader after the end of this inform the team members how was the result using the app.

4 Conclusion

The conclusive dimensions point to for signifying tendencies with respect to constructs referring to personal relationship in organizational environments, as so as in the structure of the organizations. If the intense use of the app is positively valued in reference of its agility to contact people, seek to solve problems and search decisions, in contrast, it has been criticized as regards aspects not fore seen in its unplanned organizational accession intensifying, this way, the absence of organizational boundaries that are not clear. This way is explicit that the critical point is why not its use.

Thus, the app was inserted in the in the everyday organizational environment as a new communication model without being regulated by institutional norms. Because of this, it is observed that the lack of formal internal procedures occurs because of the novelty: organizations did not have time yet to adapt to this tool and, that is why did not formalize institutional norms, then, it can be affirmed that, unofficially, occurred an incorporation of the app by physical persons. It is a simple question, and this is because it is an intimate forum or, maximum it can be affirmed that is a peer negotiation, that choose to answer, or not, a message. If this scenario is taken to the organizational scope, it can be got complexity in its amplitude, because questions like authority line, hierarchy and responsibility, decision power among others are launched.

This point is convergent because it anoints the *emergence* of the contents belonging to horizontalizationand empowerment of people on WhatsApp groups. This way, these contents indicate changing taking place in 'real' structures of organizations that happen in the world, perceived internally in the organizations. These are related to personal and interpersonal changings that people discover, occur with the app utilization since it is from the same that organizational change have been built.

In this sense, individual perceptions are distinct, because there are ones that can't more realize their tasks the same way, changing their routines since they are permanently seen stimulated by the tool: some of them they serve customers till midnight oil and many times do not know how to deal with certain issues with the company; other ones arbitrate different cases, assuming the risk of their bosses among others situations.

The perceptions related to productivity are very varied. Therefore, the WhatsApp normalization by PDCA is imminent, a short way without return. The purpose of this study was precisely to demonstrate

the this tool use that is growing in a frightening way around the world taking organizations begin the use of it, baptized as WhatsApp Business and its resources in order to make easy business life, since attending with success their customers, suppliers and contributors through the use of Smartphones and IPhone. The new version of this app for organizations has been optimizing time and consequently minimizing costs given that it is a free one.

The fact is that many nowadays of space and time problem with information is leading executives create leadership groups in the organizations the way to optimize time and short distances among inverted staff. In this sense, managers that need send information to their subordinates, customers and suppliers quickly implement WhatsApp Business, taking care of questions directed towards space and time instantly.

And for this, just create a group focused on convective leadership, well structured, together with the administration tool, PDCA, so that those involved have cohesive and effective groups for all learn and understand that WhatsApp is more than an entertainment app, a value tool that search adequate quality in a virtual work proposal and it is and it is undeniable to affirm that these are the future organizational tools: very soon, the whole organizations will use WhatsApp Business along with PDCA to administrate and measure the organizational groups in an efficient way, with more profitability at lower cost.

The results of this work point to the necessity of future studies in an interdisciplinary perspective with more deepening the areas of Information Technology, Organizational Studies and People Management, in that the results are related to a new way of organize groups, manage people, beyond consider themselves very important leadership, being formal or informal, as well as the organizational structure and behavior are of major importance on WhatsApp and PDCA thematic tools.

Linking Ethical Leadership, Value Congruence and Employee Creativity

Muhammad Anwar ul Haq[1], Mirza Muhammad Ahtisham[2]
1 Assistant Professor, Department of Management Sciences, University of Gujrat, Pakistan
2 MPhil Scholar, Department of Management Sciences, University of Gujrat, Pakistan
(Email: anwar.haq@uog.edu.pk, 17111720-002@uog.edu.pk)

Abstract: The aim of this paper was to examine the effect of ethical leadership behavior on followers' creativity. The linkage was investigated with the mediating role of value congruence. The data were collected from 200 employees working in diverse industrial sectors in Gujrat. Data were analyzed using SPSS 22. We used Hayes process to statistically test the mediating effects. The results show that ethical leadership has a positive significant effect on employee creativity. The results also show that mediating effect of value congruence was statistically different from zero. These results have important theorical contributions and managerial implications. Lastly, we recommend longitudinal design for future research.
Key words: Ethical leadership E; Employee creativity; Willingness to take risks; Value congruence

1 Introduction

In the present times, there are rapid changes in the world of technology. The changing technology has shortened the product life-cycles. In order to cope with the competitive situation, companies need to be innovative. Organizational novelty or overall creativity is enhanced by personal creativity (Zhou & Shalley, 2003), which is prejudiced by personality characteristics or by the organizational environment. Consequently, the leaders' role is important. They have deep insights into followers' work and can influence the work environment (Shalley & Gilson, 2004). Various authors have explored leader impact on employee-creative-behavior, focusing on leader–member exchange (Tierney, Farmer, & Graen, 1999), empowering leadership, and transformational leadership (Zhang & Bartol, 2010), but insufficient studies have been conducted on the relationship between ethical leadership behavior and creativity. (Chughtai, 2016) found the relationship between ethical leadership and creativity to be positive and he also reported that authentic leadership nurtures environments that encourage creativity. Nevertheless, there is still a scarcity of research into the process of the effect of ethical leadership behavior on employee-creative-behavior. According to Amabile and her colleagues' intrinsic motivation theory (Amabile, Conti, Coon, Lazenby, & Herron, 1996), intrinsic motivation is also a significant mediating variable in the creativity process, environment affects work force's intrinsic motivation, and this, in turn, affects their creative behavior. The creative process is full of uncertainty and work force must be willing to take risks. Within organizations, risk taking is a willingness to accept challenging tasks to yield positive, organizational beneficial outcomes while being receptive to negative consequence at a personal level. It has also been demonstrated that willingness to take risks is a significant predictor of creativity (Dewett, 2007).

Rokeach (Rokeach, 1973) defined the value concept as "an enduring belief that a specific mode of conduct or end-state of existence is personally or socially preferable to an opposite or converse mode of conduct or end-state of existence". All other values and measures of integrity are based on are called principle values, they are the foundation upon which rest of the values are relied. Among various types of values that may include moral or ethical values, religious, political or ideological values, aesthetic values or the communal or social values. Values may be thought as being hierarchical in nature, in the need to discover the idea of being a value system. A value system is a set of rand ordered values. Which may be heavily disheveled and look on an individual's personal values and independent and cannot meaning fully explain the values of another person or individual. In early life stages, values systems tend to be formed and are very stiff in nature i.e. are very stable. Many longitudinal research studies on values have generally shown the remarkable stability (Rokeach, 1973). A person who observe obedience as his or her value is very unlikely to believe that being disobedient is preferable that being an obedient person. To bring a change in value systems, requires a rearrangement of the relative importance given to the other values (Krishnan, 2008). Same in the case of Organizational values, which are defined as "criterion for work force's evaluation about events, activities, and persons desirably or undesirably". The subjective and internal side of any culture is formed by organizational values all over the world. It indicates that organizational issues can be seen as being solved by values as acceptable and convenient. General aims and standards of any subject organization can be reflected by its organizational values.

They make the individual's personal values and organization's values congruent with each and to complement and supplement each other. Organization causes work force to want to imitate the behaviors which serve reaching aims (Krishnan, 2008).

  In this research paper, we had aimed to answer whether in an unethical work environment under unethical leadership, work force' are willing to take risk and show creative behavior. Do Ethical leaders always show support and allow risk taking? Outcome of such risk can be either positive or negative. Given the importance of willingness to take risks to the creative process, we wanted to explore the mediating role of value congruence in the relationship between ethical leadership and employee-creative-behavior. In all, the purpose of this paper is to contribute to the Pakistani as well as international knowledge by examining how unethical leadership impacts employee-creative-behavior through the mediating role of value congruence.

2 Literature Review

  According to Northouse (Northouse, 2012), ethics is an essential part of leadership. Ethical leaders support and reinforce organizational values. Leaders, consequently, have an important influence on the values created by the society in general and by the organizations in particular. A kind of leaders who give respect to others, allow them to be themselves and behave like their true nature, with cooperative support, convey a sense of absolute value and gratitude of their contributions.

  Ethical leaders highlight the implication for respect. According to Northouse (Northouse, 2010), respect entails tolerance to the opposing opinions, listening carefully to fellows, and empathizing the differing scenarios. Kant (Kant, 1981), however, warned that it is inappropriate to deal a person merely for personal means. A central issue here would be that whether workforce is also obligated to moral rights. Werhane et al. (Werhane et al., 2004) opined that all employees must be entitled to moral rights. In the provision of rights, no cultural or religious biases should be considered. The employer's obligations and worker's right should be integrated (Maitland, 1989). According to Ariss (Ariss, 2003), one of the prime rights of employees in the workplace is well-being and safety. An ethical leader is a torch-bearer of provision of moral rights to employees in the workplace.

2.1 Ethical leadership and employee creative behavior (creativity)

  Chen and Hou (Chen and Hou, 2016) found that "ethical leadership facilitates employee voice behavior, thereby enhancing employee-creative-behavior". High moral standards to the workforce are conveyed by the ethical Leaders, and the raised voices against problems and concerns regarding products, services, and processes are a demonstration of encouragement from certain norms and behaviors of the ethical leaders. Hence, we can state that the absence of the perspective of ethical leadership or presence of unethical leadership will discourage employee-voice-behavior, thereby reducing employee-creative-behavior. Ethical leadership and creativity (Ma, Cheng, Ribbens, & Zhou, 2013) examined the impact of ethical leadership on employee-creative-behavior. They used a multiple mediation model on a sample of work force and supervisors from four Chinese companies. The authors found that "ethical leadership was positively related to employee-creative-behavior, and that knowledge sharing and self-efficacy mediated this relationship".

  Risk taking behavior involves accepting the challenging tasks and taking decisions accordingly in an effort bring positive changes in the workplace. Risk takers do so regardless of the negative outcomes at personal level (Dewett, 2004). Creativity is a high-risk activity, often with a high probability of failure. Only when work force has the willingness to take the consequences of risks are they likely to exhibit creative behavior. Several scholars have highlighted the relation between the willingness to take risks and creativity (Farr, & Klein, 1997).

  Risk taking behavior is a function of organizational environment and style of leadership. It has been argued that leader's style is a point of attention for the followers and they spontaneously react towards it (Tyler & Lind, 1992). For socially distant leaders, the reactions of workforce are far from risk taking (Edmondson, 1999). Ethical leaders lead the workforce according to organizational values, guide workforce to predict future requirements, and help them take risks. Furthermore, ethical leaders are respectful to their followers and give due consideration to the opinions of the followers which breeds positive behaviors in among them, such as creativity. Likewise, ethical leaders also affect outcomes, such as risk-taking behavior (Turner Parish, Cadwallader, & Busch 2008).

  In an increasingly competitive market, managers often confront ethical dilemmas. Enderle (Enderle, 1987) was the first one to propose the idea of ethical leadership. He defined it as a way of thinking highlighting the various dimensions of decision making. It was advocated that the ethical standards be

integrated into managerial decision making. Treviño, Hartman, and Brown argued that ethical leadership contains two elements: the leader as an ethical person, and the leader as an ethical manager. Treviño, Brown, and Hartman listed five elements of ethical leadership: setting ethical standards, taking ethical action, people orientation, performing ethical decision making, and expanding ethical awareness. Brown (Brown, 2005) drew on social learning theory to define ethical leadership as the use of encouragement mechanisms to inspire ethical behaviors among work force. "With regard to the impact mechanisms of ethical leadership, findings in studies show that leaders can positively affect employee outcomes" (Avolio & Gardner, 2005) and organizational citizenship behavior (Rego, Ribeiro, & Cunha, 2010). Furthermore, ethical leaders can be tasked to develop a culture based on values and practices considered to safeguarding interests of all stakeholders (Huhtala, Kangas, Lämsä, & Feldt, 2013). Toor and Ofori (Toor and Ofori, 2010) found that ethical leadership correlates with greater job satisfaction and with work force' willingness to expend extra effort. In all, findings reported by scholars suggest that ethical leadership positively affects work force' work performance and job satisfaction and promotes positive employee extra role behaviors. Consequently, we proposed the following hypothesis:

Hypothesis 1: Ethical leadership will be positively related to employee creative behaviors.

2.2 Ethical leadership and value congruence

According to social identity theory, desire for association with individuals, groups, or organizations is a means of fulfillment of shared motives. The individuals associate themselves with whom their values hold similar (Ashforth & Mael, 1989; Tajfel & Turner, 1985). It provides that employees assess the level to which their characteristics identify with the organization and its members while deciding to establish the association with the organization. Likewise, ASA (attraction-selection-attrition) model proposed by Schneider (Schneider, 1987) argues that people are attracted towards, selected in, and remain in the organizations which they find the best fit with of their personal preferences.

"Values" are one of those personal characteristics/preferences which employees consider to equate with their peers and their organization (Lee et al., 2009; Schwartz, 1992). According to Cable and Judge (Cable and Judge, 1996), values are beliefs that a specific set of attitudes and behaviors is preferable over its opposites. These values, hence, guide actions. According to Lee et. al. (Lee et. al., 2009), values are central to one's identity. It is highly likely that people would develop and strengthen relationships with the ones they think that their values are aligned. Empirical evidence provides that individuals would tend to apply for job in the firms that have parallel values (Chatman, 1989; Judge & Cable, 1997; O'Reilly, Chatman, & Caldwell, 1991). Analogizing, ethical leaders would establish similar values in their followers. Hence, we propose that:

Hypothesis 2: Ethical Leadership is positively related to Value Congruence.

2.3 Value congruence and employee creativity

As suggested in the literature, the "dark side" of value congruence, namely how value congruence affects personal creativity and organizational novelty, has not yet been examined empirically. The dilemma is that firms need diversity to boost their creativity and also a global norm and culture to coordinate work force' efforts. The symbiosis of diversity and fit within firm can be a fruitful field (Powell, 1998). Consequently, we proposed the following hypotheses:

Hypothesis 3: High Value Congruence have positive effect on employee creative behavior.

2.4 Mediating role of value congruence

As association with an organization becomes part of an individual's identity, so do the shared values between a leader and follower explain how a leader's behavior influences follower attitudes and behaviors (Ashforth & Mael, 1989). The followers may use information about ethical standards of a leader to predict the values, attitudes, and behaviors of leader (Hogg, 2001). Leaders' values are a better representative of firms' value than others. It may be inferred that an ethical leader would espouse values such as communal responsibility, fairness, and integrity. Contrarily, unethical leaders would practice values such as inequity and selfishness (De Hoogh & Den Hartog, 2008). Hence, prospective employees who share similar values with an ethical leader would more like to establish and retain employment relationship with him/her rather than with unethical leader. This goes in a fashion that value congruence would mediate between ethical behavior of a leader and job pursuance behavior of follower. This proposition is confined to certain conditions however. The values of an ethical leader are unique and may not necessarily be shared in entirety by all the followers.

Hence, those leaders who share the values of creativity and innovation with the followers would attract more creative follower and influence their behavior. Further, it is argued that perceived value congruence would potentially intervene between leader's ethical behavior and follower's performance. Ethical leaders personify certain specific principles which might not be imitated by all the followers. It

is however also notable that all the follower would not place equal emphasis on the values such as communal responsibility, fairness, and integrity as does an ethical leader. Hence, the following hypothesis is proposed:

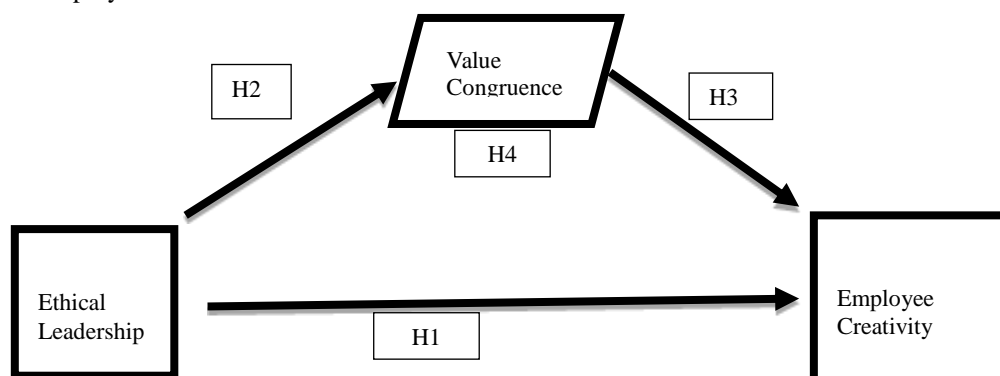
Hypothesis 4: Value Congruence positively mediates the relationship between ethical Leadership and Employee creative behavior.


Figure 1   Conceptual Framework

3 Methodology
3.1 Participants
We collected survey data from 200 work force including front-line managers, Middle managers, Top Managers and workers working in various sectors of economy i.e. Telecom, Insurance, Banking, Hotel, FMCG, Retail, Financial Institution, Hospitals, Electronic Media, Education, IT (Information Technology), Print Media, etc. Each participant was briefed about the purpose and taken consent before filling this self-administered survey. The sampling technique used is non-random sampling as the actual population size is unknown.

3.2 Sample
The frequency distribution tables show that highest number of people were from telecom sector, computing to be of 37 percent. Followed by 21 percent from banking sector. Where, over 50 percent of the respondents were working in the operations departments of these firms. Over 70 percent of respondents were male and the most populated age group was 30-40, comprising on over 50 percent.

3.3 Measures
Ethical Leadership: We measured ethical leadership using the ELSQ (Ethical Leadership Style Questionnaire) scale developed by Brown et al (2005), in which the developers used four dimensions of character: integrity, altruism, collective motivation, and encouragement. An example of an item in our survey is "My supervisor can always make a fair and impartial decision." Cronbach's alpha coefficient calculated for the 12 items was 0.82 respectively.

Employee Creative Behavior: We used the Individual Creative Behavior Scale developed by George and Zhou (2001), which comprises 8 items. An example of an item is "Can come up with new methods to achieve a work target." The Cronbach's alpha for the modified scale was 0.79.

Value Congruence: We used the Q-POVC (QUESTIONNAIRE of personal and organizational values congruence for employee) Scale developed by (Vveinhardt, Jolita, Gulbovaite, & Evelina, 2015), which comprises 8 items. The Cronbach's alpha for the scale was 0.71.

4 Data Analysis
We used SPSS 25.0 to perform description, correlation, and regression analysis. For mediation, Hayes Process Macro 3.0 was used. For single mediation, model number 4 was suitable.

5 Results
5.1 Measurement model
First, we assessed the measurement model to confirm the factor structure of constructs in the model. Both the local and global fit values were within the threshold. Indices of local fit were within the range (χ^2/df=2.313, CFI=0.953, TLI=0.917 RMSEA=0.38). Similarly, for global fit, loadings were also

significant and above 0.50. Furthermore, we also tested an alternative model to verify if there were any alternative best fitting model(s). All the constructs were combined and a model with single construct was tested. The model did not show proper fit. Hence, our hypothesized model was accepted.

5.2 Descriptive

Below is correlations table showing relationship between constructs. The table shows that there is a significant positive relationship between ethical leadership and employee creativity (corr=0.311, p<.05). The relationship between ethical leadership and value congruence (corr=0.263, p<.05). Similarly, employee creativity and value congruence also showed a significant positive intercorrelations (corr=0.276, p<.05). The table also shows reliability, Cronbach α, of constructs under study. The Cronbach α of ethical leadership was 0.82, employee creativity was 0.71, and for value congruence was 0.79. All values were above 0.70 which is the threshold value.

Table 1   Reliability and Correlations

	Cronbach α	EL	EC	VC
EL	0.82	1		
EC	0.71	.311**	1	
VC	0.79	.263**	.276**	1

**. Correlation is significant at the 0.01 level (2-tailed).
EL=Ethical Leadership, EC=Employee Creativity, VC=Value Congruence

5.3 Hypothesis Testing

Hypotheses were tested using Hayes Process Macro in SPSS. Test was performed with 2000 bootstrap samples. H1 proposed that ethical leadership has positive effective on employee creativity. Results showed that there is a positive effect of ethical leadership on employee creativity (β=0.273, p<0.001). The bootstrap confidence intervals were also statistically different from zero (LLCI=0.1566, ULCI=0.3910). H2 proposed that ethical leadership has positive effect on value congruence. The results also showed that the H2 stands accepted (β=0.217, p<0.002). This effect was also statistically different from zero (LLCI=0.1056, ULCI=0.3290). H3 proposed that value congruence had positive effect on employee creativity. The results also provided the same (β=0.222, p<0.007). The bootstrap confidence interval was also statistically different from zero (LLCI=0.0783, ULCI=0.3665). Lastly, H4 proposed that value congruence intervenes between ethical leadership and employee creativity. The bootstrap samples provided that mediating role of value congruence was significant and statistically different from zero (β=0.116, p=0.001, LLCI=0.0136, UCLI=0.2447).

Table 2   Result of Hypotheses

Path	Coefficient	Standard error	LLCI	ULCI	P-value	Decision
EL→EC (H1)	0.273	0.0594	0.1566	0.3910	0.000	Supported
EL→VC (H2)	0.217	0.0566	0.1056	0.3290	0.002	Supported
VC→EC (H3)	0.222	0.0731	0.0783	0.3665	0.007	Supported

EL=Ethical Leadership, EC=Employee Creativity, VC=Value Congruence

6 Discussion

This study examines the mediating role of value congruence between ethical leadership and creativity for the very first time. This study expands the previous literature in the domains of ethical leadership and creativity. The results show that ethical leadership has positive effects on creativity. These findings are consistent with earlier studies which proved that ethical leadership affects employee attitudes and behaviors (Brown et al., 2005; Loi, 2012). Our results are also in line with Mayer et al. (2009) who established that there is a positive effect of ethical leadership on employee job performance. Establishing upon cognitive mechanism, we also showed that value congruence is a mediator between the ethical leadership and employee creativity.

This study also established that social identity theory is an important framework to explain the linkage between ethical leadership and employee creativity. Earlier, the researchers (Loi, 2012; Walumbwa et al., 2011) recommended that there should be further investigations into the mechanisms intervening between leadership and creativity. We found that ethical leadership has positive effects on value congruence and in turn it affects employee creativity positively.

Our findings suggest important guidelines for managerial practice. Managers should cultivate an

ethical environment in their workplace. While establishing an ethical environment, they must exhibit creative behavior. Those employees who identify with their leader's behavior would also engage in creative behaviors. It becomes imperative for the leaders to become ethical role models. They must establish those human resource practices which emphasize on ethical conduct.

7 Conclusion

A few issues limit the generalizability of finding. First, we rely on cross-sectional design which is detrimental to claim about the direction of causality. In cross-sectional study, we cannot control the temporal order of precedence. The future researchers should follow the longitudinal design. Second, we collected data from 200 respondents. Lager samples will provide reliable conclusions. Third, we used single source data. Single source data are prone to common method bias. We recommend the use of dyadic measures to future researchers. Fourth, for value congruence we relied on individual level. Group level evidence may provide more interesting conclusions.

Measuring the Workplace Stresses and Their Impact on Employees at an Automotive Manufacturing Factory in Wuhan

Takashi Watanabe[1], Ryuhei Yamada[2], Luo Fan[*], Xu Ruihua[1]
1 School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
2 Department of Interpersonal and Social Psychology, Rissho University, Tokyo, Japan, 141-8602
(E-mail: LBMwatanabe@gmail.com, ryuhei10ymd@gmail.com, sailluof@126.com, xuruihua10@163.com)

Abstract: The purpose of this study is to conduct a psychological analysis of mental health issues and causes of resignation (leaving job) at an automotive factory in Wuhan. The method will be clarified by comparing the psychological stress data of employees who left work and those who continue to work at this factory.The t-testsconducted through cross sectionindicatethat the workplace stressors and employees' job turnovers are influenced by the psychological impact to the employees. The findings will indicate tothe management team to improve employee job turnover by facilitating the psychosocial risk at this factory.This survey results only reflect the situation under the specific conditions at one particular time frame and setting. Thus, further studies with a larger sample size, improved and more specific survey methodologies for multiple settings are needed to further understand the workplace conditions as well as risks in job turnover for the factory employees.

Key words: Workplace stress; Job turnover; Mental health; Stress check

1 Introduction

The effect of mental health deterioration among workers is an important part of negative cause of work productivity (Deschenes, Desjardins, & Dussault, 2018). Workplace stress, mental issues and related drop-outs (turnovers)have long been recognized as potential risk for the management (Kitanaka, 2015).Especially, in Japan, workplace stress has broad and in-depth negative effects onto both employees and its organization (Kawada, 2016; Kawakami & Tsutsumi, 2016; Kitanaka, 2016) Based on the Japanese government research in 2017, nearly 60% of workers in Japan reported experiencing intense worry or stress related to employment and work. And over 50% of responding enterprises reported that workers increasingly faced toward mental health issues and forward actions (Tsutsumi, Inoue, & Eguchi, 2017).The organizational workplace and workers stress have been researched in many countries in recent years as well as in Japan. In fact,as a result of high job demands (Wang et al., 2016), manufacturing employees in China are facing with great workpressure (Zhang et al., 2016). Some research in China also indicated that work press can predict turnover intention(Shi & Wang, 2015), job satisfaction(Zhang et al., 2015)and proactive behavior significantly (Wang& Li, 2017), but it is necessary for in-depth workplace stress studiesto provide the recommendations at an automotive manufacturing factory in detail in China in this point of time.

This study is to investigate the workplace stress effects on worker mental health and resignation behavior at a famous factory in China. It is an automobile manufacturing company headquartered inWuhan. It currently produces a variety of foreign models and a handful of China-only products. Because of competition,turnover in this factory is much higher than before. It is estimated to reduces work performanceand increase various work-life risk with its worseningaccident rates, absenteeism, job turnovers and eventually their quality of life.

2 Research Methods

2.1 Psychological scales

Chinese version of Social Adaptation Self-evaluation Scale (SASS) and Hamilton Depression Rating Scale (Ham - D) and Beck Depression Inventory (BDI) was used for the factors analysis (stress factor, recognition, stress reaction, work satisfaction, social support, corporate culture and etc.) in the used research model. Independent variables were measured by Japanese version of Karas's Demand-Control questionnaire and Siegrist's Effort-Reward Imbalance Questionnaires. This model was consists of two components, one is psychological demands and another is task control which is defined by the expertise discretion and job position authority and autonomy. This model explains that high demand with low job control authority is negatively affect health at workplace. A confidence analysis was performed on each

* Corresponding author: Luo Fan, sailluof@126.com

factor of each scale for the total sample and Cronbach's alpha was .70 to .92 for most factors, and some values were lower in workplace environmental factors and giving up or abandonment factors.

2.2 Sample Profile

A cross-sectional survey was conducted under instructions by Human Resources section of this factory. The questionnaire was distributed to this factory workers in April 2017 using in-house electronic equipment. Privacy and ethical considerations are implementedwith management approval for this research. The number of valid responses was 1055 (914 men and 141 women) with response rate of 88.7%. The mean age is 30.33 years for men and 30.78 years for women.

As for job title and profiles, general managers were 761 males (83.3% for total males) and 134 females (95% for total females). The engineers and general practitioners were 103 males (11.3%) and 1 female (0.7%). Interim managers were 42 males (4.6%) and 6 females (4.3%). Senior management personnel were 8 males (0.9%) and no females. Education background is as follows: The number of university graduates was 450 males (49.2% for total males) and 61 females (43.3% for total females). The number of junior college graduates was 45 males (4.9%) and 3 females (2.1%). Graduate with Master's degree holders were 410 males (44.9%) and 76 females (53.9%). Junior high school graduates are for two men (0.2%) and none women. Ph.D. holders are 3 males (0.3%) and 1 female (0.7%). The technical school graduates are 4 males (0.4%) and no females.

31 employees had left this factory at June 2017 from the time point ofthis stress survey conducted in April 2017. These 31 turnover persons were 28 males with a mean age of 28.89 years and 3 females with 30.67 years old. 207 subjects (142 males, mean age of 32.54 years, 65 females with mean age 30.14 years) are randomly selected from the total of 1024 subjects (excluding 31 retirees) were compared statistically in this analysis.

The data were analyzed for the Significance Testing (t-test) with using SPSS Statistics software version 22.0 (IBM, Armonk, NY). The data were analyzed using descriptive statistics such as mean, standard deviation, standard error of mean, 95% confidence interval, percentage, and frequency. Data were fitted using two-tailed Normal fitting first. The Normality was checked using *Shapiro-Wilk W* test. The null hypothesis (*H*o) posited that the data was from the Normal distribution; a *p*-value smaller than or equal to the significance level (0.05) rejects *H*o.

2.3 Structure of the questionnaire

The used questionnaire was consisted of 111 questions in total. For each item, survey participants choose rates from 1 to 4 options between "1 for none" and "4 for very much fit and often".Scales for sources of job stress are consisted with total of 23 items. It consists of nine factors: "amount of work," "difficulty in working," "supervisor's personnel management," "sense of acceptance of evaluation," "physical workplace environment," "understanding and fulfillment of the significance of work," "work discretion," "human relations in the workplace," and "private environment." The scale on the ability to cope with stress, a stress-tolerant capacity, are consisted of a total of 41 items. The cognitive approach to the stress is two psychological factors: "positive thought" and "retrospective pessimistic thought". The behavioral approach as stress management is based on four factors: emphasis on situation improvement, emphasis on mood improvement, habitual and reflexive thoughts, and abandonment. Stress coping consists of five factors: "Emphasis on improving conditions," "Liberal and abandoned behaviors," "Emotional behaviors," and "Mood-changing behaviors," and "Consultative behaviors with others".

As for the Psychological Stress Reaction Scale, a stress response, includes 17 items with four factors: apathy, anxiety/tension, anger, and feeling unwell. Job Satisfaction Scale consists of three items. As for social support, 15 items with three factors: "supervisor support," "peer colleague support," and "family and friends support." A total of 12 items are included in the scale for organizational and corporate culture with five factors: "respect for autonomy," "teamwork," "failure is not accepted," "aiming for too high a goal," and "equal opportunities."

3 Data Analysis

3.1 Analysis on mental health

The unpaired *t*-test result for the presence or absence of a significant difference is as follows.

(1) Differences between Genders

The overall scale for sources of stress at work is $M = 2.33$ ($SD = 0.37$).There is no significant difference between genders (t (1053) =1.08, *n.s.*). For example, the stress tolerance capacity was $M = 2.59$ ($SD = 0.18$); $M = 2.58$ ($SD = 0.18$) in males and $M = 2.62$ ($SD = 0.18$) in females, between genders (t (1053) = 2.24) with significant difference at the 5% level.In addition, the "unpaired *t*-test" is

performed for gender differences. For the Sources of stress at work: "understanding of the meaning of work/feeling of fulfillment" with (t(1053)=2.80, p<.01) and "workplace relationships" (t(1053)=2.99, p<.01).　As for the stress tolerance ability was "retrospective pessimistic thinking" with (t (1053) =2.27, p<.05), "Emotional behavior" (t (1053) =2.37, p<.05) and "mood swing behavior" (t(1053)=4.65, p<.01). Stress responses included "apathy" (t(1053)=2.22, p<.05), "anxiety/tension" (t(1053)=2.08, p<.05) and "anger" (t(1053)=2.89, p<.01.　For social support, support from supervisors (t(1053)=2.39, p<.05), in the corporate culture, "equal opportunity" (t(1053)=4.49, p<.001) with a significant difference.In the next step, "one-factor analysis of variance" is conducted to determine whether there are differences in mental health conditions among employees' positions.

(2) Differences between the Groups

There was a significant difference between the groups in the sources of job stress (workload: F(3, 1051)=10.32, p<.01, job difficulty: F(3,1051)=8.88, p<.001, Understanding/fulfilling job meaning: F(3,1051)=3.15, p<.05. Then, multiple comparisons are made by Tukey's HSD method (5% significance level). "Work amount" was higher for intermediate managers than general managers, and was lowest for engineers and general managers. "Difficulty in work" indicates that intermediate managers are more likely than general managers, and general managers have the same results as engineers and general managers. There was a significant difference in stress-tolerant capacity among the groups in "positive thoughts" (F(3,1051)=2.44, p<.10) and there were significant differences among "positive thoughts," "abandoned behaviors," "mood turning behaviors," "status improvement," "mood improvement emphasis," and "habitual and reflexive thoughts." (Emphasis on Situation Improvement: F(3,1051)=4.05, p<.01, Abandoned behavior: F(3,1051)=2.99, p<.05, Mood-transforming behavior: F(3,1051) = 3.01, p<.05, Situation Improvement Focused: F(3,1051) = 3.59, p<.05, Emphasis on mood improvement: F(3,1051)=4.73, p<.01, Habitual and reflexive thinking: F(3,1051)=4.32, p<.01. Then, multiple comparisons are made by Tukey's HSD method (5% significance level). "Positive thinking" is higher in senior managers than in general managers, and "Emphasis on improvement of situation" is higher in middle managers than in general managers, and general managers are the same as engineers and general managers. On the "mood change action", engineers and general employees were higher than the intermediate managers. "Emphasis on mood improvement" is higher in senior managers than in middle managers, and intermediate managers are the same as general managers. "Habitual and reflective thoughts" are the result that senior managers are higher than engineers and general managers, and that engineers, general managers and general managers are the same. There were significant differences in stress responses between the groups in terms of "apathy," "anxiety tension," "anger," and "feeling sick." apathy: F(3,1051)=8.28, p<.001 anxious strain: F(3,1051)=3.42, p<.05, anger: F(3,1051)=3.61, p<.05, Physical distress: F(3,1051)=5.12, p<.01. Then, multiple comparisons are made by Tukey's HSD method (5% significance level). For "apathy," general managers are higher than middle managers, and for "physical discomfort," general managers are higher than engineers and general managers. There was a significant difference in job satisfaction between the groups (F(3,1051)=6.64, p<.001). Multiple comparisons by Tukey's HSD method (5% significance level) are performed. Senior managers are higher than middle managers, and middle managers are the same as general managers. For social support, there was a significant difference between the groups in "Family Friends Support" (F(3,1051)=2.97, p<.05). Then, multiple comparisons are made by Tukey's HSD method (5% significance level). The result is that engineers and general employees are higher than general managers. As for corporate culture, there are significant differences between groups in respect of autonomy and teamwork. Respect for autonomy: F(3,1051)=6.27, teamwork: F(3,1051)=6.71. Both were p<.001. Multiple comparisons by Tukey's HSD method (5% significance level) are performed. For respect for autonomy and teamwork,both technicians,and general workers are higher than general managerial officials (see Table 1).

Table 1　Mean Scores and Standard Deviation by Employee's Position and Result of One-factor Analysis of Variance

Variable　（α）	engineers andgeneral workers （n=104）	general managers （n=895）	middle managers(n=48)	senior managers(n=8)	F	multiple comparisons

3.2 Psychological analysis on leaving workers

Next, we do "unpaired *t* test" for mental health of the resigned person and the scale of each employee currently enrolled. Regarding stress sources, the incumbent is $M=2.10(SD=0.30)$, and the leaving person is $M=2.40(SD=0.44)$. There is a significant difference at the 1% level between affiliation ($t(34.26)=3.68$, $p<.01$). Regarding the stress tolerance ability, the incumbent has $M=2.56(SD=0.19)$ and the leaving person $M=2.64(SD=0.22)$. There is a significant difference at the 5% level between affiliation ($t(236)=2.34$, $p<.05$). Regarding the stress reaction, the incumbent is $M=1.77(SD=0.43)$, and the leaving worker $M=2.36(SD=0.67)$. There is a significant difference at the 0.1% level between affiliation ($t(33.71)=4.69$, $p<.001$). Regarding job satisfaction degree, $M=3.15(SD=0.44)$ for incumbent, $M=2.78 (SD=0.55)$ for leaving worker. There is a significant difference at the 0.1% level between affiliation ($t(236)=4.19$, $p<.001$). Regarding social support, the incumbent is $M=3.19(SD=0.42)$, and the leaving worker is $M=3.08(SD=0.48)$. There is no significant difference in affiliation ($t(236)=1.38$, *n.s.*). Regarding corporate culture, the incumbent is $M=2.92(SD=0.36)$, and the leaving person $M=2.85 (SD=0.33)$. There is no significant difference between affiliation ($t(236)=1.38$, *n.s.*). In order to study further in detail, perform "unpaired *t* test" for each factor. In the stress source, there was a significant difference in "difficulty of work" ($t(236)=1.75$, *n.s.*).

Furthermore, all other factors ("amount of work" ($t(35.71)=2.39$, $p<.05$), "managerial management of boss" ($t(236)=2.59$, $p<.05$), "conviction of evaluation ($t(33.92)=2.77$, $p<.01$), "physical work environment" ($t(236)=4.09$, $p<.001$), "understanding / sense of fulfillment of work" ($t(38.04)=3.88$, $p<.001$), "Working authority" ($t(236)=2.45$, $p<.05$), "workplace human relations" ($t(38.04)=3.88$, $p<.001$) "Private environment"($t(236)=2.16$, $p<.05$)) has a significant difference. In the stress tolerance ability, "positive thinking" ($t(236) = 3.75$, $p < .001$), "retrospective pessimism thinking" ($t(34.264) = 4.02$, $p < .001$), "emphasis on situation improvement" ($t(51.809) = 2.13$, $p < .05$), "habitual / reflexive thinking" ($t(236) = 2.84$, $p < .01$), "abandon thought" ($t(236) = 2.45$, $p < .05$) , "Emphasis on situation improvement" ($t(52.512) = 2.91$, $p < .01$), "give up / abandon behavior" ($t(236) = 3.09$, $p < .01$), "emotional act" ($t(236) = 3.27$, $p < .01$). for the "lethargy" ($t(34.062) = 4.76$) "Anxiety" ($t(34.174) = 4.76$) "Anger" ($t(33.152) = 4.58$) "Physical disorder" ($t(236) = 3.80$), all $p < .001$, there is a significant difference.In social support "colleague support" ($t(236) = 1.73$, $p < .10$). There is a significant tendency. But "Boss support" ($t(236) = 1.45$, *n.s.*) and "Family friends support" ($t(236) = 0.58$, *n.s.*). There was no significant difference. In corporate culture "respect for autonomy" ($t(236) = 3.08$, $p < .01$) and "team work" ($t(236) = 3.68$, $p < .001$). There are significant differences respectively (see Table 2).

4 Results and Discussion

As a result of examining the mental health status of employees according to job positions in this research, the stress sources for intermediate managers were significantly higher. And, the stress reaction of general manager, engineers and workers is significantly high. We divide the incumbent and the departure person, and correlated factors between each scale. We examined whether differences in the relevance of each scale between the leaving job and the incumbent person can be seen. Pearson's moment correlation coefficient was calculated. A weak correlation ($r=.252$) between the stressor and the stress tolerance was observed for the incumbent, but a strong correlation ($r=.705$) was observed for the departure person.

The organizational climate and the stress response are the same as in the past for the incumbent, and a negative correlation ($r=-.201$) was observed. However, there was a positive correlation ($r=.159$), although it was not significant in leaving workers.Since this result shows the same tendency as that shown in the model of the previous study, the content validity is considered to have been shown (see Table 3).

In addition, there was a significant increase in the sources of stress, job satisfaction and the stress responses in the comparison of the mental health for the resigned and current employees. Especially, the stress tolerance capacity is considerably low. It is anticipated that the stress relaxation is also difficult in this condition by their self-help (Byron et al., 2015). And it is assumed that mental health had already deteriorated before leaving work. Since this research is limited to the first step analysis in terms of statistical analysis with t-test approach, it is necessary to take further in-depth research to the cause of the stress related disorders for the whole employee in the future. In this survey we estimate the existence of non-clinical depression. From recent epidemiological studies in Japan, the economic loss of mild depression is large and future risks can not be ignored. This is also the same at the enterprise level, and the importance of intervention is discussed for avoidance of that. However, while mortality is treated as

a healthy person in mental health, it tends to be distant from the existing private service industry. As a so-called gray zone, the opportunity for service users to receive correspondence based on evidence was not sufficient.

In the future it is important for us to explore the possibility of promoting intervention mental health services for depressive employees by introducing stress releasing program. This psychological survey showed valuable psychological data results in considering those countermeasures.   It is also important for management to take effective stress prevention measures (Frone, 2018; Lanza, Roysircar, & Rodgers, 2018; Schulte-Korne, 2017) and lower the workplace stress among the employees to retain good work-life status (Turk, Davas, Tanik, & Montgomery, 2014; Wada et al., 2013) and to prevent unnecessary resignation from the employment. In Japan, there are predictions that psychological pressure and departure due to depressed state are often included in the "Other" category and "To find jobs of better conditions" in many cases. However, the empirical research has hardly any academic achievement due to strong law protecting personal information. For this reason, this research is a valuable opportunity to verify psychological factors in leaving workers by stress data.

5 Conclusion

Workplace stress is a common problem with broad effects in workers life (Stasila-Sieradzka, Chudzicka-Czupala, Grabowski, & Dobrowolska, 2018). So it is important to gain a better understanding of work-related stress and its effects on employee job turnover.

Based on the labor force survey announced in May 2018 by the Statistics Bureau of the Ministry of Internal Affairs and Communications of Japan, the survey was conducted on the trends by reasons for job separation for the previous job during the past 6 years from 2012 to 2017. In this survey, the total number of unemployed who left off was 2.5 million in 2012. This has declined to 1.35 million in 2017. Next, when looking at the share in terms of the reasons for the job separation reasons, except for "others", "the year of retirement or expiration of employment contracts" was the largest at 17% in 2012. However in comparison in 2017, "to find jobs with better conditions" was 13% in 2012, but in 2017 it is the largest in 19%. Reasons such as "for corporate bankruptcy / business closure", "due to personnel sorting and recommendation retirement", "due to business slowdown and concern about the future" have decreased in the past seven years. "Because of the expiration of retirement age or employment contract" is decreasing in the total number, but it remains unchanged in proportion, "for marriage / childbirth / nursing" "for nursing care and nursing" "for domestic affairs / school / health reasons" "others" Although the number of people is flat, the ratio tends to decrease. Surveys on reasons for job separation by the government are being implemented as such stated, but statistical surveys taking into consideration psychological aspects are rare in Japan.

This paper providedan entry stage of statisticalanalyses on workplace stressors and their effects on the job turnover at afactory. The factors among perceived stress sources, tolerance ability, stress reaction, job satisfaction had the effect on the level of job turnover. The findings of this study helped to establish a baseline to measure the work mental health condition and corresponding job turnover within the organization studied. This may assist management in identifying ways to improve employee job turnover. Firstly,according to the findings, the stress sources for intermediate managers were significantly higher than other job positions. Therefore, it is necessary to focus on intermediate managers and pay close attention to them. Secondly, the results show that the sources of stress, job satisfaction and the stress responses will increase before employeeturnover. Meanwhile, the stress tolerance capacity is considerably low, however they cannot control it by themselves. Thus, when the increases of the sources of stress are found, job satisfaction and the stress responses, intervention strategies should be adopted to decrease them, so as to prevent them from turnover.

Thus, it is recommended to further verify the findings of this study in real situations, and continue to monitor in longitudinal studies. In addition, increased sample size are needed to further elucidate the predictors for job turnover. This was an early stage study due to such limitations, however, it serves a baseline to measure the working stress and its effect at this particular setting under study.

As recommendations for the workplace stress and risk issues, Big Data and AI utilization on worker health management are currently being planned by researcher teams in Japan and China. E-Learning based on psychological cognitive therapy approach using the Internet is being regarded promising and academic papers were published by the authors. Based on the future continuous data sampling from this-time used automotive manufacturing factory, we plan to make academic paper on this application and results in the future.

Abstract: Resilience mechanism is a paradigm for organizational as well as employees' wellbeing. The purpose of this investigation is an attempt to estimate how organizational engagement climate impacts, directly and indirectly, employees' resilience. Based on the questionnaires survey on Ready-made Garment in Bangladesh, this empirical study, via structural equation modeling, revealed that all the predictor variables significantly influence the endogenous variables. In addition, it is observed that employee engagement partially mediates the relationship between organizational engagement climate and employee resilience. Usage of cross-sectional data limits the generalization of the findings. Managerial implication and further research directions have also been discussed.
Key words: Employee resilience; Employee engagement; Engagement climate; Ready-made garments

1 Introduction

Today's organizations need to become progressively polygonal to keep pace with the challenging environments to reap the sustainable objectives. To endure and compete successfully in a lively environment, organizations require preemptive human resources (Majeed, 2011). Keeping these exclusive resources aligned with innovations, firms must look for competitive employees who can keep them abreast of any change in the external dynamics for making the organizations resilient. Perceived organizational supports, in the sense of prevailing engagement climate, occupy a significant role to substantiate the employee engagement (EE). Engagement climate persists and nurses the engaged employees which make them resilient (Zhong et al., 2016).   The definition of employee resilience builds on the definition of organizational resilience (OR). For the sake of generalization and operationalization, this research uses the definition of resilience as "the maintenance of positive adjustment under challenging conditions" (Sutcliffe and Vogus, 2003). To address this, recently an emergent curiosity is observed in employees' resilience (ER) in the organizational context and its contribution to resilient organization or organizational performance. Therefore, the organizational climate remains a fundamental construct which is an important determinant of attitudinal, behavioral, and performance-related outcomes. Schneider (Schneider, 2000) argued that climate is constituted of employees' perceptions of the events, practices, and the kinds of behaviors that get rewarded and supported in an organizational context (Schneider, 1975). Hence, the purpose of this study is to investigate the effect of organizational engagement climate (OEC) on ER in small and medium-sized companies, wherein EE is proposed as a mediator.

2 Theoretical Foundations and Hypothesis Formulation

2.1 Impact of organizational engagement climate on employee resilience

Over the years, the value of a supportive organizational climate has been recognized. There is a need for better understanding of its association with ER. Extrapolating from existing definitions in the engagement literature, Albrecht (Albrecht, 2014) demarcated OEC as collective perceptions about the energy and involvement keenly focused by employees toward the achievement of organizational goals. Kuntz et al. (Kuntz et al., 2016) conceptualized ER in an endeavor to focus on the realistic inquiry of resilience away from inner pointers of coping with strain. Extant literature presents that highly resilient individuals have better coping and adaptive capabilities when faced with hardship, such as work-related disturbance which is strongly related to OEC (Schneider and Reichers, 1983). However, as previously noted, research on the antecedents of organizational climate and their influences on ER are limited and, hence, further research is need. In view of this review, the hypothesis below was formulated:

H1. There is a significant association between organizational engagement climate and employee resilience

2.2 Influence of organizational engagement climate on employee engagement

OEC is one of the most significant determinants of individual and group attitudes and behaviors in institutions (Garcia‐Garcia et al., 2011). To date the definition of engagement is not universally agreed, but most refer to Kahn (Kahn, 1990) definition, which denotes that EE as "the connecting of organization members' selves to their work roles". Studies have indicated that employees, who are engaged with their work, play a vital role in establishing an excellent and effective work performance (Eldor and Harpaz, 2016). Moreover, the superiority of emotional incentives over tangible ones is perceived among engaged employees, as opposed to satisfied or involved employees (Eldor and Harpaz, 2016). Following that, OEC is likely to greatly affect　employee work engagement (Albrecht et al., 2018). It would increase trust between employees and the organizational management, and it promotes their engagement to their organization and work. The relationship between climate and employee engagement is based on (Blau, 2017) social exchange theory, and the equity theory. Therefore, EE has emerged as a significant concept within the field of EEC. In this regard, in order to bridge this gap, we hypothesize:

H2. Organizational engagement climate is positively associated with employee engagement

2.3 Relationship between employee engagement and employee resilience

A wide range of studies have shown EE as a significant resource pool which helps individuals to cope up with the changes experienced in life. In line with the ecological perspective , employee resilience can be enabled by the organization and is defined as "employee capability, facilitated and supported by the organization, to utilize resources to continually adapt and flourish at work, even when faced with challenging circumstances" (Kuntz et al., 2016). Xanthopoulou et al. (Xanthopoulou et al., 2008) analyzed the role of self-efficacy, organization based self-esteem and positivity as individual personal resources in prediction of EE. Following the job demand-resource (JD-R) model, it has been argued that engaged employees are better performers than non-engaged employees because engaged employees are more capable to cope up with the changing conditions in organization by using their personal resources, which empower them to effectively control their workplace environment (Bakker and Demerouti, 2008). Therefore, we propose the following hypothesis:

H3. Employee engagement is positively associated with employee resilience

This above discussion explores that OEC has direct impact on ER (Schneider, 1975, Schneider and Reichers, 1983). It is also observed that OEC influences the EE (Albrecht et al., 2018) and, in effect, EE stimulates to the development of resilient employee (Gupta and Sharma, 2018). Thus it is revealed that OEC not only directly influences the ER but also indirectly drives the ER through the indirect influence of EE. Therefore, we propose as follows:

H4. Employee engagement mediates the relationship between organizational engagement climate and employee resilience

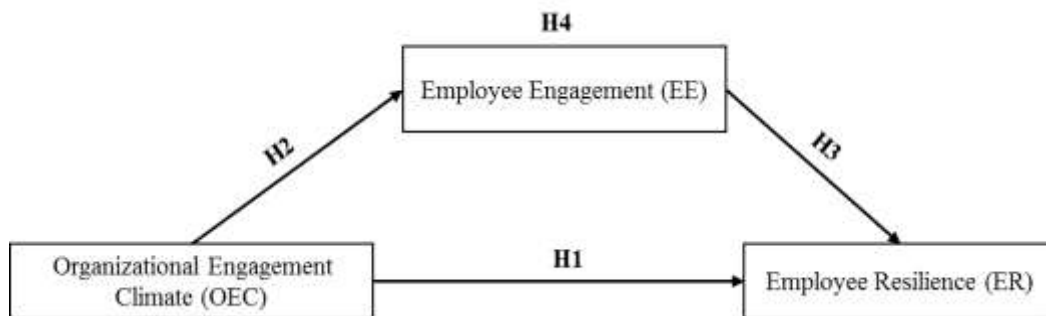
To mirror a clear demonstration of the current investigation, the researchers developed a conceptual framework (Figure 1) based on insights gained from the earlier literature review research.


Figure 1　Conceptual Research Framework

3 Research Methods and Data Collection Approach
3.1 Respondents' demographic characteristics

Simple random sampling method has been used which appears to be more appropriate for the generalization of the findings and drawing any inference on the causality on the result. Self-administered questionnaires were sent to RMGs using random sampling technique in the capital City of Dhaka, Bangladesh.

Table 1 Respondents' demographic profile (N=258)

Variables	Categories	Frequency	%	Variables	Categories	Frequency	%
Gender	Male	213	82.6	**Education**	Master	93	36.0
	Female	45	17.4		Bachelor and Others	165	64.0
Age	Below 35 Years	131	50.7	**Tenure**	Below 10 Years	147	57.0
	Above 35 Years	127	49.3		Above 10 Years	111	43.0

Out of 258 respondents 82.6 percent were male and the balance 17.4 percent were female. Their age's group consists of 50.7 and 49.3 percent belonging to above 18 and 35 years respectively. Respondents' educational profile shows that 36.0 percent, and 28.7 percent have completed their master, and others, i.e. doctorate or diploma certificate. Finally, the majority of the respondents' job experience reports that 57.0 and 43.0 percent fitting to above 5 and 10 years.

3.2 Survey instruments

The survey instruments, such as employee resilience (Näswall et al., 2015), employee engagement (Schaufeli, 2006) and and organizational engagement climate (Albrecht, 2014), were adopted from prior studies with the obligatory changes made to them for making it respondents' friendly in the given context, Items in a measure were arranged on a 5-point Likert scale from 1 (strongly agree) to 5 (strongly disagree). Microsoft Excel 2016 was used for the cleansing of the data and SmartPLS version-2 and IBM SPSS version-23 software packages were used for producing the results.

4 Models Evaluation

4.1 Measurement model evaluation

Table 1 reports that all constructs pass through the validity tests. Discriminant validity analysis (Table 1) exhibits a very good result which shows that the square root of the average variance extracted (AVE) of each construct is higher than the construct's highest correlation with any other construct (Hair Jr et al., 2016). Table 1 and figure 2 delineate that the factor loadings (all > 0.50), average variance extracted (AVE> 0.50) and composite reliability (>0.851) are within the rule of thumb (Hair Jr et al., 2016). Therefore, both validity and reliability analyses suggest that these constructs are valid and reliable for further advance.

Table 1 Latent Variables Correlation Matrix for Discriminant Validity Testing

	AVE	CR	CA	1	2	3	4	5	6	7	8
1. Age	-	-	-	1							
2. Gender	-	-	-	-.102	1						
3.Education	-	-	-	.144*	.051	1					
4. Firms' Size	-	-	-	.276**	-.219**	.082	1				
5. Tenure	-	-	-	.838**	-.105	.241**	.318**	1			
6. EE	0.564	0.901	0.872	-.091	-.061	-.092	-.164**	-.164**	**.751**		
7. ER	0.534	0.851	0.786	-.063	-.046	.033	-.109	-.109	0.325**	**.731**	
8. OEC	0.634	0.896	0.856	.034	.072	.096	-.029	-.029	0.287**	0.309**	**.796**
Mean	-	-	-	2.589	1.174	1.938	2.419	2.5	3.825	3.98	3.971
SD	-	-	-	1.052	0.38	0.806	0.781	1.223	0.549	0.51	0.619

**. Correlation is significant at the 0.01 level (2-tailed); and *. Correlation is significant at the 0.05 level (2-tailed).
AVE. Average Variance Extracted, CR. Composite Reliability, CA. Cronbach's Alpha

4.2 Structural (Path) Model

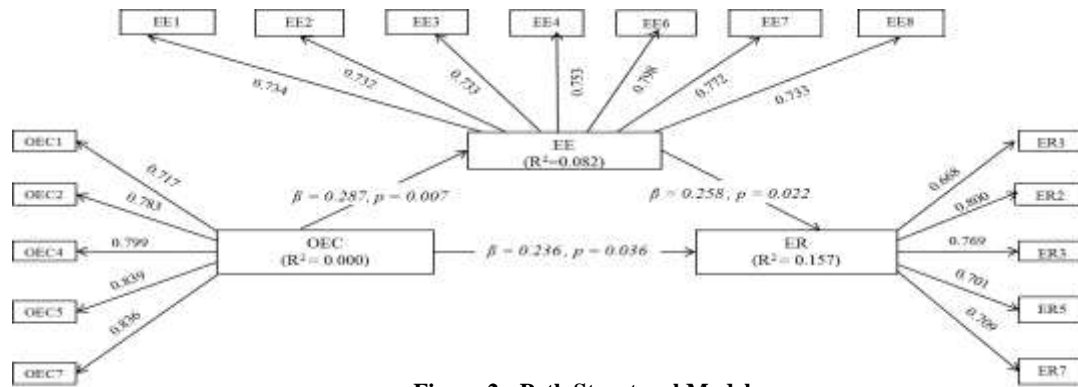
Standardized coefficient (β), percentage of variance explained (R^2), and significance levels of the path model relationships is demonstrated in figure 2 Path coefficients (βs) are above 0.10 which is above the minimum threshold. Findings have shown that standardized coefficients (βs) of OEC→EE is 0.287 (p<.01), OEC→ER is 0.236 (p<.05), and EE→ER is 0.258 (p<.05), which are found significant at different levels. As a matter of fact, OEC, and EE are describing 15.70% variance (R^2) in ER while OEC explains 8.2% variance (R^2) in EE.


Figure 2   Path Structural Model

5 Results and Discussion

The following table 2 represents the findings in the structural model. In H1, we hypothesize that organizational engagement climate is significantly linked with the employees' resilience. The estimated result (β=0.236, p<0.05) supported the hypothesis. This result is found consistent with the findings of Schneider and Reichers (Schneider and Reichers, 1983).The H2 reported that the organizational engagement climate reserves a significant influence on employees' engagement. In line with the hypothesis, the calculated results (β=0.229, p<0.01) strengthen the proposition. Prior research results also supported the studied findings (Albrecht et al., 2018). The H3 proposes that employees' engagement significantly predicts employees' resilience. The observed results unearthed that employees' engagement has a significant influence, β =0.258; p<0.05, on employees' resilience. The current findings is also found similar with the rest of the findings worldwide (Gupta and Sharma, 2018).

Table 2   Estimates in the Structured Path Relationships

	Paths	Beta-Coefficient	Standard Error	T Statistics	p-Value	Results
H1	OEC -> ER	0.236	0.1114	2.111	0.036	Supported
H2	OEC -> EE	0.287	0.103	2.786	0.006	Supported
H3	EE -> ER	0.258	0.1093	2.358	0.019	Supported

The mediating effect is measured by the ratio of indirect effect of the constructs with direct effect of the construct. For this purpose, both indirect and direct effects of OEC and ER have been computed. The table 3 estimated impact of OEC on ER before and after using mediator variable EE. The direct effect (c) before running the mediating variable (EE) was significant. After linking through mediator variable, the direct effect (c') is still significant. Thus we checked the variance account for (VAF) and the estimates showed that there is a partial mediation effect of using EE since VAF scores are more than 0.20 (Hair Jr et al., 2014). Therefore, H4 is supported to the fact that EE partially mediates the hypothesized relationship. The influence of the indirect effect of EE is also supported by the previous studies (Gupta and Sharma, 2018, Truss et al., 2013).

Table 3   Estimates of the Mediating Effect

	Path	β	Standard error	t	p	IE*	TE**	VAF
	OEC→ER (c)	0.315	0.104	3.029	0.003			
H4	OEC→EE (a)	0.287	0.103	2.786	0.006	0.074	0.310	0.239[FM]
	EE→ER (b)	0.258	0.109	2.358	0.019			
	OEC→ER (c')	0.236	0.111	2.111	0.036			

IE (Indirect effect) = a*b, TE (Total effect) = c' + indirect effect, VAF=Indirect effect/Total effect

6 Conclusion

This study, firstly, aims at finding the potential impact of OEC and EE on ER of the RMGs in Bangladesh. It has been proved that all of them have a significantly influence on ER. Secondly, OEC has influence on EE level at the work place. When employees find harmonious relationship with their boss in the organization they feel encouragement to do more work for organization. Additionally,

OEC have significant positive influence on EE. Moreover, EE partially mediates the relationship of OEC and ER. Thus, the findings of this study are expected to work as guidance for the policy makers and practitioners to enhance the employee resilience of the RMGs industries in Bangladesh. The current study uses cross-sectional data with a small number of respondents which limits the causal inference. The respondents from Dhaka city alone also prevent generalization of the findings. Further research might be benefited with relatively large sample size from longitudinal survey from different geographical arena.

Inclusive Human Resource Practice and Innovative Behavior: The Moderating Effect of Homesickness and Emotional Exhaustion

Lu Qian, Zhao Fuqiang
School of Management, Wuhan University of Technology, Wuhan, P.R. China, 430070
(E-mail: 1198246741@qq.com, zhaofq@whut.edu.cn)

Abstract: Based on the theory of resource conservation, this study considers that inclusive human resource practices have an impact on individual innovation behavior, which is moderated by homesickness. In addition, this study clarifies that emotional exhaustion can exacerbate the destructive effects of homesickness. By collecting 292 sample data, the study found that inclusive human resource practices have a positive impact on individual innovation behavior, and homesickness moderates the impact of inclusive human resource practices on innovation behavior. When the level of homesickness is high, the impact of inclusive human resource practices on innovation behavior will be weakened. Emotional exhaustion moderates the moderating effect of homesickness. When the level of emotional exhaustion is high, the weakening effect of homesickness will be stronger. Based on this, this study provides theoretical and practical reference for the study of inclusive human resource practice, and further enriches the homesickness literature.
Key words: Inclusive human resource practice (I-HRP); Homesickness; Emotional exhaustion (EE); Innovative behavior (IB)

1 Introduction

The complexity of the external environment and organizational competition and the development of science and technology make more and more practitioners and managers realize the importance of innovation. Innovation has become the motive force and source of the survival and development of the enterprise. A large number of studies show that innovation is conducive to the improvement of organizational performance, while organizational innovation depends on individual innovation behavior (Gong et al., 2013). Therefore, how to effectively motivate the individual's innovative behavior is an important question to think about in the organization management, especially for the employees of different backgrounds, cultures, nationalities, sexes, regions and so on, in the context of globalization.

Formal organizational support influences individual innovation behavior. The research shows that human resource practice is conducive to promoting individual innovation (Chang et al., 2014). However, the previous research on human resources practice emphasizes the universality of the employees, and the past diversification management emphasizes the equal treatment of the differentiated employees. This management practice and management method could not solve the contradictions and conflicts caused by diversification (Nishii, 2013). In order to make diversity employees feel fair, while develop the potential of diversified employees, managers put forward inclusive management which has a positive impact on employees' behaviors, attitudes and performance (Carmeli et al., 2010). Previous studies on the impact of inclusive management on individuals mainly focus on the role of inclusive leadership, and little knowledge about how I-HRPs affect individual behavior (Yinhua G U, Tao Q, Yang F, et al., 2017). Based on this, this study aims to explore the impact of I-HRPs on individual innovation behavior and its boundary conditions.

There are more and more employees coexist with different backgrounds, cultures, nationalities, gender and regions who face with homesickness. In work, homesickness and negative emotions may consume employees' attention, emotion and energy. Based on the conservation of resource theory, if the resources of one area are exhausted (attention, emotion, energy), it may make it impossible to work in the best way in another field, so homesickness may reduce individual performance (ten Brummelhuis, Bakker A B, 2012). Therefore, in this study, we examined whether homesickness can disrupt the impact of I-HRPs on individual innovation behavior. Besides, due to emotional exhaustion could affect homesickness, we further explore whether emotional exhaustion can affect the weakening effect of homesickness.

2 Hypotheses Development

2.1 I-HRP and innovation behavior

The individual's innovation behavior refers to the production, promotion and practice of creative

ideas, which individuals can participate in innovation activities at any stage (Yuan and Woodman, 2010). Based on the conservation of resource theory, individuals not only try to maintain and protect their existing resources, but also try their best to acquire and develop new resources. I-HRPs, such as diversified recruitment and selection, diversified training and development, can increase the stock of employees' resources and bring diversified knowledge and skills to employees (Gardner et al., 2011). Research shows that diversification of knowledge communication can effectively promote innovation behavior (Milliken F J, Martins L, 1996). The full flow of knowledge among members is easy to form informal brainstorming, resulting in many creative ideas and inspiring employees' innovative behavior. In addition, inclusion of errors is a specific implication of inclusive human resources practice, and tolerance of innovation failure promotes individual innovation motivation (Tang et al., 2015). Based on this, we hypothesize:

Hypothesis 1: I-HRP is positive related to individual innovation behavior.

2.2 Homesickness as a moderator

For the variety of employees, there are great differences between their colleagues and themselves, which makes it easier for employees to feel lonely and insecure e (Du D, Derks D, Bakker A B, et al., 2018). In order to eliminate these negative emotions, individuals consume considerable mental resources, such as time, energy, and emotions. The individual of homesickness tends to see the negative side of the work so that it lacks the physical strength to work and reduces the effective use of social resources in the field of work (Shaffer et al., 2012). It may hinder the benefit of the staff from the social support, thus reducing the effect of the I-HRP on the individual innovation behavior (Nohe et al., 2014). Therefore, we hypothesize:

Hypothesis 2: Homesickness moderates the relationship between I-HRP and individual innovation behavior. When the level of homesickness is high, the impact of I-HRPs on individual innovation behavior is weaker.

2.3 Emotional exhaustionas a moderator

Emotional exhaustion refers to the fatigue state caused by excessive use of psychological and emotional resources(Shantz A, Arevshatian L, Alfes K, et al., 2016), which is a result of stress reaction caused by stressors in the workplace (Maslach et al., 2001). Emotional exhaustion is the state of exhaustion of emotional and physiological resources, which will reduce employees' investment in work and reduce employees' work performance (Aryee et al., 2008). According to the conservation of resource theory, when the individual is in the state of emotional exhaustion, the individual takes a defensive state to reduce the loss of resources. That is, the individual could not have enough resources to manage the consumption of psychological resources brought by the homesickness, which may aggravate the individual's homesickness and further weak the role of inclusive human resources practice in promoting individual innovation behavior (Hobfoll, 1989). Therefore, we hypothesize:

Hypothesis 3: Emotional exhaustion moderates the weakening effect of homesickness on the relationship between I-HRP and individual innovative behavior.
Figure 1   Theoretical Hypothesis Model

3 Data and Results

3.1 Data sample

We used questionnaires to collect data and distributed 367 questionnaires. It recovered 315 questionnaires, of which removing 23 invalid questionnaires and the remaining 292 were valid.Among the respondents, 61.0% were male and 39.0% were female; 15.4% were younger than 25, 32.5% were 26-35, 50.7% were 36-55, 1.4% were above 55; 75.0% were married, 25.0 % unmarried.

3.2 Measures

Inclusive human resources practices. Referring to studies by Nishii L.H. (2013), and Tang N (2015), based on expert opinion and survey respondents' feedback, we developed a 22-item scale. We used 207 sample data for exploratory factor analysis. Removing two items with a load less than 0.5, it formed a

20-item 5-dimension measurement scale. We also carried out confirmatory factor analysis, and the five-factor model fit index was the following: χ^2 /df =3.475, NFI = 0.917, CFI = 0.939, IFI = 0.939, TLI = 0.927, RMSEA = 0.075. In this study, we used 5-point score to measured variables. The Cronbach 's alpha value of the scale is 0.944.

Homesickness. We adapted the 20-item scale of Stroebe M, Vliet T V, Hewstone M, et al (2002). The Cronbach 's alpha value of the scale is 0.913.

Emotional exhaustion. We adapted the 9-item scale of Maslach C, Jackson S E. (1981). The Cronbach 's alpha value of the scale is 0.939.

Innovative behavior. We adapted the 6-item scale of G. S S, Bruce R A (1994). The Cronbach 's alpha value of the scale is 0.944.

3.3 Results

From the descriptive statistical analysis results in Table 1, we could see that I-HRP and individual innovation behavior have significant correlation (r= 0.30, $p < 0.01$).

Table 1   Descriptive Statistical Analysis Results

Variables	M	SD	1	2	3	4	5	6	7
1.Gender	1.39	.489	1						
2. Age	2.38	.757	-.337**	1					
3.Marriage	1.25	.434	.186**	-.594**	1				
4.I-HRP	3.50	.748	.061	-.114	.031	1			
5.Homesickness	3.03	.559	-.090	.018	.026	.026	1		
6.EE	3.68	.753	-.055	-.059	.100	-.187**	.375**	1	
7.IB	3.87	.693	-.134*	.093	-.058	.301**	.129*	-.175**	1

In this study, we used SPSS 22 to do regression test, the result shown in Table 1. According to model 2, the inclusive human resources practice is significantly positive correlated with individual innovative behavior (β = 0.319, $p < 0.001$), so hypothesis 1 was supported. From model 3, the interaction of I-HRP and homesickness has a significant negative impact on individual innovation behavior (β = -0.133, $p < 0.05$), that is, homesickness moderates the role of I-HRP in promoting individual innovation behavior, and results support hypothesis 2. The simple slope test showed in Figure 1. From model 4, the interaction of I-HRP, homesickness and emotional exhaustion has a significant correlation with innovation behavior (β = 0.273, $p < 0.001$),that is, emotional exhaustion moderates the weakening effect of homesickness.In short, results support hypothesis 3.

Table 2   Regression Analysis Results

Variables	Innovative behavior			
	Model 1	Model 2	Model 3	Model 4
1.Gender	-.116	-.124*	-.115*	-.102

Figure 2   The Interaction Effect of I-HRP and Homesickness on Individual Innovation Behavior

4 Conclusion

This study explores the impact of I-HRPs on innovative behavior and its boundary conditions. It found that I-HRP has a significant positive impact on innovation behavior. This study also proves the moderating effect of homesickness on the relationship between I-HRP and individual innovation behavior. When the level of homesickness is high, the effect of I-HRP on individual innovation behavior is weaker. Besides, this study further found that emotional exhaustion moderates the weakening effect of homesickness. When the level of emotional exhaustion is high, homesickness plays a more powerful role.

Although this research enriches the literature of I-HRP and individual creativity, there are still some shortcomings. First, the data of this study are cross-sectional data, which could not explain causality. Future research can further explain it by longitudinal research. Second, this study uses self - reported data to collect data. There may be a common method deviation problem. Future research can collect data in a variety of ways to reduce the problem of common method deviation. Finally, this study only discusses the boundary conditions of inclusive human resources practice on individual innovation behavior, and future research can further explore its internal mechanism.

Cross-lagged Regression Analysis of Work Engagement and Turnover Intention

Lv Ying, Xie Baoguo
School of Management, Wuhan University of Technology, Wuhan, P.R. China, 430070
(E-mail: 1822348278@qq.com, xiebaoguo@foxmail.com)

Abstract: This study takes 893 employees of a large state-owned communication company as the study sample. Based on the perspective of social exchange theory and conservation of resource (COR), it is suggested that there may be mutual prediction between work engagement and turnover intention. Using the cross-lag regression analysis method, this study draws the conclusion that the work engagement can negatively predict the turnover intention, and the turnover intention can also negatively predict the work engagement. It has practical guiding significance for increasing employee input and reducing turnover intention.

Key words: Work engagement; Turnover intention; Social exchange theory; Conservation of resource

1 Introduction

Work engagement is a kind of behavior and manner that the individual displays in the work which gathers vigor, dedication and concentration, and it is the positive response of the staff to the organization (Schaufeli & Bakker, 2004). By contrast, not engaging in work can mean negative feedback to the organization.A large number of previous studies have shown that negative attitude towards the organization is an important variable leading to turnover intention (Zhao, Liu, & Zhang, 2003; Li & Ling, 2007). Therefore, it can be speculated that employees with lowwork engagement may have higher turnover intention than those with high work engagement.From the perspective of empirical research, some studies do prove that work engagement can predict turnover intention negatively (Schaufeli & Bakker, 2004;Saks, 2006; Plooy & Roodt, 2010; Alarcon & Edwards, 2011; Bhatnagar, 2012; Bothma & Roodt, 2012; Takawira, 2014).Unfortunately, these studies are generally deficient in the following two aspects.First, the lack of theoretical support.As pointed out by Schaufeli (Schaufeli,2004), work engagement is essentially a positive psychological response to work, its effectiveness depends to a great extent on the possession and preservation of individual working resources. Therefore, the theory of conservation of resources (COR) is an important theoretical basis for explaining the mechanism of work engagement.In view of this, this paper argues that COR theory can effectively discuss the negative predictive effect of work engagement on turnover intention. From the point of view of gain spiral and loss spiral, through the positive and perfect response to work (Schaufeli, 2002) employees can not only protect their existing resources from loss, but also create more resources. When employees continue to use the resources in the personal resource pool to create new resources, bring greater resource growth, and enter into the value-added spiral state, employees will be full of hope for the future. Greater enjoyment of the satisfaction of this sense of self-efficacy resulting from work engagement, and therefore less likely to result in a tendency to quit (Hobfoll, 1989; Schaufeli & Bakker, 2004). What's more, from the stress perspective of COR theory, when employees are in the value-added spiral state, they already have a lot of resources, and there is a greater possibility to create more resources. Once separated, these resources may suffer losses or even disappear. When an individual assesses the risk of a significant loss of resources, it creates a sense of stress and unease, and then tries to avoid it (Hobfoll, 1989). Apart from that, adopt cross-sectional research and design.Up to now, domestic and foreign studies on the negative prediction of turnover intention of work engagement generally use cross-sectional research design (Schaufeli & Bakker, 2004; Saks, 2006), but due to cross-sectional research cannot accurately derive the causal relationship between variables. Previous studies are not sufficient to confirm that work engagement is a predictor of turnover intention.

In real life, however, there is a common phenomenon that employees with a tendency to quit tend to think that they will leave the organization sooner or later, and there is no need to invest a lot of time and energy in their work.Their specific performance in the daily work is to take the attitude of

coping with the work, and deliberately reduce the work engagement.Therefore, there may be another mechanism between work engagement and turnover intention, that is, turnover intention predicts work engagement. And on the basis of the social exchange theory, the relationship between employees and organizations is essentially a kind of social exchange relationship (Blau, 1986).In a good social exchange relationship, the employees who work strenuously often get the reward feedback from the organization, and thus produce a sense of obligation to repay the organization, and then maintain or improve the current work engagement status. Create better performance for the organization (Li & Mei, 2012). On the contrary, when the employee has the idea of leaving the organization, it shows that his social exchange relationship with the organization has been destroyed, and the he no longer considers himself to be the beneficiary of the exchange process. Naturally, there is no obligation to return to the organization, let alone work to help the organization to create more value (Li & Tang, 2010). In addition, in the satisfaction of the sense of reward, because the previous work commitment did not allow employees to obtain the expected organizational reward, it has led to a lower sense of return. In subsequent jobs, employees balance their social exchange with the organization by reducing their work engagement and make it fair (Blau, 1986). If the employee has a turnover intention in this process, it is very likely that the employee has not received the expected reward response in the process of social exchange with the organization, resulting in the idea of terminating the social exchange with the organization (Blau, 1986). According to the reciprocity principle of social exchange theory, when organizations do not provide employees with the expected "favor", employees will not generate a sense of obligation to return to the organization, and will not engage in work to help the organization grow better (Su Zhongxing, Yang Jiaozheng 2016).All of the above studies indicate that turnover intention may have the same predictive effect on work engagement, but previous studies have been lack of empirical test on this perspective.

In conclusion, it is necessary to further explore the causal relationship between work engagement and turnover intention by adopting longitudinal cross-lag research design.

2 Method
2.1 The sample of study
In this study, 1115 employees were randomly selected from a large state-owned communications company with the help of the human resources manager of the company.Prior to the formal investigation, 1,115 target employees were invited by internal mail to explain that the purpose of the questionnaire was academic research only, and promised to keep the results confidential.Then we provide the personal network test account number and password for the employees who are finally confirmed to participate in the investigation, the employee will log in and fill in the form.Two questionnaires were conducted in this study, with an interval of 8 months.A total of 1115 questionnaires were sent out in T1 time, 1017 valid questionnaires were collected, and 8 employees were lost at T2 due to post changes and separations (the wastage rate was 0.79 and 1009). After eliminating the questions with missing answers and regular answers, 893 subjects filled in the valid questionnaires after T1 and T2 were filled out. 80.09% of them were involved in the questionnaire.For the team supervisors, 28.44% were male and 71.66% were female. 54.65% were married and 45.35% were unmarried.As for the team members, 20.27% was college degree, 51.18% was undergraduate degree, master degree or above is 20.17%.Their average age was 29.49 years old (SD = 4.31), the average organizational tenure was 6.11 years (SD = 3.86).

2.2 Measurement
Work engagement. The UWES-9 questionnaire was used to measure the level of work engagement of employees (Schaufeli et al., 2006). The questionnaire contained three dimensions, including vigor, dedication and absorption. There were nine entries in three dimensions. Sample items are "When I get up in the morning, I want to go to work."(Vigor), "I am proud of what I am doing." (Dedication), "I feel happy when I am immersed in my work." (Absorption). The participants were asked to respond on a 7-point Likert scale ranging from 0 (not at all true of me) to 6 (totally true of me).The final result was obtained by taking the average of the nine items, and the final score ranged from 0 to 6. The higher the score, the higher the level of work engagement. Relevant studies have shown that UWES-9 has a good inter-scorer's reliability in the measurement of job input of Chinese knowledge workers (Li, 2011). In this study, the internal consistency α

values of T1 vigor, dedication and absorption subscale were 0.797, 0.940 and 0.849, respectively, and the internal consistency α values of the total scale were 0.938. The internal consistency α values of T2 vigor, dedication and absorption subscale were 0.812, 0.933 and 0.829, respectively, and the internal consistency α values of the total scale were 0.936.

Turnover intention.This study uses a four-item questionnaire of turnover intention used by Chen & Francesco.Sample items is "I often want to stop my present job."The participants were asked to respond on a 7-point Likert scale ranging from 1 (not at all true of me) to 7 (totally true of me).The final score ranges from 1 to 7. The higher the score, the higher the turnover intention.In this study, the internal consistency α values of T1 and T2 were 0.782 and 0.789, respectively.

3 Results
3.1 Descriptive statistics on work engagement and turnover intention

As shown in Table 1, the work engagement of the sample in the same year is significantly correlated with the turnover intention. The correlation coefficients of the two persons at T1 and T2 are -0.58 and -0.59.T1 respectively.

Table 1　Descriptive Statistics and Correlation Between Total Samples

	T1 Work Engagement	T2Work Engagement	T1turnover intention	T2turnover intention
M±SD	3.75±1.16	3.79±1.14	2.48±0.81	2.52±0.85
1. T1 Work Engagement	1			
2. T2 Work Engagement	0.51**	1		
3. T1turnover intention	-0.58**	-0.37**	1	
4. T2turnover intention	-0.44**	-0.59**	0.51**	1

Note: * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$, similarly hereinafter.

3.2 Cross-lagged Regression Analysis of Work Engagement and Turnover Intention

In order to further explore the bidirectional prediction effect of work engagement and turnover intention, this study takes T1 and T2 as pre-and post-test time points, collects data at intervals of 8 months, and carries out cross-lag regression analysis on the results of pre-and post-test.The final result is shown in figure 1.At T1 and T2, both work engagement and turnover intention were stable to an advanced degree, $\beta=0.51$ and p less than 0.001.There was high negative correlation between job commitment and turnover intention at T1 and T2 (-0.58, -0.59). The above results show that the stability correlation and synchronization correlation of this study are consistent and meet the basic assumptions of cross-hysteresis analysis.

Assuming that H1 infers that work engagement can predict turnover intention negatively, according to the result of regression analysis shown in figure 1, work engagement can predict turnover intention at T2 significantly ($\beta = -0.44$, $p < 0.001$).Assuming that H2 infers that turnover intention can predict work engagement negatively, according to the result of regression analysis shown in figure 1, turnover intention can predict work engagement at T2 significantly ($\beta = -0.37$, $p < 0.001$).In summary, the relationship between work engagement and turnover intention can be proved.
Figure 1　Cross-lag Regression Analysis of Work Input and Turnover Intention

Note:The double arrowheads in the diagram represent the results of the correlation analysis (correlation coefficient r); the single arrow represents the result of the forced entry variable method (standardized regression coefficient β).

4 Conclusion

First of all, the two-way predictive relationship between work engagement and turnover intention is confirmed, which provides a new perspective for the study of causality between work engagement and turnover intention.So far, in the study of causality between turnover intention and work engagement, only some scholars have paid attention to the predictive effect of work engagement on turnover intention, and few studies have explored the negative prediction of turnover intention.The discovery of this research result not only enriches the research of causality between them, but also brings new enlightenment to practical management.

Secondly, it makes up for the lack of theoretical support in previous studies.Although some empirical studies have proved that work engagement can play a negative role in predicting turnover intention, there has been a lack of corresponding theory to support its view (Schaufeli & Bakker, 2004).This paper is based on the basic hypothesis of COR theory, three basic propositions: "the primacy of resource protection", "secondary nature of resource acquisition", "creating resource surplus", and the angle of gain spiral and loss spiral. The negative predictive effect of work engagement on turnover intention is explained in depth.In addition, based on the reciprocity principle and the sense of return of social exchange theory, this paper explains the predictive effect of turnover intention on work engagement, which enriches the macro application scope of social exchange theory.

Thirdly, this paper uses cross-lag analysis to explore the relationship between turnover intention and work engagement, further validates and extends the relevant research, and deepens the previous cross-sectional research.Most of the previous studies used cross-sectional data to analyze, but the cross-section research design cannot be very good to clarify the causal relationship between the two. The cross-lag analysis provides more powerful evidence to explain the causal relationship between work engagement and turnover intention.

Last but not least, this study brings some practical enlightenment to organizational management.HR authorities should regularly use the professional scale to assess employee turnover intention. For employees with high turnover tendency, the organization should pay enough attention to find out the root of the problem, solve the problem in time, and provide psychological counseling to reduce the negative emotion of the staff. Repair the social exchange relationship between employee and organization. If the overall turnover intention of the organization is high, we should conduct a thorough investigation, analyze and summarize the reasons, redeploy the human resources strategy, expand the scope of rectification and reform, deepen the reform, and thoroughly reduce the turnover rate of the organization. To promote their work engagement, to create more value, and to promote the development of the organization. For employees who are engaged in work, the organization should give timely and appropriate reward to the spirit or material. In this way, it not only increases the accumulation of resources in his resource pool, helps to enhance his ability to create new resources and creates more value for the organization, but also makes it in a value-added spiral state, so it is not easy to produce turnover intention. However, organizations should also be careful not to reward their employees too much, which may lead to rising expectations and it will be more difficult for the organization to maintain a social exchange relationship with them in the future. Therefore, only by accurately grasping the degree, can the organization help the staff to engage in the work, accumulate more resources in the organization, and achieve the goal of reducing the turnover of the staff.

Research on the Structural Optimization of Enterprise Teachers of Human Resources Management Based on Fuzzy Entropy[1]

Qiu Yangyang, Luo Fan
School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: qiuyy15@163.com, sailluof@126.com)

Abstract: In order to improve the construction of teachers, many colleges and universities invite some professional talents or skilled craftsmen to participate in the cultivation of school talents. Optimizing the structure of enterprise teachers is of great significance to the development of composite applied talents that meet the needs of society. Based on the sample data of Human Resource Management, this paper quantitatively analyzes the structure of enterprise teachers from four aspects: age, educational background, major, and graduation school. It uses fuzzy entropy to predict and analyze the enterprise teachers as well as proposes an optimization model and corresponding measures.
Key words: Enterprise teacher; Team structure optimization; Department of human resource management; Fuzzy entropy

1 Introduction

The former president of Tsinghua University, Mr. Mei Yiqi, once said: "University is not only a building but also has masters." It can be seen that the foundation of the school lies in the construction and optimization of the teaching team. At present, college students are faced with many difficulties in the process of finding a job. When employers recruit college students, they not only examine the theoretical knowledge of students, but also value the practical knowledge and ability. The difficult situation has become increasingly prominent. According to the Outline of the National Medium and Long-term Education Reform and Development Plan (2010-2020), the personnel training model of integrating work with learning, school-enterprise cooperation should be implemented. This study analyzes and optimize the structure of enterprise teachers to improve the quality of teaching, and cultivate complex application talents adapted to the needs of society, which has great practical significance.

At present, scholars at home and abroad research on the construction and structural optimization of enterprise teachers are mostly aimed at the theoretical research of higher vocational colleges. There is a lack of research and analysis on the optimization of enterprise teachers of colleges and universities. In addition, in related research at home and abroad, it has not been found that some scholars have conducted an in-depth analysis of the construction of enterprise teachers who major in Human Resource Management. The research results in this area are very few. Therefore, this study takes enterprise teachers that major in Human Resource Management as the object, carries on the quantitative analysis to its structural optimization, further enriches the research in this field.

The enterprise teacher is part-time teacher who has solid professional skill and the rich practical experience, participates in the cultivation of applied talents in universities, and undertakes certain teaching task. Enterprise teachers can effectively guide students to have an in-depth understanding of the company's positions; And can help students deepen the understanding of professional knowledge, learn to use the theoretical knowledge to find and solve problems; And can effectively help schools in the construction of teaching activities, teaching content, etc. It is of great significance to school development and student cultivation.

In order to improve the quality of teaching, the proportion of professional talents or skilled craftsmen hired form enterprises has been continuously increasing (Luo Xiaoqiu, 2010), and the part-time teachers form a growing proportion of the global Higher Education workforce (Beaton F, 2017). One scholar assessed the extent of use of part-time teachers in British higher education, the number is much more than the registered (Husbands C T, 2010). During the development process, some problems are gradually emerging. In response to the professional characteristics of enterprise teachers, many scholars have conducted relevant research on the appointment of enterprise teachers (Shao Jiandong, 2015), team building (Jia Wensheng and Liang Ningsen, 2015), and management mechanisms (Luo Xiaoqiu, 2010; Wang Lihua and Zou Jiquan, 2010). As a scholar put forward a new approach of developing effective part-time teachers in higher education (Beaton, Fran, Gilbert, et al., 2012).

---

[1] * Corresponding author.

However, there are few studies on the optimization of its structure, especially quantitative analysis. Relying on the reform of Central China Normal University, He Zhankui et al. (He Zhankui et al., 2014) summarized the practical exploration of full-time and part-time teacher's structural optimization and put forward the "5+4+1" structure model. Take Wuhan University of Technology as an example，This paper optimizes the construction of enterprise teachers major in Human Resource Management, and proposes corresponding optimization models and suggestions.

2 The Present Situation of Enterprise Teachers

In order to optimize the structure of enterprise teachers, the paper analyzes the status quo of the structure of enterprise teachers, including age structure, educational background structure, major structure, and graduation school structure. And in order to realize the quantitative analysis of the target, this paper takes 78 enterprise teachers in the Human Resource Management Department of Wuhan University of Technology as an example, to conduct quantitative analysis.

2.1 Age structure

The age structure refers to the proportion of teachers' age in the same period, that is, the ratio of old, medium and young people. A reasonable age structure means that the team can flow normally and continuously, and it is generally distributed normally. There will be no obvious peaks or troughs appear in all age groups, resulting in discontinuities (Lily Liu, 2010). Therefore, the faculty not only needs the constant injection of fresh blood by young teachers, but also need middle-aged teachers who are the backbones. And as well as need older teachers to enrich the teaching experience. At present, the average age of enterprise teachers major in Human Resource Management is about 38, and only 8.97% of them are over the age of 50. Most of them are middle-aged and young teachers, among whom 35-50 are the most, accounting for 56.41%, and those under 35 are 34.62%. As shown in Figure 1.
Figure 1   The Age Distribution of Enterprise Teachers

2.2 Educational background structure

The educational background structure is the proportion of teachers who have different degrees. The educational background structure can embody the theoretical foundation and professional qualities of the teachers and guarantee the quality of teaching and research. At present, there are doctor, master, and bachelor in the enterprise teacher talent pool. Among them, the number of enterprise teachers with a master's degree is the highest, accounting for 79.22%, and the number of them with a bachelor's degree account for 15.58%, and the proportion of doctorates with only 5.19%. As shown in Figure 2.

In the enterprise teacher talent pool, there are no specialist qualifications staffs. However, students need teachers who can actually guide them according to their actual situation，especially for undergraduates majoring in Human Resource Management. Therefore, the level of academic qualifications of enterprise teachers should constitute a certain gradient to meet student needs.
Figure 2   The Distribution of Enterprises Teachers' Educational Background

2.3 Major structure

The major structure is the ratio of the professional composition of the enterprise teachers. The enterprise teachers on the basis of their professional background, combine the practical experience and the actual research demand to apply the scientific research results to teaching and production practice, and better teach the knowledge to the students so as to improve the students' scientific research ability and popularization and application ability. In view of the weakness of students' practical application ability, enterprise teachers with different professional backgrounds are conducive to the intersection of disciplines, and their reasonable major structure is conducive to the cultivation of composite applied talents that meet the needs of society. At present, there are only 12.82% of enterprise teachers with human resource management background. Most of them are business administration and enterprise management teachers, accounting for 48.72% and 20.51% respectively, followed by a small number of management sciences and engineering major. As shown in Figure 3.
Figure 3   The Distribution of Enterprises Teachers' Major Structure

2.4 Graduation school structure

The graduation school structure refers to the proportion of the graduates from alma mater and other schools. The graduation school structure of the teaching team can influence the teaching idea and the academic thought of a school, and also has a great influence on the choice of teaching methods and contents. As shown in Figure 4, at present the enterprise teachers of Human Resource Management are mainly graduates from alma mater, which is as high as 84.62%, and most of them are tutored by the same tutor. There are very few enterprise teachers graduated from other colleges and universities. Although the selection and employment of teachers by tutors as a link to a certain extent facilitate the maintenance of the relationship between teachers and students, but in the long run, it may also cause "inbreeding" phenomenon, leading to a single academic thinking, lack of a variety of teaching ideas and academic ideas interchange.
Figure 4   The Distribution of Enterprises Teachers' Graduation School

3 The Establishment of Optimization Model

The ultimate goal of the construction of the enterprise teachers is to build a stable, professional and

sustainable teachers team, to make up for the shortcomings of traditional teaching practice, to improve the students' ability to use knowledge and to enhance their comprehensive competitiveness. Therefore, it is necessary to reasonably predict and optimize the age, educational background, major, and graduation school structure of enterprise teachers so as to better meet the needs of teaching development and improve the professional competence of students.
