

PROCEEDINGS OF THE 10th
INTERNATIONAL CONFERENCE ON
INNOVATION AND MANAGEMENT

December 2-4, 2013

Chief Editors

Arnoldo de Hoyos, Ken Kaminishi, Geert Duysters

Associate Editor

Wang Yingming, Ye Jianmu

Wuhan University of Technology Press

Wuhan, China

【Summary】

The proceedings include informatization, operation management and manufacturing innovation, product, industrial and regional Innovation, organizational, institutional and management innovation, environmental innovation and sustainable development, S&T policy, intellectual property and knowledge, university-industry collaboration and strategic alliance, and miscellaneous.

Proceedings of the 10th International Conference on Innovation & Management/ Wang Yingming, Ye Jianmu—Wuhan: Wuhan University of Technology Press, 2013.12

The 10th International Conference on Innovation and Management (ICIM 2013)

Organized and Hosted by

NEF- Pontifical Catholic University of Sao Paulo, Brazil

Co-organized by

Yamaguchi University, Japan

Eindhoven University of Technology

Tilburg University, The Netherlands

Wuhan University of Technology, China

Supported by

Brabant Center for Entrepreneurship, The Netherlands

Risk China Research Center at University of Toronto, Canada

School of Industrial Management, University of Vaasa, Finland

The Hubei Association of Science of Science and S&T Management, P.R. China

Wuhan-China Research Center for City S&T Policy and Management, P.R. China

Organizing Committee

Chairman:

Arnoldo DE HOYOS (NEF- Pontifical Catholic University of Sao Paulo, Brazil)

Co-Chairman:

Ken KAMINISHI (Yamaguchi University, Japan)

Greet DUYSTERS (Eindhoven University, The Netherlands)

WANG Yingming (Wuhan University of Technology, P.R.China)

Members: (In alphabetic order)

Alessandro Marco Rosini, André Furtado, Andyara Santis, Angelo Palmisano, Antonio Vico Mañas, Aquatias Christine, Ard-Pieter de Ma, Beatriz Marcos Telles, Chen Jing, Chen Xiaohong, Christine Syrgiannis, Cláudio Marte, Dash Wu, Deng Mingran, Diego Conti, Erika Zoeller Veras, Felipe Borini, Fernando Grisi, Flávia Pereira de Carvalho, He Shan, Hu Xiangpei, Hu Zhenhua, Irmtraut Mecke, Ivanete Bellucci, Jiang Dianchun, Jiang Zhongwei, John Rijpma, Kazuhiro Fukuyo, Koiti Egoshi, Ladislau Dowbor, Lennon Jardel de Araujo, Li Hua, Liu Xielin, Luiz Roberto Calado, Maria Cristina Amorim, Milton Campanário, Mônica Cairrão Rodrigues, Monique Greve, Motonobu Kubo, Nguyen Huu Phuc, Sun Shusheng, Roberto Bernardes, Rosa Alegria, Rosa Rizzi, Ruth Y. Lopez Trigo, Tales Andreassi, Telma Teixeira, Tim de Leeuw, Vinnicius Vieira, Vitoria C. Dib, Walter Mcmanus, Wei Jiang, Wim Vanhaverbeke, Xie Kefan, Nakio Ohshima, Yoshiyuki Matsuura

Executive Committee

Director:

Arnoldo de HOYOS (Pontificia Universidade Catolica de Sao Paulo, Brazil)

Members: (In alphabetic order)

Alessandro Marco Rosini, Antonio Vico Mañas, Chen Yun, Deng Mingran, Diego Conti, Erika Zoeller Veras, Fernando Grisi, Geert Duysters, Jiang Zhongwei, Kazuhiro Fukuyo, Kazuya Inaba, Ken Kaminishi, Ladislau Dowbor, Liu Yang, Mônica Cairrão Rodrigues, Motonobu Kubo, Naoki Ohshima, Nguyen Huu Phuc, Rosa Alegria, Rosa Rizzi, Ruth Yamada Lopez, Sakae Kawamura, Shigeyuki Haruyama, Telma Teixeira, Tomohisa Kimura, Vinnicius Vieira, Wang Yingming, Xie Kefan, Ye Jianmu, Yoko Ishino, Yoshiyuki Matsuura

CONTENTS

Part 1 Informationization, Operation Management and Manufacturing Innovation

The Common Integration: The Group Operation of Petrochemical Complexes in Japan Kazuya Inaba	1
Construction Organization and Management Based on Virtual Reality System Xu Jinbo	8
A Study of the Process Quality Control Based on Internal Customer Satisfaction Shui Xiangdong	13
A Study on the Evolution of Knowledge Management in Enterprise Production Process Wang Sipeng	17
Early-Warning Study of Heavy Deficit Based on Financial and Non-Financial Characteristics in Listed Companies of China Gong Haifang, Li Hongsong	21
Analysis of Internal Management of Chinese Banking Information System Sun Peng'an, Li Mingxing, Zhang Tongjian	27
Research on Measurement of Network Bandwidth Based on Adaptive Packet Pair Algorithm Wang Yunpeng	32
A Programming Model of Air Routing Problems with Hard Time Window Tang Zhifen, Xiao Hanbin, Chen Jianhua	36
Research on the Principle of the Risk Conduction Intensity in the Enterprise Financial System Deng Mingran, Wang Hui, Ma Ying	42
Logistics Engineering Curriculum Based on Experiential Learning Environment: An Example Liu Zhe	46
Analysis on Impact of China's Stock Index Futures on Stock Market Liquidity Hao Guiyan	50
Application Study of Heuristic Algorithm on Production Plan of Compounded Flow Production Guo Shuqin, Yu Zhongming, Ning Baoquan	56
Research on the Correlation of Financial Innovation and Economic Growth Liu Caijie	61

Research on Innovation Development and Risk Prevention of Logistics Financial Business of Commercial Banks in Wuhan City Circle	
Wang Zhenqiong	67
Research on Financing Mode of Strategic Emerging Industries in the Initial Development Stage	
Qi Xiangdong	74
Comparative Analysis on Characteristics and Countermeasures of China-US Shadow Banking	
Chen Jiyong, Zhen Zhen	78
Exchange Rate Pass-Through to Import and Export Prices: An Empirical Analysis in China	
Li Lianlian, Tian Yishun	84
The Relevant Research on Information Ability and Core Competence in Chinese State-owned Joint Stock Banks	
Su Hong , Hu Yahui , Zhang Tongjian, Li Mingxing	89
Study on Quantitative Evaluation of Comprehensive Transportation Planning Programs	
Tian Yishun, Li Lianlian	94
Comparative Study on Advanced Manufacture Industry Between Wuhan and the Five National Central Cities in China	
Liang Dong, Wang Huan	99
Determinants of Capital Structure of Chinese Manufacturing Firms: A Panel Regression Analysis	
A.B.M. Munibur Rahman, Fang Qiang	104
Research on the Competitiveness Analysis Model of Industrial Cluster in High-Tech Industrial Zone	
Zhan Yuanfang	110
A Study on the Marketing Channel Mode Innovation of Traditional Chinese Medicine Enterprises	
Guan Cuiling, Zu Guoqiang, Liu Hui, Qiu Yinggui	114

Part 2

Product, Industrial and Regional Innovation

A Combination Forecast Model of the Creative Talents Demand Based on Ant Colony Optimization Algorithm	
Li Woyuan, Zhang Qingpu, Qiao Jianmin	120
Industrial Competitiveness and Industrial Ecology: Case of RING Initiative in Japanese Oil-Related Industry	
Yoshiyuki Matsuura, Kazuya Inaba, Nguyen Huu Phuc	126
Research on the Influence of Index of CSTP to TFP: Based on the Empirical Research of Provincial Panel Data	
Zou Wei, Liu HuiLing, Wang Zhaoyang	134

Chinese Cement Industry Transition, Status Quo, Policy Trend and Challenge	
Guofei Ren, Kazuhiro Fukuyo	140
A Study on the FDI's Influence on the Technological Innovation Ability in Wuhan of China	
Wei Zhengfu	147
Regional Difference Regression Analysis of Contributions to GDP by Three Types of Patent	
Li Yahong	153
Evaluation of the Creativity of the Auto Industry in Liuzhou Based on Fuzzy Synthesis Method	
Li Ming, He Xuefeng, Jiang Zhangchun	159
What Lead to the Successful Mobile Phone Game?—Story of Birds Who Cannot Fly but They Have Enough Angriness	
Jaakko Iivonen, Yang liu	163
Research on the Predicament and Countermeasures of Opto-Electronic Information Industry Cluster Development in Wuhan East Lake High-Tech Development Zone	
Wang Yan, Cheng Yanxia	170
Market Risk and Its Prevention of Discontinuous Technological Innovation	
Liu Yaosheng, Yan Jingdong	175
Analysis of Synergy Development System of New Energy Automobile Industry	
Zhang Yan	180
Research on the Innovative Design of Tourism Products in Jingzhou of China	
Zhao Junjing	184
Synergy Innovation Pattern on New Energy Vehicles Industry	
Zhang Yan	188
Digital Workflow of Standard Inspection Processes in Automotive Manufacturing	
Maw Maw Htay, Guo Shunsheng, Asa Romeo Asa, Sun Libo	192
Research on Independent Brand System Strategy of Special Vehicle	
Wang Hui, Wu Yu	197
Study on the Influence of Science and Technology Innovation on International Service Outsourcing in Jilin Province of China	
Liu Liqin, Liu Xiaohui	201
Research on the Endogenous Impetus of Strategic Emerging Industrial Cluster Development	
Jiang Wei, Diao Zhaofeng	206
Low Carbon Technology Innovation of Chinese Petrochemical Industry: Challenges, Strategy and Approaches	
Zhang Yongning, Qu Yan, Shen Jihua, Yang Zaiqiang	209
Functions of Design Management on Upgrading Industrial Design in China	
Zhou Ziqin	214

A Study on the Growth of Emerging Economies and Their National Income Distribution	
Chirinos Adriana	218
Countermeasures of the Industrial Energy Consumption Based on the Industrial Economic Increase in Wuhan of China	
Li Zhihong	223
The Building of Excellent Vehicle Brands: Research on Vehicle Brand-quality Chain and Its Operation Mechanism	
Liu Jieming, Cheng Ju, Cai Chen	229
Research on Identification of Core Competence of Disruptive Technological Innovation Network Partners	
Sun Shenglan	234
Product Architecture Embedded in Mobile Internet: An Exploratory Study	
Yu Yan, Gu Yuanxun	238
Technology Diffusion of Cloud Computing	
Tiina Liimatainen, Yang Liu	243
A Study of Concept Structure of PMBOK Based on Graph Theory	
Naoki Ohshima	248
Firm's Key Success Factors in Power Electronics Segment Based on the Dynamic Capabilities and Flexible Business Concept	
Jari Koskinen, Josu Takala, Joseph Sebuwufu Awali	253
The Current Situation and Strategy Choice of Technology Sourcing Foreign Direct Investment in the U.S. by Chinese Enterprises	
Huang Ying	259
A Study on Credibility in Product Market and Its Influence on the Market Transaction	
Jin Qin, Zhang Huaimin	265
Research on the Grain Processing Industry in the Central Region of China	
Li Minjing	269
Analysis on Logistics Infrastructures Site Selection Model	
Xun Wei	274
Research on the Implicit Theories of Creativity of Industrial Designers in China	
Zhang Hongtao	279
Research on Coupling Characteristics and Mechanism of Product Innovation Design Risk Conduction	
Deng Jun	285
Evaluating and Studying Tourism Industrial Structure Benefit of Hubei Province of China	
Luo Xiaoli	289

Study on the Construction of Industrial Safety Evaluation Indicator System	
Zhu Jianmin	293
A Research on Systemic Management of Product Design	
Cui Yongying	298
A Study on the Importance of Business Model Innovation in Strategic Emerging Industries	
Wang Zhaojie	303
Research Trend of Technology Management	
Yoko Ishino	307
The Complexity Vision for Online Development	
Cana Maria Di Grado Hessel, Ivani Catarina Arantes Fazenda	313
Design-Co-Cost Framework in Product design Using Inventive Problem Solving Technique (TRIZ)	
Nooh Abu Bakar, Zulhasni Abdul Rahim	321
Trends in industrial R&D in India from 1996-2011: An Analysis	
Nirmalya Bagchi	330
Functions of Design Management on Promoting Animation Industry in China	
Gong Qifang	340
Research Overview of the Evaluation Index System on the Development Level of Public Libraries	
Chen Yaqian	345
A Conceptual Model of Peer Influences Towards the Adoption of Technological Innovations among Young Adult Consumers	
Eric V. Bindah, Md Nor Othman	350

Part 3

Organizational, Institutional and Management Innovation

The Research on Relationship Between Competency and Job Performance of Marketers	
Du Dayou, Ma Lu	357
Meta Analysis of the Relationship Between Intellectual Capital and Organization Performance	
Qin Hui, Wang Yuwei	362
The Exploration into the Safety Education and Management of College Students Based on “Students’ Organization”	
Wang Shijie, Ma Jiaming, Tang Shihui	367
Imitation & Innovation in Emerging Countries: A Conceptual Framework for Analysis	
Nguyen Huu Phuc	371

Research on Inner Circulation Mechanism of Security Housing	
Han Fang, Diao Zhaofeng	378
Empirical Research on Innovation Path Selection of Express Service Company	
Zhang Jianming	382
The Process of Global Brand Strategy Development and Regional Implementation	
Davit Mkhitarian	388
ISCO Four-Dimensional Structure Model of Design Management Innovation System	
Ma Hongyu, Hu Shuhua, Zhang Ziyan	393
Research on the Synergetic Performance Evaluation of High-Tech Enterprises	
Chen Ruiqing, Wang Liyan, Yang Qing	398
The Proposal of Metrics and Evaluation Methods to Explicit Knowledge of the Absorptive Capacity	
Kenji Miyake, Yoshiyuki Matsuura, Ken Kaminishi	403
The Impact of Customer Participation on Innovation Capability: Moderating Role of Power Asymmetry	
He Yong, Zhang Jing	412
An Empirical Analysis on Information-Based Innovation System in Chinese Enterprises	
Xie Yan, Su Hong, Zhang Tongjian, Li Mingxing	425
Direction and Principles Research of Risk Transmission in Business Finance System	
Deng Mingran, Tang Pingqiu, Chen Yun	429
Why Is a Bitten Apple: Thinking on Non-Perfectionism Corporate Culture	
Feng Xilin, Yang Huaizhong, Xiao Zhonghua	433
Study on the Mechanism Analysis and Long-Effect Countermeasure of Misappropriation of Public Funds as Private Department Coffers	
Zhou Guoqiang, Huang Mingli, Zhang Peilin	438
A Debate on the Influence of National Culture in Organizations	
Arnoldo José de Hoyos Guevara, Clarice Santiago, Diego de Melo Conti, Francine Wey	443
Analyzing In-Store Shopping Paths from Indirect Observation with RFID Tags Communication Data	
Toshiki Fujino, Masaki Kitazawa, Takashi Yamada, Masakazu Takahashi, Gaku Yamamoto, Atsushi Yoshikawa, Takao Terano	448
Research on Real Estate Regulation Measures under the Supply and Demand Models	
Yu Yao	455
Analysis on Informal Finance Risk Conduction Effect under Asymmetric Information Condition	
Huang Jian, Wang Xueqin, Xia Xue	460
Evaluation of Public Satisfaction Towards Governmental Public Sectors Based on SEM	
Gong Kelan, Liu Guolong	466

Research on Distribution Model Innovation of the Fresh Agricultural Products	
Li Shihua	470
Coupling Mechanism Between Sports Industry and Ecological Environment in the Low-carbon Economic Era	
Zhao Ying	475
Organizational Forms for Collaborative Learning at Different Structures of Social Networks: China as an Example	
Chen Silu, Chen Hsinghung	480
Study on the Key Indices of Government Emergency Management Capability of Major Public Health Paroxysmal Incident in China	
Zhu Jiangbin, Xiong Min, Wang Chong	487
Study on Influencing Factors of Business Model Innovation Based on Social Network Analysis	
Wang Bingcheng, Ding Hao, Yang Fang	491
International Marketing: Innovative Strategies for Entering Foreign Market	
Abdoulaye Oury Bah, Argelia Munoz Pahuamba	495
Research on Construction of Informal Finance Risk Early Warning System and Empirical Data	
Lu Bin, Deng Mingran, Huang Ling, Jiang Xianglin, Shen Jun	502
Diversity and Innovation: Empowering Women Fosters Innovation	
Yuko Hayashi	508
Research on Passenger Satisfaction and Behavioral Intention under the Situation of Flight Delay Based on SEM	
Wang Zheng, Liu Xiaoping	514
The Construction of Quality Management System of Commissioned Audit in Higher Education Institutions' Construction Projects	
Zhou Yuan	518
Employee Motivation and Satisfaction in Niger: An Application of the Job Characteristics Model	
NABA Boukari Moctar, Luo Fan	523
Study on Innovative Development Strategy for the Private Economy of Wuhan of China	
Zhang Jun	528
Research on the Serious Transfer Path of Supply Chain Risk	
Qiu Yinggui	533
Research on the Structure and Function of Enterprise R&D Knowledge Management Platform	
Yin Xilin, Cheng Huan	537
Research on Price Regulating Structure of Medical Expenditure on the Condition of Non-separation of Hospital and Medicine Enterprises	
Gu Xingong	541

Creation of Value Through the Transformation Program in University Teknologi Malaysia	
Ahmad Rahman Songip, Zaini Ujang	548
Understanding the Impact of ‘Hard’ and ‘Soft’ elements of TQM in South-East European Firms	
Shpend Imeri, Tauno Kekäle	554
Improving the Efficiency of Sci-tech Novelty Search Based on EndNote	
Zhao Fenghua, Yang Bo	559
Research on Actuality and Countermeasures of Innovative Talents Incubation for RG Petro-Machinery (Group) Co. Ltd	
Feng Cao, He Xingyi, Yan Jingdong	563
Informally Institutional Reform of Taxi Regulation	
Ding Yunlong, Wang Wei	567
Research on Sports Resources Development and Management Countermeasures in Rural China	
Ai Xiangnan	571
The Structure of Theoretical Framework about Strategic Management Audit	
Guan Yamei	576
A Study on the Relationship Between Organizational Ethical Climate and Employee’s Anti-Ethical Behavior	
Ma Lu, Du Mingfei, Zhu Xin	581
An Empirical Analysis on the Coordination of Interest Allocation among Employee-Stockholder & Government and Its Correlation to ROE: A Case of 66 Manufacturing Listed Companies in Japan	
Wang Weiping, Guan Huailiu	586
Research on the Guarantee of Efficient Operation on Teaching System to Cultivate Excellent Talents in International Cooperation	
Dai Fuxiang	593
The Role Positioning and Countermeasures of Local Government Process Reengineering Based on Administrative System Reform	
Zhang Hao, Ding Yunlong	597
Policy Research on Human Resource Development of Disabled Persons in Our New Period	
Ai Liang, Luo Dan	605
Cross-Border Spillovers from Local Fiscal Expenditure: Evidence from Cities in the Yangtze River Delta	
Yin Desheng, Huang Wenqian	610
Study on Influencing Factors and Countermeasures of College students’ Entrepreneurship	
Li Xiaobei	615
Credit Risk Assessment of Commercial Bank of Ethiopia with Special Emphasis to the Prioritized Sectors	
Eskinder Asfaw Bantiwalu	620

Statistical Analysis of Academic Studies on Innovation and Management in the Last Decade in China	
She Yilin, Zhang Quanle, Wu Zhenghao	627
Operation Performance Analysis of Enterprise Complex System form the View of Synergy	
Xu Jun	633
Expert Counseling Model Based on Life Cycle Theory	
Zhu Hanxiong, Xu Yahe	637
Mode of the State-Subsidized Student Loan System in China	
Shang Dan	643
The Reform of US Financial Supervision after Sub-Prime Crisis and Its Implications to Chinese Financial Supervision	
Huang Zihua	647
Marketing Mix and Adaptation Strategy of Commercial Banks in a Fragile Economy: A Case Study on the Congo D.R.	
Mbayo Kabango Christian	652
Selection and Evaluation of the Tenant Enterprises for Industrial Base on FAHP	
Wang Jing, Zhong Mingxia	659
Research on Undergraduate Technology Innovation Base Construction	
Zeng Bo, Fang Haining, Hou Fei, Jiang Yan	664
Mental Health Service System Innovation in University: Application of Case Management	
Li Qian	668
Institutional Innovation: Path Selection for Increasing Soft Power of Culture of Clean Governance	
Li Xiaoqin	673
A Rustic Opinion on the Quality of Scientific and Technical Periodicals in China	
Luo Yixin	678
A Critical Analysis of Two Motivation Theories and Their Application	
Huang Yang	681
A Discussion on the Dynamic Mechanism of the Management Innovation of Pale-biotic Fossil	
Han Gang, Liu Xueling, Han Lizhuo, Pan Ling, Guo Zhichuen	685
Innovations in Public Transportation Privatization in China and Its Reflection	
Zhao Ying	690
The Innovation of Regulation of Food Safety Management and System Innovation: The System of Public Participation	
Wang Li	694
Innovation in Teaching Strategy: Using of Sports as Cognitive Metaphor	
Rozhan Othman, Khor Minee	700

Talent Retention Strategies in Different Organizational Contexts and Intention of Talents to Remain in the Company	
Elza Fátima Rosa Veloso, Rodrigo Cunha da Silva, Joel Souza Dutra, André Luiz Fischer, Leonardo Nelmi Trevisan.....	705
Analysis on the Critical Factors of Leading Figures' Impacts on the Performance of Enterprise Innovation Teams	
Dou Han, Chen Yun, Zhong Qian.....	713
An Empirical Study on Capital Allocation Efficiency of Listed Companies in Hubei Province of China	
Huang Xiaobo, Hu Shiyu	718
Research on Evaluation of Customer Knowledge Management Competence	
Wu Jing.....	723
Barriers and Countermeasures of Information Sharing in Emergency Management	
Zhang Ping, Luo Wei, Su Min	728
A Research on the Operating Mechanism of the Management Innovation of Pale-biotic Fossil	
Liu Xueling, Han Gang, Han Lizhuo, Pan Ling , Guo Zhichuen,.....	732
On the Institutional Innovation of Resettlement Compensation of Water Conservancy and Hydropower Projects in China	
Luo Yongneng.....	738
An Innovative Thinking on the Concepts of <i>Ex-Ante</i> Value, <i>Ex-Post</i> Value and the Realized Value (Price)	
Mohammad Ali Tareq.....	745
A Study on Purchase of Service Contracting and Community Care for the Disabled	
An Zhimin.....	752
Tourists' Attitude Towards Service Marketing Mixes: An Empirical Study on Cox's Bazar Sea Beach in Bangladesh	
Mohammad Amzad Hossain Sarker, Sumayya Begum, Wang Aimin.....	759
A DEA-based Efficiency Study of Service Industries in 19 Central Cities in China	
Wu Lixia, Yun Jun.....	766

Part 4

Environmental Innovation and Sustainable Development

Study on the Regional System Vulnerability Evaluation: Taking China's Hebei Province City Group as Example	
Feng Zhenhuan, Jia Shanshan, Wang Lina.....	772

Assessment on Wuhan’s Industrial Sustainable Development Capacity under Ecological Environmental Constraints	
Pang Guoqiang, Wei Jianguo, Zhu Chun	778
Inserting the Topic of Sustainability in the Business Strategy of 20 Model Companies in Brazil	
Marcus Nakagawa, Beatriz Marcos Telles, Arnaldo de Hoyos Guevara	784
The Status and Problems of Resource-Based Industries in Inner Mongolia in China	
Wang Shuli, Yun Jilong	796
Study on the Multi-Objective Early Warning System of City Economic and Social Development	
Cai Wentao, Yang Qing	801
A Study on Concepts of Product Design with Sustainable Development	
Zhu He, Yang Xianyi	805
A Study on the Development and Reform of Sustainable Design	
Li Shuo, Zhan Wei	809
Study on the Sustainable Development of Wudang Wushu Cultural Tourism	
Yi Peng, Liu Mingming	814
Research on Low Carbon Performance and Enterprise Value	
Wang Zhiliang , Jiang Zhifang	819
The Research on the Effect of Mobile Subscribers’ Perception and Behavior on Mobile Number Portability (MNP): Case Study of MNP in Kumasi Metropolis	
Daniel Ofori, Ye Haiyan, Zhu Jinsheng	824
Ethics for Sustainable Development	
Christine Syrgiannis, Ivani Catarina Arantes Fazenda	830
Effective Building of Human Environment of Hi-Tech Industrial Clusters Based on Organization Ecology	
Zhang Ganggang, Ma Tao	835
An Exploration for the Rules of Hierarchical Design in Pictorial Map in Tourist Area	
Yao Hongting, Xiong Wenfei	840
A Study on the Influence of FDI, R&D on the Energy Intensity in Central Region	
Wang Haiyou	845
A Study of Driving-Force/Press Impact Model for Green Supply Chain Management	
Wei Feng, Luo Jianming, Li Weizhao	850
A Research Based on the Local Literature Service Mode under the New Media Environment	
Fu Peng	857
Exploring Low-Carbon Development Model in China	
Li Zheng, Tian Yuanyu, Qiao Yingyun	864
Teacher Education for Sustainability in Pakistan	
Nabi Bux Jumani, Faheem Abbasi	869

Theoretical and Empirical Thoughts on the Development of Low-Carbon Buildings	
Pan Guangyu.....	874
The Urgency of Civic Education and Youth Policy to Sustainability of Innovative Cities in Postmodernity: A Report of the Legislative's School of Pouso Alegre (MG)	
Beatriz Marcos Telles, Maria do Carmo Freitas Macedo, Ana Carolina de Faria Silvestre, Arnoldo de Hoyos Guevara, Mônica Fonseca Franco	878
Chasing Eco-Advantage: What Drives Eco-Innovations in Brazil	
Flavia Carvalho.....	886

Part 5

S&T Policy, Intellectual Property and Knowledge

Research on Evaluation Index of Commercial Bank Knowledge Management Based on AHP	
Chen Xiaofang, Huang Wencai	897
An Empirical Investigation into the Relationship Between Knowledge Management and Innovation Performance of Virtual Enterprise	
Feng Yanfei, Cai Lu	902
Patents Forecasting Based on Combination Regression Analysis	
Xie Yi.....	908
Research on Operation Mode and Risk Pre-Control Path of Technology-Finance Collaboration	
Zhang Youtang, Zhang Hong.....	912
Analysis on the Constraints of the Voluntary Food Safety Regulations on the SMEs	
Ye Haiyan	918
Research on Enterprise Information Security Risk Management	
Wu Xiaoyan, Yuan Hong, Lin Hua	924
Study on Requirements of R&D Knowledge Management System of Enterprise	
Yin Guoli, Yin Xilin.....	928
A Study of Technology Trends Analysis Using Patent Search Systems	
Shigeyuki Haruyama, Aidil Khaidir Bin Muhamad, Tadayuki Kyoutani, Kenji Miyake, Tomohisa Kimura, Ken Kaminishi.....	933
Research on Corporate Network Response after Product Harm Crisis	
Yang Limao, Wang Yuling.....	945
A Research on the Strategies of Intellectual Property Protection Based on the View of Knowledge Management	
Chen Yongzhi, Qian Zuoqin, Gao Lan.....	951

Study on the Correlation Between Informationization Construction and Knowledge Transformation in Chinese Enterprises	
Deng Jian, Xie Yan, Zhang Tongjian, Li Mingxing	955
Study on the Local Government Project Promotion Strategy from the View of Investment and Financing Management	
Zhao Yanpu, Zou Huixia, Yue Xiufa	961
Small Incentive and Big Economic Fluctuation	
Wei Jingqiang, Wu Jingxi	966
Oriental Comparisons of University Libraries and Public Libraries: China as an Example	
Lv Jingping	971
Intellectual Property Management of Digital Publication in China: Some Problems and Solutions	
Chen Jundong	978
An Innovative Model for China's Patent Management: Based on Analysis of China's Current Patent Law	
Qi Haiyan	982
Puzzles and Solutions of China's Intellectual Property Culture Construction	
Shu Yuan	987
Research of First Mover Advantage of Innovational Brand Equity	
Liu Guolong, Wei Fang	993
The Optimal Allocation of Regional Science and Technology Resources Based on Cooperative Game Theory	
Lou Yuhua, Shen Chi	999
Conversion Management of Patent Achievements in Colleges and Universities of China Based on Triple Helix Model	
Yuan Dachao	1002
Research on the Policy System in the Construction and Development of Wuhan City Circle	
Ma Hui, Zhang Mengjing	1007

Part 6

University-Industry Collaboration and Strategic Alliance

Business Associations, Horizontal Joint Action and Upgrading In Industrial Clusters	
He Bin	1011
IT Industry Development and the Role of Regional University: The Case of Ruby Course at Shimane University	
Yoshiyuki Matsuura, Tetsuo Noda, Naomi Takashimizu, Mikiyo Satoh	1015

Reviewing Service Quality in Higher Education	
Sanaz Farjam, Xu Hongyi	1020
An International Comparative Study on the Features of University-Industry Linkage Modes	
Wan Zi	1030
A Case Study on the Means of Distributed Innovation in Iron and Steel Industry	
Li Tielin, Liu Guoxin, Yang Kun	1035
Open Innovation: An Opportunity for Pharmerging Countries to Close the Technology Gap?	
Hind Louiza Chitour, Yang Qing	1043
Factors Impacting International Marketing: Configuring Strategies and Incorporating Co-Opetition	
Casius Darroux, Sun Xixiang	1056
A Theoretical Framework of the Knowledge Stickiness of Distributed Innovation	
Yang Kun, Liu Guoxin, Li Chen	1063
A Study on Influence Factors of Uncertainty of the Enterprise Financial System	
Deng Mingran, Wang Pengjie, Fang Ming	1069
Research on the Driving Mechanism of Intermediary Business Development of Chinese Commercial Banks	
Hu Jing, Bai Xiaozhong	1073

Part 7

Miscellaneous

The Level of Development of the Inland Open Economy in Central China	
Wang Shuli, Qiu Minrong	1078
Evaluation of Cultural Tourism Competitiveness Based on Catastrophe Progression Method	
Mao Chencheng	1083
Empirical Study on Interactive Development Between Manufacturing and Logistics Industry in Hubei Province of China	
Cao Aiping	1090
Research on Teaching Evaluation of Higher Education Programs Taught in English for International Students: Taking Teaching Practice in Wuhan University of Technology as an Example	
Yang Hongxin, Chen Yun, Yang Caixia	1101
Study on Simulation Model for University Mass Events	
Cai Chun	1106
Empirical Analysis of China's Coal Consumption, Carbon Emissions and Economic Output	
Wu Xiang, Li Shengnan	1111

Sino-Brazilian Relations and the Soft Power Cultural Exchange	
Erika Zoeller VÉras, Daniel Bicudo VÉras	1116
Study on Influencing Factors on the Sense of Belonging to the City of the Migrant Workers' Children in Wuhan of China	
Li Fang, Wang Kangjing	1124
Empirical Research on E-Commerce Performance System Based on Chinese Enterprises Data	
Hu Yahui, Su Hong, Zhang Tongjian, Li Mingxing	1129
The Global Company, Inequality and Employment	
Mozart Nino	1133
Analysis of User Experience in Brand Marking	
He Fang, Pei Lian, Zhu Xiayan	1145
Analysis of Residents' Leisure Behavior in Medium-Sized City: A Case Study of Xianning City of China	
Li Jiangmin, Tan Lijuan, Mo Qinrong	1150
Risk Management of REITs in China	
Cheng Jianjun, Yang Meiju	1156
An Analysis of the Chinese Firms Investments Political Risks in West Africa	
NABA Boukari Moctar, Chen Xiaofang	1160
A Theoretical Study on Health Quotient Promotion-based Physical Education Reform at the University Level	
Fu Junfen	1164
School Physical Education and the Chinese National Sports Culture Innovation	
Zhong Pengfei	1170
An Empirical Research of RMB Real Exchange Rate Volatility Effect on Sino-Japan Trade	
Zhou Ye	1177
Analysis on the International Marketing of Bottom Billion Economies	
Asa Romeo Asa, Navneel Shalendra Prasad, Maw Maw Htay	1182
Comparative Experience of Trade Relationships Between Mexico and China	
Argelia Munoz Pahuamba, Ye Jianmu, Abdoulaye Oury Bah	1187
An Empirical Analysis on Passenger Unexpected Events of Civil Airports under Flight Delays Scenarios	
Wan Chunhui	1194
Evaluation on Performance Management of Vehicle Repair Cost Effectiveness Based on F-AHP	
Zhang Jian, Han Wentao	1198
An Empirical Research on Competitiveness Evaluation of Services Based on Factor and Cluster Analysis: Taking 30 Provinces in China as Example	
Huang Mingjiang, Shou Xiangcheng, Xu Hongyi	1203

The Common Integration: The Group Operation of Petrochemical Complexes in Japan*

Kazuya Inaba

Graduate School-Management of Technology, Yamaguchi University, Japan

(E-mail:inaba@yamaguchi-u.ac.jp)

Abstract: Oil and petrochemical companies are in the severe situation where they should deal with various problems. In Europe, America, the Middle East, and East Asia (China, Taiwan, and South Korea), one company usually builds a large-scale factory, and consistently produces oil and petrochemical goods in the system of one company. Differently from it, two or more companies are concentrated in the coast landfills in Japan, and generally manufacture in the system of groups. The system of production in a petrochemical complex would be a medium-scale level if it sees worldwide. After World War II, capital was insufficient in Japan. Many companies advanced to the oil and petrochemical industry which seemed to have a big future. Small and medium scale factories were constructed. As a result, petrochemical complexes have been formed with the system of groups.

After the defeat of World War II, many oil companies excluding Idemitsu Kosan Co., Ltd. were organized for the supply of crude oil from European and American oil majors. They were devoted to refining oil and selling it only in Japan. Moreover, the oil market in Japan had been defended by restriction of the government. Such a system continued for years. Therefore, domestic oil companies had been aiming at improvement and efficiency of refining capacity. Their concentrating on technological development, cost reduction, and domestic share fought in the same industry had become a main activity. The construction of global competitiveness had been postponed for a while. However, after repealing protected laws, the import liberalization of petroleum product had been taken since 1996, and cheap petroleum products had flown in from foreign countries. The sales price had not become the same, and free competition under market mechanism had started. As a result, the movement of industry reorganization had been accelerated.

In such a severe situation, oil and petrochemical companies came up with the idea of business cooperation in the same region in order to acquire global competitiveness. 20 companies in oil industry and chemical industry gathered round at first. Under the Research Association of Technology Law, Research Association of Refinery Integration for Group-Operation (RING) was established in 2000. In order to gain global competitiveness, RING has acted group-operation programs in the industrial complexes in Japan. In this paper, I describe the historical formation and development of petrochemical complexes in Japan. And I consider and analyze the approach to and ways of the high-level integration for group operation. And I will explain the meaning of the plans, and the economies arising from the group operation business.

Key words: Petrochemical complex; Oil and petrochemical industry; Group operation; Sustainable development; Business cooperation; Energy conservation; Environmental measures; Industrial complex; Management of sustainability

1 Introduction

The circumstances that surround the oil and petrochemical industry recently have been severe. Oil and petrochemical companies are in the situation where they should deal with various problems. These subjects are global competitiveness setting between oil and petrochemical companies, sudden rise of price of raw material, response to environmental issues, minimization of resource energy consumption, security of safety technology, employment and economical contribution to the region, requirement to satisfy severe product quality standard, further upgrade and cost reduction in system of production, and construction of system of production to share at sustainable development etc.. In Japan, oil and petrochemical companies have taken up matters of energy saving measure, actions on environmental problems, security of global competitiveness, and restructuring of system of production etc..

In Europe, America, the Middle East, and East Asia (China, Taiwan, and South Korea), one company usually builds a large-scale factory, and consistently produces oil and petrochemical goods in

* This paper is written, based on my presentation paper in ICIM 2010, 2011 and EBHA-BHSJ Paris 2012, and I added retouches and corrections to it.

the system of one company. Differently from it, two or more companies are concentrated in the coast landfills in Japan, and generally manufacture in the system of groups. The system of production in a petrochemical complex would be a medium-scale level if it sees worldwide. There is the reason by which this system was generated.

After World War II, capital was insufficient in Japan. Many companies advanced to the oil and petrochemical industry which seemed to have a big future. Small and medium scale factories were constructed. As a result, petrochemical complexes have been formed with the system of groups. They had competed and cooperated at times, and fought for the share with repeating excessive competition.

After the defeat of World War II, many oil companies excluding Idemitsu Kosan Co., Ltd. were organized for the supply of crude oil from European and American oil majors. They were devoted to refining oil and selling it only in Japan. Moreover, the oil market in Japan had been defended by restriction of the government. Such a system continued for years. Therefore, domestic oil companies had been aiming at improvement and efficiency of refining capacity. Their concentrating on technological development, cost reduction, and domestic share fought in the same industry had become a main activity. The construction of global competitiveness had been postponed for a while.

However, Provisional Law on Importation of Specific Petroleum Products and Revision of volatile oil sales were abolished in 1996; the self-service gas station was permitted in 1998; and the Petroleum Act Law was abolished in 2001. After repealing these laws, the import liberalization of petroleum product had been taken, and cheap petroleum products had flown in from foreign countries. The sales price had not become the same, and free competition under market mechanism had started. As a result, the movement of industry reorganization had been accelerated.

On the change of oil and chemical industry in the world and domestic deregulation, the reorganization and integration of oil companies was done in Japan. The Nippon Oil group came into existence from a merge of Nippon Oil and Mitsubishi Oil Co., Ltd. and the purchase of Koa Oil Co.¹ in the refinement section. The megamerger of Nippon Oil Corp. and Japan Energy Corp. is scheduled in 2010. According to the flow of internationalization and deregulation, they carried it out to have global competitiveness. In Japan, oil enterprises have been reorganized and integrated other than mobile Exxon and Idemitsu Kosan Co., Ltd..

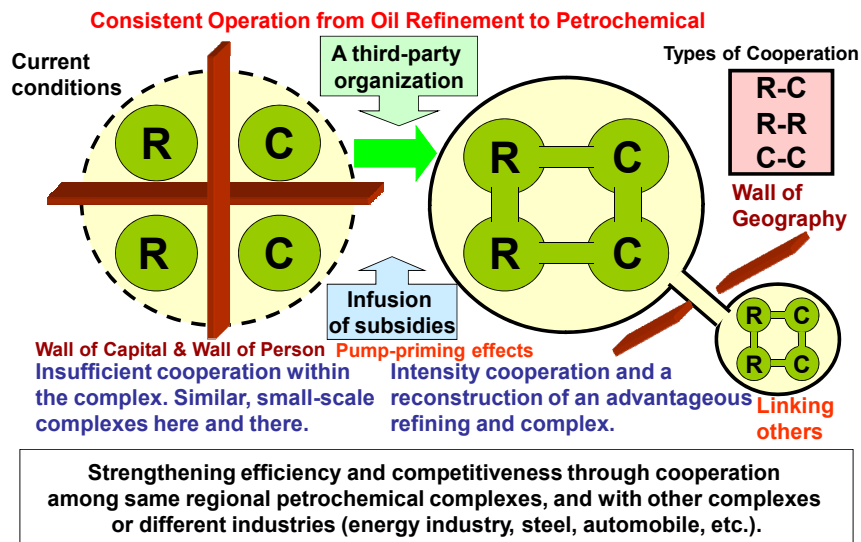

In such a severe competitive situation, oil and petrochemical companies came up with the idea of business cooperation in the same region in order to acquire global competitiveness. In this paper, the approach and ways of the high-level integration for group operation in petrochemical complex are analyzed, the meaning of the plan is declared, and the economy that arises from the group operation business is considered. Cooperation with some businesses would be effective for energy conservation and environmental measures, and would advance the possibility to achieve economies of social interests. Also, group operation would break the stoppage and promote innovations of manufacturing technology one after another.

2 Strengthening Competitiveness of Petrochemical Complex and Establishment of RING

Strengthening cost competitiveness is requested in oil and petrochemical enterprises in Japan. In the latter half of the 1990's, the merge and reorganization had advanced, and cost reduction had been attempted with efficiency improvement of production facilities. They had pulled out of unprofitable businesses. Positive investments in core business and growth business and participation in foreign complexes had made the business integration and competition stronger. However, the reorganization and integration of oil and petrochemical companies in Japan, if it is seen in the scale, is internationally the medium-scale one. It has faults that many operational companies are independent and production facilities have been distributed to many places. The equipment of oil and petrochemical companies in petrochemical complexes are widely distributed to eight places in the whole country. One company has production facilities in some complexes. The consolidation and expansion of manufacturing scale, efficiency improvement in manufacturing process, and reduction in cost of manufacturing are more necessary to obtain global competitiveness. But one company can't do them alone.

¹ Kazuya, Inaba., "Sengoki ni okeru Kowa Sekiyu no Kigyo Katudo - Gaisi Teikei kara Shin Nippon Sekiyu Seisei heno Gappei made - [The Enterprise Activities of Koa Oil after World War II - From Foreign Capital Alliances to Merge of Nippon Oil]", *Tiiki to Kigyo - Yamaguchiken Combinat Kanren Kigyo wo tyusin ni* [The Region and the Enterprise - Concerning the Enterprises related to Petrochemical Complex in Yamaguchi Prefecture -], Tokuyama University Economic Research Institute Library, 2004, pp.1-33.

It has been said that weak points of oil and petrochemical companies in Japan are halfway of cost reduction in medium-scale production, excessive competition, surplus of production scale, low degree of rate of profit. Petrochemical complexes of Japan have production facilities at a medium-scale level. It is in the situation in which economies of scale cannot be requested. And the equipment of one company is distributed to two or more districts. It is also difficult to consolidate these in one place. Many enterprises, concentrated in the same district, often belong to different capital groups. There are examples of producing same products by different manufacturing methods in the same district, too. In such a system, each company respectively has continued to conduct business actions, making decisions independently. Unfortunately, if the company is different, the organizational culture is also different and the spoken jargon tends to be dissimilar. There was an assumption not to communicate with each other easily in the situation. They has called these things "Wall of person", "Wall of capital", and "Wall of geography".

Looking at the technical side, oil and petrochemical companies in Japan had some problems and subjects. These were response to pollution and environmental issues, measures to conserve energy in the two Oil Crises, shift from general-purpose to high value-added product¹, and cost reduction. They had dealt with them, and historically developed and accumulated technologies for them. Also, recycling technologies have been developed². Environmental and saving resources technologies of Japanese enterprise have been evaluated throughout the world. These technologies in oil and petrochemical business are especially important.

To solve the problems, 20 companies in oil industry and chemical industry gathered round at first. Under the Research Association of Technology Law, Research Association of Refinery Integration for Group-Operation (RING) was established in 2000. RING has acted group-operation programs in complex, which the Ministry of Economy, Trade and Industry has supported since 2000. In RING projects, they have tried to find new methods of integrated management, exceeding types of business and a frame of capital, developing some latest technologies, aiming at efficiency improvement and optimization. It is important that one complex is thought of as virtual one factory. If it is so, the integrated management could be practiced. As a result, new effects, economies and innovations by new technological development would be achieved. These practices are difficult for one company to do alone.

In RING, the research and development business, related to advanced united management, has been done between different types of business such as oil and petrochemical factory, etc. The first R&D

¹ This had the purpose to evade domestic excessive competition and pursuit of petrochemical manufacturers in East Asian nations.

² Kazuya Inaba 'The Upgrade of petrochemical industry by recycling business -Concerning the Case of the Chemical Recycling for Polyester in Teijin Limited-', PROCEEDINGS OF PRESENTATION PAPERS, The 4th International Conference on Innovation & Management, The Organizing Committee of ICIM2007, Yamaguchi University, 2007, pp265-70.

project (RING 1) had got good results of the proof of R&D in the each district. It had resulted that strong unity was caused among complex enterprises through these activities. Following this, the second R&D project (RING 2) was executed in 2003. Development of advanced, highly integrated technologies for reducing environmental burdens was performed there. In addition, the action to optimize entire petrochemical complex and carry out advanced function unification was executed in the third R&D project (RING 3) in 2006. At present, such a business has been accomplished in most complexes in Japan, that is, in Kashima, Chiba, Kawasaki, Chita, Sakai Senboku, Mizushima, and Shunan.

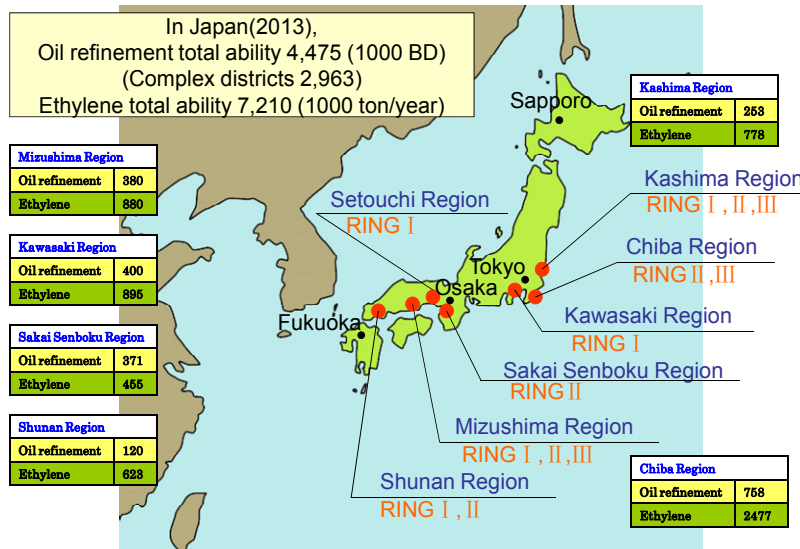

Figure 2 Development of RING 1,2,3 Projects

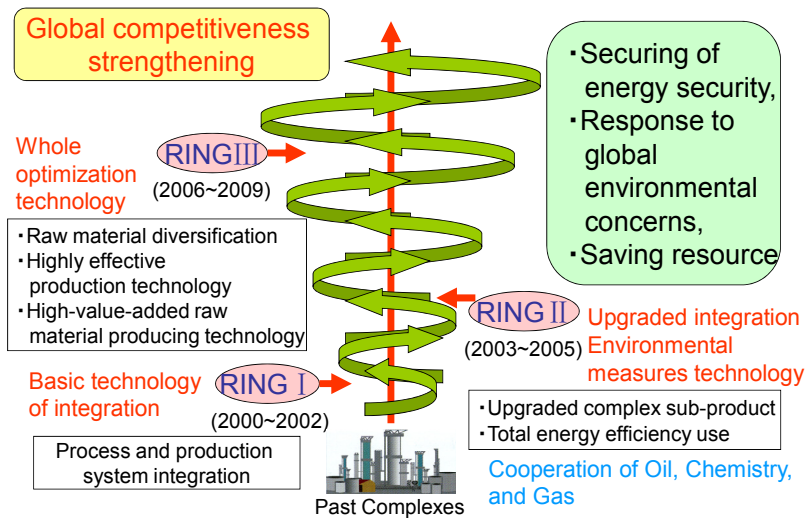

Figure 3 The Spiral-up Innovation in Group Operation

One company perhaps tends to attempt single survival and optimization. Even if it notices the importance of cooperation, the priority level might be low. There are only two choices whether to execute it or not in one enterprise. Therefore, the government needs to put out a subsidy at first as a trigger, and it is necessary to establish the third-party institution in order to give the motivation to business cooperation. It is important to build the organization to adjust common interest. The support of the government for RING projects is a pump-priming policy. And the enterprises have recognized new possibilities in business cooperation. They would begin to mix well with them, and come to analyze a system of production with each other. They would examine construction of system of production and technological development accommodating wasted gas, heat, and energy etc. And profits between enterprises, which one company cannot conceive, would begin to be recognized, and their interest would

spread various contents such as treatment of waste, contribution to the region, joint power generation etc. Innovations have progressed in an upward spiral through cooperation between enterprises beyond the limit of single company business. The new idea of business cooperation has arisen one after another.

3 Economies of Combination

Strengthening cost competitiveness is requested in oil and petrochemical enterprises in Japan. The consolidation and expansion of manufacturing scale, efficiency improvement in manufacturing process, and reduction in cost of manufacturing are more necessary to obtain global competitiveness. To solve the problems, RING was established. The RING project is an attempt of joint operation and business cooperation in oil and petrochemical business. The project assumes current production facilities, capital tie, and business activities. On that assumption, it is necessary for two or more enterprises to cooperate and work on reduction of environmental burdens facing the world. Different from the strategy that one company pursues productivity and efficiency, same kind of effects may be achieved by cooperation between enterprises and different types of business. Whole optimization will be achieved by the system in group operation. And they can implement simultaneously two strategies, Cost Leadership and Product Differentiation.

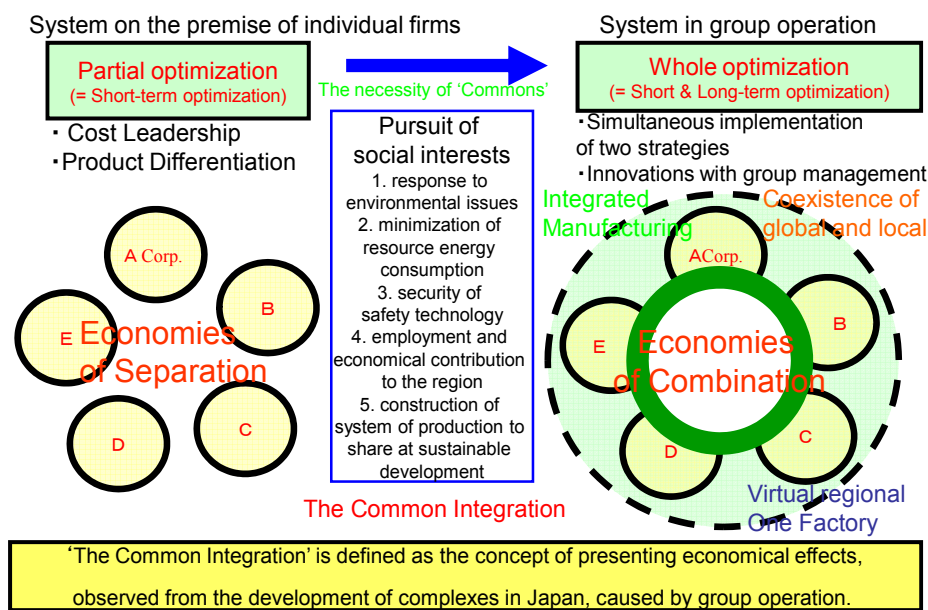

Figure 4 Concepts of the Common Integration

The results of business based on the premise of one company

- Partial optimization and efficiency
- Alternative strategies; Cost Leadership or Product Differentiation

The results of business in cooperation with two or more companies

- Whole optimization and efficiency
- Simultaneous implementation of two strategies
- Pursuit of social interests
- Innovations with group management
- Management of Sustainability

“Kombinat” is a Russian word, means “combination”, and is used instead of “complex” in Japan

Figure 5 Economies of Combination(комбинат)

In addition to economies of scale and economies of scope, some social interests will be pursued.

When collaboration with many enterprises is achieved, ‘commons’ will be necessary for cooperation. Therefore, the aspects to social interest will arise: joint energy use, efficiency improvement, regional contribution, establishment of safety technology, positive commitment to environmental measures, and cooperative treatment of waste etc. And enterprises will pay more attention to practices of social activities: greening of the complex, ownership of joint power generating equipment, security cooperative relationship etc. In this paper, economies of combination is defined as some economic effects which group operation produces; whole optimization and efficiency, simultaneous implementation of two strategies, pursuit of social interests, innovations with group management, management of sustainability. The common integration is defined as the concept of presenting social and economical effects, observed from the development of complexes in Japan, caused by group operation.

4 Conclusion

The RING project began from easy business collaborations. It is said that participating companies had not expected the result to joint operation too much at first. However, as RING projects have advanced, most enterprises have come to notice potentiality in the effect of group operation and business cooperation. The circle of RING extends through RING 1, 2, and 3. The speed of technological development in cooperating businesses has increased with acceleration. Innovations have occurred in an upward spiral. And, as time passes, reduction of CO₂, energy conservation, and environmental measures have been paid attention to, and they have been involved in RING projects. If one company does it by itself, only the optimization for one company would be realized. Actions on these problems would be postponed when thinking from the priority level. However, in group operation and business cooperation, these would be problems to undertake first of all.

The goal of the RING project is to obtain global competitiveness in oil and petrochemical companies. When all technological developments are completed, much of reduction of energy use in oil refinement equipment etc. will be achieved, and it will be expected to increase production efficiency by the best flexibility of raw material and semi-finished products between oil refinery plants and different type of factories. And it is forecasted that they greatly contribute to reduction of CO₂ exhaust. As a result of experimental studies that have been done up to now in RING projects, the amount of CO₂ exhaust reduction is expected to reach 500,000 tons/year or more. In addition, the developed technology will be applied to other domestic industrial complexes, and therefore reduce CO₂ further.

Oil and petrochemical companies in Japan come up with the idea of integrated manufacturing to gain global competitiveness. In addition, this way has various effects and the meanings. Especially, there is an important meaning that this would ease control by market mechanism.

The headquarters one-sidedly draw up neither the business plan nor the production plan. Neither the price nor production might be controlled by an international market. The cooperative relationship by group operation is a method of pursuing for such a new economy. It is the management separating system, though businesses are integrated. Various resources would be used by negotiations through the network of the producer, the consumer, the local government, and the resident, etc. It contains the policy of the overall distribution of various resources, the growth rate, investments, the energy consumption, transportations, and the plans of sustainable development and environmental protection. Definite variables of economic activities are systematically decided by the decision making organizations adapting to the level of district, local, national, and international. Detailed plans are decided at each level based on discretion. In the process of all the discussions, the idea of whole optimization will occupy the center of business plans and policies. As a result, the whole optimization is prior to the partial optimization. And social necessities may decide the plans that what and how much they produce. On competition by individual firm and requests of international market, enterprises will be deprived of the authority to make decisions that what and how much they produce. In pursuing the common integration, the decisions can be regularly exercised. In such a meaning, the regional, joint manufacturing body has the right to make decisions of the investment. It is not a top-down type from the headquarters in each company, but a bottom-up type from the agglomeration of factories in regional zones. In the same way, the price will be set not by decision in headquarters, but the unit cost of production based on inputs from consumers, customer, and regional profit groups etc. However, such a production method doesn't adjust to all industries. This should adjust to the goods, close to the employment and development of regions, such as food, health, medical treatment, medicine manufacture, education, transportation, energy, product necessary for living etc. On the contrary, consumer goods,

luxury goods etc. should be controlled by market mechanism. The joint production of many interests firms seems to require the complicated and troublesome administration and organization. But the scheme of joint business operation would be used, if the form of administration and organization is constructed once. In doing so, actual complication of interests adjustment could be standardized.

Which system would be superior in the cost and time spent on administration and organization? There might be more wasteful spending in system on the premise of individual firms than system in group operation, when individual firms, which are influenced by market, would be aimed at partial optimization. There is no evidence that the system in group operation would spend in the cost and time more than the system on the premise of individual firms.

Construction Organization and Management Based on Virtual Reality System

Xu Jinbo

School of Art & Design, Wuhan University of Technology, Wuhan, P. R. China, 430070

(E-mail: Xujb1203@126.com)

Abstract: Currently, the combination of virtual reality technology and civil engineering construction is becoming increasingly close, and the informatization of its organization and management has been improved significantly. This article discusses the application of virtual reality technology in the control and management of the construction process, as well as in the selection and optimization of the construction scheme. This article also analyses some examples to illustrate that the application of the virtual technology in civil engineering will be even more in-depth and universal. It will turn a new page of the traditional construction management.

Key Words: Virtual Reality; Construction Management; 4D

1 Introduction

Virtual reality is to monitor a three-dimensional virtual world in the aid of a computer where users can feel personally on the scene, and can freely observe any item in the three-dimensional space in time. VR is a comprehensive integrated technology involving computer graphics, interactive technology, sensor technology, artificial intelligence and other fields. It can generate three-dimensional vision, hearing, smell and other feelings through computers. It can involve people through appropriate means in experiencing and interacting in the virtual world naturally (Figure 1).

Figure 1

The technology integrates the latest achievements of the computer graphics (CG) technology, computer simulation technology, artificial intelligence, sensor technology, display technology and the network parallel processing technology. It is a high-tech simulation system generated in the aid of computers, and is a new way through which people can visualize and exchange complex data operations. Compared with the traditional man-machine interface and the popular windows operating, virtual reality has achieved a qualitative leap in terms of technological ideology.

2 Construction Organizations and Management Based on Virtual Reality System

2.1 Application in Control and Management of the Construction Process

Virtual reality is primarily a visualization interface technology that can effectively create a virtual environment (Figure 2). It mainly focuses on two aspects. First, virtual environment can accurately represent the state model of the objects. Second is the visualization and rendering of the environment.

Figure 2

Construction management and control of civil and architectural engineering is a dynamic, complex and integrated process which penetrates throughout the life cycle of each project, in particular those modern large-scale projects which boast large work amount and long duration. It is involved with large capital, materials scheduling, construction machinery, equipment management and the co-ordination of various types of building grades. How to guarantee the quality, schedule and cost of the project, manage its information, and implement the contract effectively is difficult to achieve by usual engineering experiences. The 4D project management information system effectively collects and integrates information of the whole project, and realizes the informatization, integration, visualization and intellectualization in construction management and control. The so-called 4D model takes into account the additional time / cost factors on the basis of architectural CAD three-dimensional (3D) model. The synarticle of this technique is not only a visual medium that enables users to see the graphic simulation of the objects' changing process, but it can also optimize and control the whole vivid changing process. In this way, it will be conducive to the safety of field operations. Chronological simulation of the construction schedule can do a more precise calculation and control of the project's duration, and is conducive to the co-ordination and scheduling of people, materials, and objects, thus realizing the interactive visualization and informatization of the building operations(Figure 3).

Figure 3

2.2 Application in Selection and Optimization of the Construction Plan

The virtual environment created by virtual reality is integrated by the digital model based on the real data. It strictly follows the standards of the project design and requires to establish a realistic three-dimensional scene, thus achieving "representation" of the construction project.

Designing a reasonable construction plan is the core of the construction organization. It includes identifying construction flow and construction program, selecting construction methods and machinery, arranging the construction sequence and so on. In terms of some large projects with complex structure, the choice of the construction plan is a bit difficult, but virtual reality system can allow each branch to conduct virtual construction and demonstration of the construction plan. This provides tremendous convenience to the selection of the construction plan. In this way, many subtle design flaws can easily

be found, thus reducing the irreparable loss and regret caused by half-baked planning, and greatly improving the quality and progress of the construction process.

3 Case Study on Application of Construction Organization and Management Based on Virtual Reality System

3.1 Project Overview

The project is the main building tower of a certain district. The building is 137 meters high and 50 meters wide (the chassis of the annex is 243 meters wide). The project covers a total land area of 601,653 square meters, of which the total construction area occupies 71,690 square meters with 56,225 square meters above ground, 15,465 square meters underground, and 27,012 square meters of sandwiching construction areas. There are 11 floors above ground and 1 basement. The podium building has 1 floor above ground and 1 basement. In terms of the entire project, it has the characteristics of "difficult, high and tight"(Figure 4).

Figure 4

3.2 Organization and Management Based on Virtual Reality System

(1) Selection and Optimization of Construction Plan

The project is divided into the basement, the main structure and the decoration. Among them, the main tower is the most complex in terms of construction sequence and plan selection due to its new and special structure. Through the virtual construction project and a number of demonstrations, a reasonable solution is ultimately determined: in the case of ensuring the progress of the main tower, the construction of podium can be interspersed. The podium will first be constructed to less than two floors. The 25 meters in the middle range, as the hoisting steel structural, transporting and disposal site, will not be constructed temporarily. In terms of arranging the schedule, the main tower's concrete construction and steel construction should keep 3-meter difference in height. The mechanical and electrical engineering piping and equipment construction will be started when the main tower is 50 meters high; interior decoration interspersed when 60 meters high; outdoor decoration started when 70 meters high; after the completion of the main tower, the 22-meter-high skirt floor will be constructed after the removal of the tower crane. The identification of this plan has reduced a lot of time of the construction progress and avoided the transport of equipments, so as to reduce the cost for the project.

(2) The Layout of the Construction Plant

Traditional construction floor plan, drawn in the form of blueprint, cannot give people an intuitive three-dimensional effect. Even in the diagram form of 3D effect, it is not easy to timely reflect the dynamic changes of the site layout when it needs to be modified. In such circumstance, construction layout can be conducted only according to the construction experience. In the virtual reality system, the 3D model of the project's entire existing and proposed buildings, construction equipments, entities in each sites, temporary facilities, warehouse processing plants, pipelines and other entities, both above and below ground, will firstly be established. Then, VRML (virtual reality modeling language) will endow every 3D entity with dynamic properties to realize real-time interaction and timely dynamic changes to form the 4D site model. In 4D site model, the shape and location of each entity can be modified whenever you like(Figure 5). In this way, it has greatly accelerated the speed and quality of program design, improved the efficiency of program design and correction, and saved a large amount of capital.

Figure 5

In the system, through the establishment of a unified entity attribute database, the coordinate position, existing time and equipment model of each entity, including the floor space, storage capacity and other information of the temporary facilities, materials stacked space, materials processing zones, warehouses, living and cultural areas is stored in. The roaming virtual space not only allow people to get an intuitive understanding of the site layout, use the mouse to scan the related information of each entity which provides great convenience in laying out the sites according to the specification, but it can also correct the unreasonable elements by modifying the information in the database. The system can also assist the organization to determine a more reasonable site location, transportation routine and transportation programs according to the normative information and site optimization program stored in the database.

(3) Dynamic Management of the Construction Project

The management of the construction project is fundamental to ensure the schedule, quality and safety of the construction process. Traditional management mainly relies on prior design of the construction organization in arranging material, manpower and equipment relying on governors' rich experience. But it may not be able to meet the actual needs, since in this way, future risks of the project are also only able to be predicted by governors' experience, letting alone the timely reflection of potential risks.

In the virtual reality system, through issuing the multiple optimized and pre-identified virtual construction process and synchronising it with the schedule, governors can watch construction progress that should be achieved at any time whenever they like. Through the information stored in the database, they can comprehend the real-time construction equipments, materials and conditions of the site in order to prepare the relevant materials and facilities in advance, and take a timely and accurate control of the construction progress. By demonstrating virtual construction of future conditions, they can discover the construction problems and safety hazards that may arise in the future in advance, and take a timely control to ensure the safety of personnel and to avoid unnecessary losses. Through presentations, they can also find the inadequacies of the construction program in order to modify them and ensure the quality of the project. Virtual construction demo of the system provides a virtual training for constructors, and allows people to understand the condition of the whole project. Due to its strong interactivity, it can be also used in virtual construction which can greatly enhance the experience of the constructors and to improve engineering efficiency. Virtual reality technology has very broad application prospects in the aspect of project management and construction. Stable database information can be placed in the backstage so that the audience can get real-time access to each technical index. Surrounded by a variety of media information, such as engineering background, tenders profiles, technical data, cross-sectional, electronic maps, sound, images, and animation, by interacting with the core of the virtual technology, the virtue reality technology can demonstrate the navigation and positioning on scene, introduce background information and realize many other useful and convenient functions.

4 Conclusions

Construction organization and management based on the virtual reality system can greatly improve

the efficiency of project management and construction, save its costs, ensure the progress of the schedule, reduce the risk of the project and improve its security. Further development in the application of virtual technology will turn over a new page of the traditional construction and management.

A Study of the Process Quality Control Based on Internal Customer Satisfaction

Shui Xiangdong

Huazhong University of Science and Technology, Wuhan, P.R.China, 430070

(E-mail: shuixiangdonghust@126.com)

Abstract: Edition 2000 ISO 9000 newly defines “Process”, making an abundant denotation of the word “Customer”, thus proving a new way of thinking and new method for quality control in enterprise quality management. Nevertheless, how to use the new thinking mode and method in quality control is paid little attention. In view of this, specific strategies of process quality control in the process of material procurement, manufacturing and employees work in all the departments are discussed.

Key words: Customer Satisfaction; Process; Quality Control; Discuss

1 Introduction

Edition 2000 ISO 9000 Family Quality Control System Standard issued by ISO requires the adoption of “Process” in quality management to control quality. The adoption of term “Process” makes an abundant denotation of “Customer”, including external customer and internal customer, thus proving a new way of thinking for process quality control on the condition of “Customer Satisfaction”. The new thinking mode will change the currently ubiquitous situation “I have to control” to “I must control”. It is no exaggeration to say that it is a revolutionary change of process control method. But unfortunately, though Edition 2000 ISO 9000 Family Quality Control System Standard has been issued for 8 years, many enterprises still use the old operation approach in specific process quality control and few people pay more attention to this new method. This is probably due to a lack of recognition of “Internal Customers” and their satisfaction, and how internal customer is based to conduct process quality control. From Customer Focus, the quality management principle, and based on customer satisfaction, the thesis discussed the strategies of conducting process quality control.

2 Understanding Of “Customer” and Terms Related To “Customer”

2.1 Process

Process is a group of interrelated or interacting activities that can convert input to the output. In China, the term of the process appears early on, but belongs to a general word. Due to the emergency and promotion of ISO9000, this term is gradually into the management field, and become the foundation term of the management. Process can also refer to a method of doing or making something. Procedure is described as the content of process in the past, but we generally choose the process instead of procedure now. The concept of process is very wide, any of a set of interrelated or interacting activities can be identified as a process. The process consists of the input, the implementation of the activities and output the three links. The output of a process is often the input of the other (next) process. The process of all activities of the employees can be grouped into two categories: production or manufacturing process (including procurement process), the work process of departments (including the marketing process). The most important and widespread processes are material procurement process, manufacturing process and the working process of the functional departments.

2.2 Product

Product is the result of the process. The definition of the product is very simple, but it's wide because the definition of process is wide. Product includes four categories: service, software, hardware, processed material. The product can be either one of the above four categories, also can be the composition of the several different types of products. Besides, the same category of products in the different stages has a variety of names, such as the hardware products of the manufacture of the same class, is classified by in process or intermediate products, final products; another example is that the products of R&D department have drawings, parameters, requirements, etc. In the service industry, service itself is a kind of product. The result of the process is good one (expected result) or bad one (unexpected results, such as contaminants). However, the result of process refers to the expected one in the quality management.

2.3 Customer

The customer is the organization or individual that accepts products. If the above three terms are

linked together, the customer can be expressed as follows: the organization or individual which can accept a group of interrelated or interacting activities that can convert input to the output. It's not difficult to find from the statement: due to the wide concept of process and product, the concept of the customer is not just limited to external customer, the organizations or individuals are customers as long as they accept products, it not only contains the customers out of organization, the client, the end user, retailer, beneficiary and purchaser, but also refers to the next process operator within the organization, the next team of the same equipment (i.e., the process, post and personal accept the output of previous process in the production, services and activities), even including all of staff in the same position and in the same work (the staff within the organization are collectively referred to as internal customers hereinafter). Therefore, the concept is very important that customers exist in staff, department, the relevant position, process and even yourself. Enterprises implement the principle of quality management that is "Be focused on customer", not only pay attention to external customers, but also want to pay attention to internal customers; every staff, process, post is not only as a supplier, but also as a customer, firmly establish the concept that "internal customer is the same first", the needs of internal customers should be fully considered and concerned as external customer, in order to satisfy internal customer. Based on this recognition, each process and each link can be controlled in customer-focused aspect, and it also provides a theoretical basis for the organization to conduct quality control in customer-focused aspect.

3 Quality Control of the Process Based on Internal Customer Satisfiof

Modern enterprises conduct quality management, whether apply overall theory of quality management, or establish and organize the system of quality management, an ultimate goal is to satisfy customer. So, if it want to satisfy internal customer in the process quality control, staff should obedience to the idea of internal customer anywhere and anytime which is "the next process is customer", and remember the purpose of "Take the customer as central point" or "Customers First" no matter which position they stay and which procedure they do, and what work they are engaged in, then try their best to conduct their own work and task.

3.1 Quality control in procurement process

Substance (contains equipment, material, fittings, cooperation parts etc.) acquisition process, is the basic process of production and operation of enterprise, the internal customer contain all organizations or staffs work in the procedure of using, management and repair of equipment, and the production of product, the diary work of all departments. If the process control is not right, it will effect directly the management of enterprise, or emerge bad effect to the production and operation and internal customer. For example, using the unqualified equipment, material, component etc, can leave behind permanent hidden danger to the process after and the inherent characteristic of product.

In order to consider the effect of acquisition and the satisfaction of internal customer, completely eradicate unqualified products, the procurement department must be strictly pay attention to procurement procedures in the acquisition process:

First, many substances respond to the need of enterprise, classified according to their quality of processes and the effect of products, are focused managed divided generally into three categories: Class A may bring the direct and significant effect to the process and the quality of products in the use of the process of production and operation; Class B may bring the indirect or more important to the process and the quality of products in the use of the process of production and operation; Class C is general for auxiliary parts and bring general or slight effect to the follow-up process and product quality.

Second, suppliers should be respectively inspected and evaluated according to the classification. For the evaluation of Class A material supplier, it should be on the spot inspected in the operation condition of the system of the quality management, supply situation, the ability of the processing and corrective the quality abnormal of the supply, the ability of delivery on time and quantity, the cost performance of products, the technological development ability and the capacity of providing technical service and its effect, the after-sales service capacity (including service attitude, timeliness and effect), etc. At the same time, also through consulting the material suppliers provide, investigate and know from the supplier's other customers, and compare to the other provided material sample and the trial situation, evaluate the analysis results on a regular of the quality. The evaluation of the Class B and C suppliers don't need investigation on-the-pot, generally through consulting the materials suppliers provide, test and trial the material sample, statistics the results of the regular analysis of the provided material quality, in order to achieve the purpose of control of suppliers. The evaluation of Class B supplier, put forward

by the procurement department Class B supplier evaluation list and related material, or previous Class B material inspection, usage, service, price, etc, send technology, manufacturing, quality, financial and other related department to sign (review) for approval, report to top managers for record; the evaluation of the competence of Class C supplier, put forward by the procurement department Class C supplier evaluation list, send quality, financial (logistics if it is necessary) department to sign for approval, implement after signing by procurement department manager.

Third, choose and determine the qualified supplier. The selection and determination of the purchasing supplier, depends on the results of the above all suppliers quality assurance ability evaluation, and the satisfaction of internal customer, the price, the prestige and other factors. But the satisfaction of internal customer is the focused factors of the selection and determination of the qualified supplier. If the internal customer satisfaction and the supplier quality assurance ability is basic quite, should select more appropriate suppliers in the same material to compare, and finally to adjust, determine supplier (the optimizing of supplier).

3.2 Quality control in production process

A production process is not only an internal customer of the last process, but also a supplier of the next process. This process is mainly controlled in the people, equipment, materials, method, environment and measuring six elements. The above has discussed generally the control of "Material", here no longer give unnecessary details.

3.2.1 Human control in production process

In order to meet the requirements of the process on the people, ensure the production and the quality, the following are necessary in the human management: for manager, it should have certain requirements in the individual qualifications, experience, technology, capacity and the knowledge of quality management, consciousness; for operator, it mainly has specific provision in the operating skills, quality consciousness, etc; the staff engaged in special trades and key process must be certified. At the same time, it must be considered comprehensively in the physical disability, mental activities, error behavior, violate discipline and other aspects, and be careful in selection of staff.

3.2.2 The control of using equipment maintenance in production process

The control of equipment is mainly in two aspects of maintenance and repair.

Based on the idea that the next shift is customer or personal on duty is the customer in another work day, the control of equipment maintenance should be finished in three "should" and six "without" on duty. Three "should" are: the trough should be cleaned; the axis should be oiled and the equipment should be kept its true qualities. Six "without" are: without wiping the equipment won't we leave; without clearing up the work piece won't we leave; without keeping the tools in order won't we leave; without filling in the Shift Book won't we leave; without shutting off the Power Supply won't we leave; without cleaning up the floor won't we leave.

3.2.3 The control of method in production process

The control of method is the control of mainly technical solutions, process flow, process parameters and operating rules, detection means and other technical documents, and is the control of conformity, suitability, adequacy of these documents. In order to ensure the conformity, suitability and adequacy of these documents, the research personnel of enterprise should have a full understanding of internal customer quality, production process, quality, equipment, materials, environmental requirements, design intent and other afferent information before developing documentation. After formulating the documents, review as the procedure and perform as the approval. After distributing documents to related manufacturing procedure, timely trace the conformity, suitability, adequacy of document and satisfaction of internal customer in the process after using. If the document doesn't match the actual situation found in the production process, it should be modified in accordance with the regulated program.

3.2.4 The environmental monitoring in production process

Environmental factors in production process have a significant and direct effect on the product quality. Therefore, in production process, it is necessary to continue to improve and maintain the production environment and operating environment. Based on the satisfaction of internal customer, when in off work or discontinued, downtime, clean production environment and operating environment, and create a well environment to start for others next of yourself. Generally to do a flat (flat ground), two net (net of glass of doors and windows, net of floors and walls) or three clean (ground is clean, glass of doors and windows are clean, equipment is clean).

3.2.5 The production inspection and the control of nonconforming product in production process

In order to be responsible to the internal customers in the subsequent process, there must be strict implementations of "self-test", "cross-test", "special test" (three tests system) and other inspection

systems in production process. After the completion of the inspection, it should be the testing of completion. After the inspection, it can only be transferred to the next process (commonly known as “turn sequence”) for using. Otherwise, it can’t be transferred to “turn sequence”. To prevent the combination, misuse by internal customer in the subsequent process, defective goods should be placed in the designated area, be kept in strict isolation control and identity, no person shall change in the area of nonconforming product and remove the identification of nonconforming product. After maintenance or repairing of the nonconforming product, it must be rechecked and record, qualified and available to order. Otherwise, not “turn sequence”.

3.3 The quality control of working process in various departments of the enterprise

As mentioned above, in the same position, San Zhang and Si Li tomorrow respectively is San Zhang and Si Li today; work and activities between departments are often mutual input and output, and are reciprocal causation, and also are the each other’s internal customers. The control of department personnel work quality in process, mainly contains not something goes wrong, shuffle, transfer contradiction; “do today until tomorrow”, make every job reach “four satisfactions”: their own satisfaction, higher satisfaction, colleague satisfaction, department related satisfaction. To do this, the staff in addition to being educated in the sense of quality about internal customer satisfaction, “quality in my hands”, still be required to do every concrete work in accordance with the idea of PDCA, namely all have plan, all have implemented and treated, everyone often have introspection, and not left problems and regrets to others, not left contradictory to other relevant departments.

4 Conclusions

The customer satisfaction-based process quality control mode is a brand new quality management mode. It will change the passive “I have to control” situation that was and even today existing in enterprise quality management, and will turn the concept of total control management, i.e. “total involvement, entire process, full range, multi-method control” into reality. There are many “activities” in an organization, and the recognition processes will involve no less than the “process” stated above. Several important processes are discussed in the thesis simply to open the subject for discussion.

A Study on the Evolution of Knowledge Management in Enterprise Production Process

Wang Sipeng

Huazhong University of Science and Technology, Wuhan, P.R.China, 430070

(E-mail: wangsipenghust@126.com)

Abstract: This paper discusses the process of evolutionary stages about knowledge management in enterprise production, the influence of the two important factors market and technology on the enterprise knowledge management. In enterprise production, market and technology is the power for the development of the enterprise production. The essence of market and technical is to show the basic problem of what enterprise product and how enterprise to produce. The development and evolution of knowledge management is unfolded around the market and technology. The evolution of the knowledge management process through three stages that the product orientation, market orientation and knowledge orientation.

Key words: Knowledge management; Knowledge; Market; Technology; Enterprise production

1 Introduction

Enterprise is an independent economic organization, but this kind of independence does not mean that enterprise develops independently, the comprehensive effect of the social environment play an important role in the development of the enterprise. The development of the enterprise production has its inherent laws, which is the inevitable result of social development. In social life, people will produce some material needs along with the progress of civilization ,and then hope to have such a product to meet demand. So the enterprise produce products to meet the demand of people. First, the enterprise must be clear about that what products can satisfy people's needs; Second, the enterprise should consider that what method will be used to produce the product. These two problems, one is what to produce, one is how to produce, which is actually the two important aspects: market and technology that enterprise needs to face. The power for the development of the enterprise production comes from these two factors: market and technology. Therefore, in the process of production, the market and technology's problem is the basic problem. The development of knowledge management unfolded around these two problems.

2 The Evolution of The Knowledge Management Process

The evolution of the knowledge management in the enterprise production experienced a process from scratch. Of course, this does not mean that knowledge in enterprise production is also out of nowhere. In fact, knowledge is already exists in enterprises ,which starts from the enterprise as a economic entity, knowledge always affects the development of the enterprise^[1].What knowledge management do is just that: explore the knowledge that uncovered in the enterprise, change the influence of knowledge from concealment to obvious, the enterprise accept knowledge passively into enterprise seek knowledge initiativly, enterprise's knowledge can be used more effectively through the knowledge management^[2]. From the simple to the complex, from discovery to application, knowledge management gradually play a role in enterprise production. The evolution of the knowledge management can be divided into three stages. Each stage oriented a typical production as the goal. The first stage is the product oriented bud stage, the second stage is the market oriented development period, the third stage is the knowledge oriented mature stage. From figure 1, we can see three stages stepped up step by step, the prior stage is the foundation of the backward stage, the backward stage is deepening of development of the prior stage.

Figure 1 The evolution of Knowledge Management in the Enterprise Production

The above is the analysis of evolution phase of enterprise knowledge management in the production; the following will discuss the two important factors: market and technology of development of knowledge management.

3 Market Factors

Market is one of the important factors that influence the enterprise production. The enterprise production is inextricably linked with the market demand. Enterprises should make clear above all strategic positioning before the production. That is clearing what market demand the enterprise can meet, and what product the enterprise should provide to the market. Strategic positioning is the goal of the enterprise production.

Market demand pulls enterprise production, at the same time the enterprise management theory also become more and more perfect timely following the production practice. Such as automobile manufacturing, in the early 20th century, the way of the car production has characteristics that includes a single piece of small quantities, high cost, low productivity. High cost and low productivity, make the market's car price on a high level, and influence the further spread of the car. The requirements of the market for cars is cheap bulk, which requires the production of automotive must meet the low-cost high-efficiency. America's Ford invented the assembly line production, make the machine and the operating personnel arranged by the detailed planning of the sequence of operations. In the moving assembly line, the production of a car time is much shorter, the production cost reduced, the output also increased. Pipelined mode of production meet the demand of the market, and get a great deal of success, opened a modern production sequence Curtain. Pipeline, as a new mode of production, promote the development of enterprise management theory. After World War II, the market demand became more complex and demanding, in the market, with vehicle production increased, demand for cars is not only the number, the car's performance, quality, price, delivery time are all factors must be considered. Goal of enterprise competition in the market began to expand from the production to more areas. Toyota-time (JIT) production can providing customers with products in accordance with the needs of customers, in the time required. This mode of production soon helps Toyota to gain an advantage in the market. The market demand for cars has changed; the enterprise production will make corresponding reaction. Only follow closely the market changes, the enterprise will not washed out by the market. And the enterprise production change will bring the corresponding development of production theory.

Enterprise products' market behavior is in fact the sales activities. The traditional mode of enterprise production has effects on sales, this is the so-called product orientation, and namely production decides to sell. In knowledge management, market factors gradually get attention, sales is counterproductive to production, this is the so-called market orientation, is also called sales affect production. Use knowledge management in the enterprise production, reversed the traditional way, through reverse thinking, bold innovation, struck to the nature of the core problem. Production target, is product on the appearance, but the essence is making the production of products sold. In other words, the production goal is to be able to product the products that can be sold, rather than the production simply. Only the production taking market factors of production into account is closer to essential production.

4 Technical Factors

The technology is also an important factor to affect the production. Especially in knowledge management, the application of the technology indeed promote the development of knowledge management^[3]. When the enterprise clear strategic positioning, clear what products to product, then it is necessary to consider how to product. The enterprise need to consider use what forms of production organization and technical means to manufacture products, to achieve strategic objectives. Technology is the important factor to promote the development of production.

The production technology includes two aspects: Manufacturing technology and management technology. Manufacturing technology is the operation type, is the direct manufacture technical means of the product. Management technology is a concept model, is the arrangements of production organization forms. Manufacturing technology focus on improvement of operational microscopic level, management technology focus on the change of macroscopic level idea. The two technologies are all production need. For example, in the Ford's assembly line production, machines and personnel in arrangement in accordance with the sequence of operations. Production uninterrupted in line, which need two premise condition to ensure: the parts are standard and can be switched; Production line producted according to the time, TAKT time sequence can plan. The first condition requires manufacturing techniques to

support. When machine tools' machining accuracy has reached a certain level, can make machining parts in certain permissible error range, thus the exchange can be realized. The second condition requires the management technology to meet.

Work quota and standardization are part of Taylor's scientific management theory, that provides theoretical support for the Ford assembly line production. In support of manufacturing technology and management techniques, production lines become more and more perfect in practice. Manufacturing technology and management techniques jointly promote the development of the mode of production.

Influence of technology can be seen from the enterprise production changes direction. As shown in Figure 2, three thumbnail, A, B, C stand for each direction of the development of the production. Small box in the figure indicates the basic elements of production or strength. The combination of the small box says the development of the production.

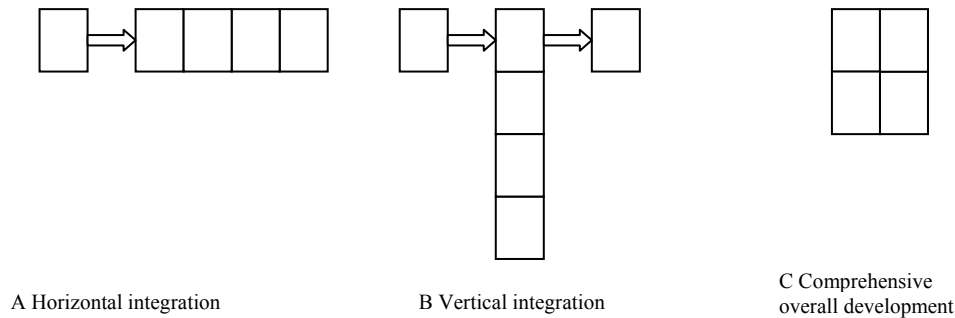

Figure 2 The Direction of Development of the Production

A figure shows the development of horizontal integration. Let a small square on behalf of the enterprise's basic elements, Let a small square on behalf of the enterprise's basic elements, the development of enterprise is the horizontal expand. Transverse integration said enterprise expand the existing similar resources, such as machinery, plant, personnel, etc. In the initial stage of a enterprise, its size restricts the production. Under the product guide, produce more products, the more income. Therefore, the enterprise larger, more machines, factory building, personnel, can have more yield, get more income. In the transverse integration development, small businesses develop into big business mean copying and increasing the small business's machines, factories and other resources, which is a kind of the fastest and easiest way to be effective and implement in production development initial period. Enterprise transverse integration's growth direction indicates that idea of the enterprise development is still in a traditional old framework, except a slight change of scale.

B figure shows the development of vertical integration, Small square shows that essential element of enterprise production is the longitudinal accumulated. That is to say, enterprise production extends to both suppliers and distributors directions, longitudinal extended enterprise production. Enterprise can not only pay attention to production, production should not only for production, only expand the look to two direction before and after the production, production can be more in line with the actual market. Vertical integration is the choice of market orientation. Vertical integration is the choice of market orientation. Only by the way of adding machine, expand production, cannot meet the enterprise's demand of market, and can't win competitive advantages in the market. If combine the production and supply together, the products will be more competitive. The development of the enterprise vertical integration shows that the enterprise began to break the traditional framework, change to close the nature of the market competition direction.

C figure shows the comprehensive overall development, Small Square on behalf of the enterprise strength, this small square together in order to produce force, promote enterprise development together. The comprehensive development is that whole enterprise mine internal and external resources fully, integrate resources and use of resources effectively. The resources including the knowledge resources. The integration of resources is to generate technical force, or is to use the power of technology to let the resources in the best cases when get used. This development process is the process of knowledge management. Enterprise's advantages of production scale, production number, the change of the amount have reached a certain threshold, difficult to have great change. So the changes of enterprises need a qualitative change so as to attain a higher level. The qualitative change's realizing should rely on technology. Whether manufacturing technology or management technology, the transformation in the enterprise is all innovation. Technology

plays a leading role in innovation. With the knowledge management, the enterprise production technology can produce force, promote enterprise production development.

From horizontal integration to vertical integration, and then to the development of comprehensive whole, this process is a typical enterprise development. When a small businesses trying to develop itself, they will general consider buying more machine equipment so as to increase production. The scale of the enterprise is expanding in a replication of similar resources transverse integration process. When the size of the enterprise are big enough, the enterprise will also hope takes supply and distribution process into the enterprise internal account, then the enterprise began the development of vertical integration. The enterprise mining internal and external resources, use technology to produce innovation then make the enterprise produce essential change^[4]. The essential change comes from the enterprise knowledge management.

The development of production, after transverse and longitudinal later, step on a knowledge management way depends on technology innovation. From the production process of development view, the role of technology in the production has two levels: passive and active. Passive refers to that is the objective environment let the technology play a role in production. When the enterprise have obtained development in the transverse and longitudinal aspects, and need to find a new direction, the enterprise will begin to pay close attention to the power of technology. In the enterprises' transverse and longitudinal development process, enterprise also has understanding for technology, but this understanding did not deep in comprehensive whole, the function of technology also is not obvious. Technology is pushed to the center of the stage of the enterprise in passive, the developing technology is gradually put effect actively to the enterprise. Knowledge management is the performance that the technology take the initiative to change enterprise.

It is a change that technology change enterprise passively to change enterprise actively Even in the enterprise's horizontal and vertical development, the enterprise also has active application technology behavior. However, after all, in the transverse and longitudinal development, enterprise's core development power is not the technology. Technologies truly become the core of enterprise development when in the comprehensive overall development stage. At this time, knowledge management gradually matures because the role of technology highlights.

5 Conclusion

The evolution of knowledge management in the enterprise production has experienced three stages of the product-oriented, market-oriented and knowledge-oriented. From a product-oriented infancy to market-oriented development stage, until the mature stage of the knowledge-driven, this three stage reflecting the expansion of knowledge in breadth and depth. From the enterprise internal to the enterprise external, from the current to the future, knowledge management respectively extension in space and time. The market is an important factor in the enterprise production, the market also has an important role in guiding the development of knowledge management. Market demand drive knowledge management to seek new solutions actively. Technology promotes the development of knowledge management and knowledge management promotes technology development, these two processes is a complementary process. Technology provides the basis for achieving some of the ideas of the knowledge management. Whether the evolutionary stages of the knowledge management, or the role of market and technology factors, shows the market and technology play an important influential role deep in the enterprise production process, market and technology also pointed out the development direction of knowledge management in enterprise production.

Early-Warning Study of Heavy Deficit Based on Financial and Non-Financial Characteristics in Listed Companies of China

Gong Haifang, Li Hongsong

School of Management, Wuhan University of Science and Technology, Wuhan, P.R. China, 430081
(E-mail:120062435@qq.com, lhs680904@163.com)

Abstract: 42 heavy deficit companies and 42 non-deficit companies from listed companies in Shanghai & Shenzhen Stock Exchange of China are selected as samples for study, and non-financial variables such as corporation governance, etc. are introduced on the basis of the financial data. Then this paper use principal components analysis to find out the cause of companies loss, and binary *Logit* model is established to predict the probability of heavy deficit. The result reveals that five factors are of significance statistically to predict the probability of heavy deficit.

Key words: Heavy deficit; Financial indicators; Non-financial variables; Prediction

1 Introduction

The latest statistics from China Securities Regulatory Commission show that the number of domestic listed companies by 2012 is estimated to be 178 times the amount of 1991. And the total market capitalization of Shanghai & Shenzhen Stock Exchange of China reaches 23.04 trillion ranking second in the world. But in the face of market competition and challenges brought about by the expansion of securities market, the performance of listed company operating in China is not optimistic. The most prominent problem is the range and amount of deficit has increased year by year, and many companies even have huge deficit, which would make company run into trouble and erode benefit of investors and other stakeholders in different degree, and even waste social resource and affect the development of securities markets. According to research, the company's financial crisis or heavy deficit is not formed overnight, but during a long process of incubation, development and eruption. Therefore it's useful to establish early-warning model monitoring its financial condition on the basis of analyzing financial and non-financial characteristics of listed companies in China for stakeholders and companies themselves.

Throughout the results of previous researches, it's found that the Euramerican researches mainly focus on insolvent, bankrupt and defaulted financial predicament, and their early-warning. The typical model are Z-Score (Altman, 1968)^[1] and upgraded ZETA (Altman and Hardeman, 1977)^[2], which updated the financial indicators for interest protection multiples, cash flow ratio, etc. and they are reference indexes for later researches. For example, Roberto and Nicolas (Roberto Mariano Garcia and Nicolas Emanuel Manti 2010)^[3] used some indicators including them for financial distress early-warning. Comparatively speaking, most of the scholars in China focus on characteristics of ST company, like principal component analysis (Yuan Kanglai, 2010)^[4] is constructed with financial indicators. In recent years, non-financial indicators are taken in for valid and precise estimates. Non-financial information (Wang Yanning, 2012)^[5] is introduced to forecast the financial potential risk from different perspectives. And some scholars begin to pay attention to problems of financial crisis caused by the listed company deficit, but the research needs to be further completed and developed. Based on the relatively former studies, this paper makes a special research on the field of deficit early-warning through summarizing its financial and non-financial characteristics to enrich the relative theories and provide some reasonable suggestions for practice.

2 Definition and Influential Factors of Heavy Deficit

Some researchers believe that deficit is a special state of company financial distress, as well as default of preferred stock dividend and other debts, insolvency and liquidation. And some scholars put forward three stages of company failure, which are financial crisis, financial imbalance and bankruptcy. The domestic research use exceeding a certain limit losses to define for heavy deficit or some indicators as definition standard. In this paper, return on net assets less than the first quartile (-17%) of deficit companies is used to define heavy deficit, which turns out a unified criterion of classification and offers possibility of distinguishing and contrast for different companies in different scale, industry or background.

In the actual case, it's found that many listed companies get a sudden and unexpected big loss, and even accumulated profits are not worth one big loss. That is mainly because the listed company itself has some problem, expect for restriction and influence of specific macro environment. There are 6 internal factors mainly affecting company deficit. First, corporate governance and ownership structure is not perfect, which distort the division of responsibility and allocation of right, and restrict business development. Second, seeking for scale economic and financial lever benefit blindly results in irrational and imbalance structure of capital and cash flow. Third, the company is not performing well due to low management level and administrators' lack of honesty and credit. Forth, the main business is weak for support profit levels because of pursuing short term or ancillary profit. Fifth, blind expansion and excessive investment in the process of diversification strategy increase managerial risk and cost. Sixth, there are so many bad debts that the problem of cash turnover appears on blindly seeking for sales, poor search and verification for customers' credit.

3 Research Hypothesis

3.1 Financial factor

The financial condition of enterprises mainly depends on the solvency, operating, profitability and development ability in modern management theory, so most domestic studies are using this multiple financial index system to analyze and judge of financial affairs state of a company. In general, the stronger a company's solvency ability is, the more secure. And operating reflects the level of the ability of corporate business management and asset profits, therefor the stronger the better. Profitability is important to ensure capital appreciation, so stronger profitability explains the investment and operating decisions more effectively. Development ability mainly considers the possibility of future company appreciation, but blind expansion and excessive investment would lead to other problems. So this paper presents the hypothesis that the solvency, operating, profitability and development ability have negative correlation to the probability of company heavy deficit considering its particularity.

3.2 Non-financial factor

Non-financial factors should also be considered in the research of company heavy deficit affecting factors and early-warning model in view of imperfection of external market and internal governance environment. First, corporate governance and equity structure are important factors for strategy development, decision-making, operation and management, which have a great relationship with whether or not directors' role of supervision can develop effectively. In this paper managerial shares ratio and floating shares ratio are chosen as indicators standing for corporate governance and equity structure respectively. Second, cost of equity agency measures whether every penny spends valuable and dividend payout can monitor if there is something wrong with the cash flow and modified profit. Third, as the credit assurance organizations have confronted with many problems in china, outward guarantee behavior of listed companies, in particular, related parties guarantee contains huge financial risk, and becomes the primary method of control shareholders encroaching on company property. Therefore the hypothesis is presented that managerial shares ratio, floating shares ratio and dividend payout have negative correlation to the probability of company heavy deficit, and cost of equity agency and outward guarantee ratio have positive correlation.

To sum up, in order to describe and forecast objectively and accurately, financial and non-financial indicators should be comprehensively considered on the study of listed companies, and an early-warning model is established using non-financial information and financial information in this paper.

4 Empirical Analysis

4.1 Data sources and sample selection

According to the definition of heavy deficit in the previous section, this paper selects 42 heavy deficit companies, the first quartile (-17%) of deficit companies, and non-deficit companies as the matched sample from listed companies in Shanghai & Shenzhen Stock Exchange for study. Two sample groups are in the same industry and have similar size of capital. Without no-matching and low-margin companies, there are 84 samples.

4.2 Indicators and variables selection

There are 14 financial indicators selected referring to indicators with significant effect in previous studies, and 5 non-financial variables selected. Detail information is in Table 1 as bellow.

Table 1 List of Financial Indicators and Non-Financial Variables

Financial Indicators			
Solvency	1	Current ratio(X_1)	= current assets/current liabilities
	2	Cash flow ratio(X_2)	= net operating cash flowing/current liabilities
	3	Debt ratio(X_3)	= total liabilities/total assets*100%
	4	Tangible debt ratio(X_4)	= total liabilities/(total equity- net intangible assets)
Operating	5	Accounts receivable turnover ratio(X_5)	= sales/accountant receivable
	6	Inventory turnover ratio(X_6)	= sales/inventory
	7	Total assets turnover ratio(X_7)	= sales/total assets
	8	Assets operating cash flow turnover ratio(X_8)	= net operating cash flowing/total assets
Profitability	9	Profit on total assets(X_9)	= profit before tax/total assets*100%
	10	Operating profit margin(X_{10})	= operating profits/operating revenue*100%
	11	Major business profit margin(X_{11})	= major business profit/prime operating revenue*100%
Development	12	Growth rate of net assets(X_{12})	= Y-o-Y change of net assets/net assets in last period*100%
	13	Growth rate of profit(X_{13})	= Y-o-Y change of total profit/total profit in last period*100%
	14	Growth rate of major business income(X_{14})	=Y-o-Y change of major business income/major business income in last period*100%
Non-financial Variables			
Governance	15	Managerial shares ratio(K_1)	=managerial shares/total shares
Equity	16	Floating shares ratio(K_2)	=floating shares without sales limit/total shares
Agency	17	Cost of equity agency(K_3)	=general and administrative expenses/total assets
Dividend	18	Dividend payout ratio(K_4)	=cash dividend per share/earning per share
Guarantee	19	Outward guarantee ratio(K_5)	=total amount of outward guarantee in last period/total assets in this period

4.3 Index screening and data processing

4.3.1 Mean value test method

In order to effectively distinguish between deficit and non-deficit companies, mean value t-test is used to analyze the data of financial indicators and non-financial variables. The data is divided into two groups. Group one is from deficit companies, recorded as 1, and the other one is from non-deficit companies which is recorded as 0. Null hypothesis is that there are significant differences between the two groups. When Sig. (2-tailed) is less than 0.05 in 95% confidence level, null hypothesis is accepted. There are 12 indexes passing the test by SPSS 19.0, including X_1 , X_2 , X_3 , X_8 , X_9 , X_{10} , X_{11} , X_{12} , X_{13} , X_{14} , K_4 and K_5 .

4.3.2 Principal components analysis

For improving multicollinearity, principal components analysis is used to find out common factors from the 12 standardized indexes, and the factor scores enter the binary *Logit* model as the independent variables. The following table is eigenvalue and contribution rate for each factor.

Table 2 Total Variance Explained

Component	Initial Eigenvalues			Extraction Sums of Squared Loadings			Rotation Sums id Squared Loadings		
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %
1	2.857	23.807	23.807	2.857	23.807	23.807	1.887	15.723	15.723
2	1.641	13.673	37.479	1.641	13.673	37.479	1.811	15.094	30.816
3	1.492	12.431	49.910	1.492	12.431	49.910	1.476	12.304	43.120
4	1.111	9.261	59.171	1.111	9.261	59.171	1.126	9.380	52.500
5	1.036	8.634	67.805	1.036	8.634	67.805	1.121	9.340	61.840
6	.905	7.542	75.347	.905	7.542	75.347	1.044	8.697	70.536
7	.753	6.276	81.622	.753	6.276	81.622	1.028	8.568	79.104
8	.723	6.029	87.652	.723	6.029	87.652	1.026	8.548	87.652

From table 2, it's found that the cumulative contribution rate of the eight factors reaches 87.652%, and that means the eight factors contain so much information of original 87.652% that they can replace the original indexes. According to the rotated component matrix, which abbreviates with length of be confined to, six results are summarized. First, the absolute values of X₂ and X₈ are high in F₁ which is defined as the main factor of the listed company solvency ability and operation ability. Second F₂ is defined as the main factor of the listed company solvency ability including high absolute values of X₁ and X₃. Third, the absolute values of X₁₅, X₁₄ and X₁₃ are high in F₃, F₇ and F₈ which are defined as the main factor of the listed company development ability. Forth, F₄ is defined as the main factor of the listed company dividend payout including high absolute values of K₄. Fifth, the absolute value of X₉ is high in F₅ which is defined as the main factor of the listed company profitability ability. Sixth, F₆ is defined as the main factor of the listed company outward guarantee including high absolute values of K₅. So the above 8 factors reflect the the financial condition and operating status of heavy deficit listed company from different aspects.

After these factors economic significance clear, the linear expression of each factor on the original index is established on the basis of component score coefficient matrix and the factor scores of each sample are calculated by SPSS 19.0. They are FS1, FS2, FS3, FS4, FS5, FS6, FS7 and FS8, as the independent variables in early-warning model.

Table 3 Component Score Coefficient Matrix

	1	2	3	4	5	6	7	8
Current ratio(X ₁)	-.113	.564	.012	-.128	-.050	.020	-.121	.138
Cash flow ratio(X ₂)	.415	.163	-.130	-.078	-.043	-.076	-.014	.076
Debt ratio(X ₃)	.087	-.474	.009	-.114	-.006	-.049	-.028	.123
Assets operating cash flow turnover ratio(X ₈)	.581	-.185	-.114	-.023	-.003	.021	.021	-.033
Profit on total assets(X ₉)	-.047	-.008	-.166	-.111	.988	.113	-.065	.058
Operating profit margin(X ₁₀)	.192	-.168	.235	.171	.227	-.150	-.102	-.062
Major business profit margin(X ₁₁)	.103	.059	.375	.253	-.115	.196	.130	-.096
Growth rate of net assets(X ₁₂)	-.007	.025	-.011	.043	.039	.064	-.008	.965
Growth rate of profit(X ₁₃)	.011	-.065	-.048	-.077	-.075	-.013	.996	-.004
Growth rate of major business income(X ₁₄)	-.230	.042	.780	-.214	-.189	.080	-.055	.056
Dividend payout ratio(K ₄)	-.027	-.010	-.072	.857	-.070	-.039	-.076	.059
Outward guarantee ratio(K ₅)	-.016	.034	.095	-.020	.106	.989	-.014	.058

4.4 Model building and empirical results

4.4.1 Model building

Whether company has heavy deficit in 2012 is a categorical variable, so binary *Logit Regression* model can be used to identify the influence factors, which has some advantages compared with *Linear Regression* model. First, it does not require variables to meet the normal distribution. Second, more explanatory variables can be chosen to enhance the prediction accuracy of the model. The binary *Logit* model is used in this paper as followed.

$$P = \frac{e^{a + \sum_{i=1}^m x_i b_i}}{1 + e^{a + \sum_{i=1}^m x_i b_i}} \quad (1)$$

Above model in, *P* denotes the probability of heavy deficit depending on independent variable *X_i* (*i*=1, 2, ..., *m*). When heavy deficit is happened, *P* is one, otherwise is zero. And *a*, *b_i* (*i*=1, 2, ..., *m*) are on behalf of estimated parameters. Economic significance of this model is that the probability of heavy deficit can be measured by a set of descriptive variables and regarded as chance variable estimated.

4.4.2 Regression results and discussion

This paper uses SPSS 19.0 to estimate regression parameters of *Logit* model, with forward-conditional method eliminating variables. Through 24 iterations, the final statistical variables turn out FS1, FS3, FS5, FS7 and FS8 as followed.

Table 4 Variables in the Equation

	B	S.E.	Wals	Df	Sig.	Exp (B)	5.0% C.I. for EXP(B)	
							Lower	Upper
FS1	-2.132	1.160	3.379	1	.066	.119	.012	1.151
FS2	-2.235	1.447	2.387	1	.122	.107	.006	1.823
FS3	-2.484	1.373	3.273	1	.070	.083	.006	1.230
FS4	-4.582	3.199	2.051	1	.152	.010	.000	5.413
FS5	-2.732	1.296	4.446	1	.035	.065	.005	.825
FS7	-6.893	3.107	4.923	1	.027	.001	.000	.448
FS8	-11.573	5.852	3.911	1	.048	.000	.000	.902
Constant	-.416	1.230	.115	1	.735	.659		

Assessing fit. From table 5, it' found that -2log likelihood changes from 104.143 to 20.858 and Nagel kerke R² increases from 0.182 to 0.906, which means fit of the model is great, after 7 times of regression analysis.

Table 5 Model Summary

Step	-2log likelihood	Cox & Snell R Square	Nagel kerke R Square
1	104.143 ^a	.136	.182
2	88.073 ^b	.287	.382
3	80.106 ^b	.351	.468
4	65.087 ^b	.457	.610
5	51.476 ^c	.539	.718
6	37.855 ^d	.608	.810
7	20.858 ^e	.680	.906

The results show that FS5, FS7 and FS8 are significant in 95% confidence level, as well as FS1, FS3 in 90% confidence level. As mentioned before, FS1, FS3, FS5, FS7 and FS8 are scores of F₁, F₃, F₅, F₇ and F₈. F₁ is mainly composed of X₂ and X₈, which interprets solvency ability and operation ability. And F₅ is mainly composed of X₉ and defined as the main factor of the listed company profitability ability. F₃, F₇ and F₈ are mainly composed of X₁₅, X₁₄ and X₁₃, which interprets development ability. It's proved that these indictors significantly predict heavy deficit, and explanatory variables are all negative consistent with priori symbol. All the factors are based on the positive index extraction, which means the higher score, the lower probability of heavy deficit in the next year. FS2, FS4 and FS6 can't pass the test in 90% confidence level. So the early-warning model is established as followed.

$$P = \frac{e^{-0.416-2.132FS1-2.484FS3-2.732FS5-6.893FS7-11.573FS8}}{1 + e^{-0.416-2.132FS1-2.484FS3-2.732FS5-6.893FS7-11.573FS8}} \tag{1}$$

4.4.3 Predictive capability analysis

This study is based on 1:1 pairing, so prediction threshold values 0.5 taken into antecedent prediction model to inspect original data. If the P value is greater than 0.5, then determine heavy deficit of these samples, otherwise un-deficit. Table bellowed is the result.

Table 6 Classification Table

Observed		0 Un-deficit	1 Heavy deficit	Percentage Correct
Financial Status	0 Un-deficit(n=42)	40	2	95.2
	1 Heavy deficit(n=42)	4	38	90.5
Overall Percentage				92.9

It's showed there are only 2 un-deficit companies and 4 deficit companies determined inconsistent with the facts. And the overall percentage reaches 92.9%, which means predictive model is appropriate.

5 Conclusions

Through empirical research, there are three results. First, current ratio, cash flow ratio, debt ratio, assets operating cash flow turnover ratio, profit on total assets, operating profit margin, major business profit margin, growth rate of net assets, growth rate of profit, growth rate of major business income, dividend payout ratio and outward guarantee ratio have significant differences between heavy deficit and non-deficit companies. Second, the factors on behalf of solvency, operating, profitability and development ability have negative correlation to the probability of company heavy deficit. And they are mainly reflected in cash flow ratio, assets operating cash flow turnover ratio, profit on total assets, growth rate of major business income, growth rate of profit and growth rate of net assets. Therefore, constructing a reasonable capital structure to determine the optimal scale of assets, and developing the main business and controlling cost, at the same time accelerating the turnover of assets and improving cash management are all good methods to realize profit growth and avoid heavy deficit for listed companies.

As for the limitation and shortcomings of this paper, to a certain extent the conclusion of the paper would be affected by the cross-section data of 2012. Although the influence of non-financial variables are taken into account, the differences of the 3 indicators between heavy deficit and non-deficit companies are not obvious, and further research is not made to get to the bottom of the reason. In the future study it should be improved.

Abstract: In order to make the analysis of information system in Chinese banks' internal management, confirmatory factor analysis (CFA) is used in this paper. By system design, model validation, data collection and certification result, the CFA can effectively conduct empirical research on information system in Chinese banks' internal management. For illustration, the collected copies are 90, and the effective rate of collection is 90%, which has satisfied the requirement that the questionnaire returns-ratio is not lower than 20% in the data investigation. The empirical results show that most factor loading values are relatively high, and are significant. Therefore, in the implementation process of Chinese banking information system internal management, the subject of internal control functions have been effectively implemented and achieved significant results. Furthermore, the role clarity needs to be further strengthened, and bank information systems functions should be clear to enhance the binding strength. Finally, test results of this study can provide realistic and theoretical references for deep implementation for information system internal management.

Key words: Information system; Internal management; Confirmatory factor analysis (CFA); PDCA circulation

1 Introduction

Informationization strategy is a fundamental strategy of Chinese banking industry. It is an effective means to promote the development of banking and is the nature demand of the development of modern commercial banks. Banking is one of the industries which have most effective application of information technology. The improvement of information technology has greatly changed the operation mode of modern commercial banks. Banking is a typical information management industry which provides a natural application space for the information technology^[1]. Banking operations informationization has become the dominant way of banking operations^[2].

In the two decades, Chinese banking industry achieved a great success in financial informationization establishment, which accelerated the transformation from traditional banks to modern banks and enhanced the international competitiveness of Chinese banks. At present, Chinese banking information technology has entered the stage of stable development. At this stage the banking industry generally has entire information system facilities and completes the upgrading of traditional business process by information technology. The function of information technology can be fulfilled steadily. Infrastructure investment has been no longer the focus of banking informationization establishment. Business process reengineering has become a top priority of the banking informationization development.

However, information technology operations have not only brought significant performances of banking operation, but also sped up the banking operation uncertainty^[3]. Particular in the steady development stage of the banking information system, this uncertainty greatly grows and involves every aspect of banking operation, which increased risks faced by banking operation. One hand, financial informationization changed the traditional working way of the banking industry to realize automation of business processes, electronic service delivery, management informationization and decision-making scientific. So, it can provide customers with fast and convenient services and greatly improve the banking business performance. On the other hand, the informationization development has made some degree of uncertainty to the banking business operation. Informationization establishment has led the banking technologic risk, and thus reduced the banking operation efficiency in appropriate time and space.

In recent years, operational risks caused by information technology show multiple features

* This paper is supported by NSF (No.70773001) and Bid Project "Xinjiang SME Internal Control Issues". The project is from Humanities and Social Sciences Key Research Base in Xinjiang Normal University-Enterprise Development Research Center of Xinjiang.

within Chinese banking internal system. Among them, computer crime is a typical risk form which has caused high concern of Chinese banking internal control administrations. Computer crime refers to unscrupulous stuff with the purpose of illegally obtaining money by using computer programs and loopholes in management work to embezzle, steal, swindle and divert the huge amount of money from banks, which is a criminal activity brings enormous economic losses to the state and the banking sector. The perpetrators take computer physical security, software security and data security weaknesses as the main targets, illegal landing, modifying data and stealing information to realize the criminal purposes^[4]. The common means of computer crime includes forging bankbook and watermark to defraud deposit, illegally logging on the computer system and modifying the account, stealing the depositor's information and breaking the depositor's code and grafting.

Therefore, the implementation of information system internal control has become an urgent demand of banking informationization establishment. The internal control is a basic function of banking. However, in the information technology environment, the goal and task of this management functions will gradually turn into the direction of information system control. Once Chinese banking energetically strengthens the information system internal management, it can deeply improve the operation efficiency of informationization. The design and analysis of information system internal management is the fundamental prerequisite of Chinese banking information system internal management.

2 Design of Banking Information System Internal Management

Banking information system internal management is a highly technical and complex issue. Along with the extensive use of computer in the financial industry, commercial banks internal control has undergone tremendous changes. Manual operation has turned into the combination of manual control and computer control, or full automatic manipulation all by computer. Chinese commercial banks information system internal management can be generally divided into three aspects of system control, application technical control and inspection & supervision control. System control is the key of computer risk control. It has been proved to be a very effective method to regulate and restrain the behavior of people on the basis of the system and control mechanism. System control includes the organization control, management control, system development control, operation control, equipment control, documents & data control and some other aspects. The goal of application technical control is to ensure the timeliness, accuracy and completeness of data processing, and to prevent all ultra vires through technical and administrative means. The major technical control methods are password control, access control and background monitoring. Monitoring computer risk is a scientific and effective risk control, restrain and supervision system in order to effectively achieve the business objectives, maintain asset security and ensure timely and accurate accounting information. Major contents of inspection & supervision control on information systems are audit and examination to system development process, monitoring the implementation during the computer application and inspection of special circumstances^[5].

This study closely connects with the basic requirements of Chinese information system internal management. It designs information system internal management measurement system on PDCA principles. PDCA is a cutting-edge management concept, which is a cyclic process of plan (Plan), do (Do), check (Check) and (Act). Plan means establishing necessary objects and processes according to the business requirements and organizational policies. Do means acting the plan. Check means testing and evaluating the internal control according to the objects and policies. Act means taking measurements to improve the business performance continuously.

Chinese banking information system internal management is divided into four elements: the internal control design, the implementation of internal control, internal control evaluation and internal control improvement. Internal control design refers to the detailed design of the internal control information system, which provides goals and direction for the implementation of the system. The implementation of internal control refers to strict implementation of designed information system internal management in order to give full play to the internal control system functions. Internal control evaluation refers to evaluating the efficiency and effectiveness of information system internal management implementation, to determine the effectiveness of internal control system. Internal control refers to improving the internal control system according to the evaluation results, so as to achieve the upgrading and improvement of the internal control system.

Table 1 Information System Internal Management System

Ingredient	Index	Index definition
Internal management design	General control X1	Control the whole life cycle of the banking information system
	Systematic control X2	Control banking entire information system
	Risk-based control X3	Internal management design is good to enhance the risk management efficiency
	Technology-based control X4	Internal management design is able to make full use of the function of information technology
Internal management execution	Mode of internal management execution X5	Banks can select the executive methods scientifically
	Supervision of internal management execution X6	The internal actions of the information system can be supervised reasonably
	Encouragement of internal management execution X7	There is a effective encouragement inside the information system
	Efficiency of internal management execution X8	Internal management execution significantly reduces operation risks
Internal management evaluation	Strategic adaptability evaluation X9	The implementation of information system internal management coincides with the banks' strategic object
	Environmental adaptability evaluation X10	The implementation of information system internal management coincides with the change of the banks' environment
	Duty clearnessX11	The duties of department and administration inside the information system are divided clearly
	Internal management timeliness X12	The loopholes of information system can be solved immediately by the relation department
Internal management improvement	Technological improvement X13	Optimize internal information system continually along with the promotion of information technology
	Environmental improvement X14	Optimize internal information system continually along with the promotion of environment
	Customer requirement improvement X15	Optimize internal information system continually along with the change of customer requirement
	Information feedback improvement X16	Optimize internal information system continually along with the information feedback

3 Model Validation

This study has divided Chinese banking information system internal management into a structural model with 4-element and 16-indicator. Therefore, it can make use of confirmatory factor analysis to verify the model convergence and to verify the significance of factor loadings, factor correlation coefficient and indicators variance, and the overall fit of the model. So the structural model can be tested reasonably and realistically.

Table 2 Factor Loading Parameter List

Factor	X1	X2	X3	X4	X5	X6	X7	X8
Factor loading	.36	.43	.38	.11	.41	.28	.14	.22
SE	.09	.10	.11	.08	.08	.09	.10	.07
T	4.0	4.3	3.7	1.4	5.1	3.1	1.4	3.1
Factor	X9	X10	X11	X12	X13	X14	X15	X16
Factor loading	.33	.26	.19	.34	.44	.33	.30	.31
SE	.07	.09	.13	.09	.11	.11	.08	.08
t	4.7	2.9	1.6	3.7	4.0	3.0	3.8	3.8

This study made use of 7-point Likert Scales on the 16 indexes for data collection. The sample units were from city branches of the state-owned joint-stock banks, provincial branches of joint-stock commercial banks and city banks. 100 questionnaires were sent out and 90 available questionnaires were returned. The recovery rate was 90% which met the requirement that survey response rate should be higher than 20%. In the returned questionnaires, the study selected 84 high quality samples and the ratio of the sample number to index was 7:1, which can meet the requirement of the exploratory factor

analysis and confirmatory factor analysis. Among these, 15 samples were from Industrial and Commercial Bank of China. 14 were from China Construction Bank. 10 were from Agricultural Bank of China. 12 were from Bank of China. 13 were from joint-stock commercial banks. 20 were from city banks. Therefore, these databases can represent the general character of Chinese banking system. The respondents were executive officers in the banking information technology sectors or internal control departments. Therefore, the results had high credibility. The investigation dated from April 29th, 2013, to May 28th, lasted 30 days.

Making use of confirmatory factor analysis, this study obtained factor loading parameter list which was shown in Table 2 through SPSS11.5 and LISREL8.7.

The covariance matrix was showed in Table 3.

Table 3 Covariance Matrix

	Internal management design	Internal management execution	Internal management evaluation	Internal management improvement
Internal management design	1.0			
Internal management execution	0.25	1.0		
Internal management evaluation	0.19	0.26	1.0	
Internal management improvement	0.29	0.21	0.26	1.0

Then the fit index was showed in Table 4.

Table 4 Fit Index

<i>Df</i>	<i>CHI-Square</i>	<i>RMSEA</i>	<i>NNFI</i>	<i>CFI</i>
36	57	0.065	0.982	0.914

4 Conclusion

Results of the fit index show that the fitting effects of the model are good. Therefore, it is reasonable of the model which is designed for the study. The model can effectively reflect micro mechanism of the banking information system internal management.

According to Table 2, most factor loading values are relatively high, and are significant. Therefore, in the implementation process of Chinese banking information system internal management, the subject of internal control functions have been effectively implemented and achieved significant results. Meanwhile, the factor loading values of index X4, X7 and X11 are low and lack of significance. Therefore, there are still some weak links in banking information system internal management for improvement and perfection. First, the information technology should be given full play in the process of information internal control system, so as to gradually increase the intensity of the information internal control. This is the highest state of information system internal management. Second, Chinese banking industry should further strengthen incentives for the implementation of internal control to ensure that internal control strategies can be effectively implemented. There existed a wealth of incentive experiences of information of the internal control system in developed countries commercial banks, which can be references for Chinese banking industry. Finally, in the process of information system internal management, the role clarity needs to be further strengthened, and each position and responsibilities of bank information systems functions should be clear to enhance the binding strength of the job functions.

Known from the factor covariance matrix, the correlation between the internal control elements is generally low in information systems, which explains lacking of effective support between elements, functional elements presenting isolated state. The ingredients have not formed effective performance mechanism. Thus, Chinese banking information system internal management has achieved initial progress, but many functions need further development and improvement. Test results of this study can provide realistic theoretical references for deep implementation for information system internal management.

Abstract: Packet Pair (PP) algorithm is the primary method for measurement of network bandwidth bottleneck. Due to the limitations of clock granularity, the traditional PP algorithm has connatural measure error; and the precision of measurement can not be guaranteed when the clock resolving is larger than the interval between detecting packets. This paper proposes a PP algorithm for adaptive network bandwidth environment. The algorithm can adjust the size of detecting packets dynamically according to practical bandwidth, and reduce the impact of clock resolution on the measurement accuracy. The experimental results show that Adaptive Packet Pair (APP) algorithm can achieve higher veracity and stability than traditional PP algorithm.

Key words: Bandwidth measurement; Packet pair algorithm; Clock resolution; Adaptive bandwidth

1 Introduction

Network bandwidth is an important resource of the network. It is very important to estimate the network bandwidth accurately for optimizing the network configuration, enhancing network performance, improving service quality. However, owing to the size, structure, load changing and other factors of the Internet network, it is not easy to measure the network bandwidth accurately. People need to practice their own algorithms to adapt to different network environments^[1-2]. For example, the number of hops from source end to destination end, link multi-channel, background traffic and congestion, the end system clock resolution and synchronization etc. have increased the complexity of the algorithm; people need to make their own algorithm's load to the network as small as possible in order to avoid the impact of communications volume to the application data communication caused by the measurement^[3-4].

Bandwidth measurement method^[5-7] of the current study is mainly divided into two categories: one is Variable Packet Size (VPS) measurement method, a single packet-based measurement model, the typical algorithms Pathchar, Clink and Pchar; and the other is generally optimistic about the method, the package measurement method, based on Packet Pair (PP) measurement model, the typical algorithms are Bprobe, Nettimer, Pathrate and so on. A single package measurement model measurement tool is used to measure the link bandwidth of a path segment link, the link bandwidth is measured, and the minimum bandwidth value of that link bandwidth is the bottleneck bandwidth. Single package measuring method can also measure the bottleneck bandwidth of the path, but if you are only interested in bottleneck bandwidth, using this method is not worth the candle, not only the measurement speed is slow, the measurement accuracy is low, but it will also consume large amounts of network resources^[5]. The package measurement methods has changed this situation, it measure the network bottleneck bandwidth than a single package measuring algorithm has a clear advantage. However, in the actual bandwidth of the measurement process, the measurement system clock resolution often affects the estimation accuracy of the results^[8]. This paper proposes an Adaptive Packet Pair (APP) algorithm, which can effectively reduce the impact of clock resolution on the measurement accuracy and stability through dynamically adjusting the probes on the size.

2 The Measuring Principle of Package Pair Model

Packet pair (PP) model was first used in network congestion control, later it was improved and developed by R. Carte, V. Paxson and C. Dovrolis and others, the PP model become the most effective model of measuring network path bottleneck bandwidth^[9-10].

The PP transmission model was shown in Figure 1. Send a probe packet back from the source peer to back length, along path $P = \{a_0, a_1, a_2 \dots a_{i-1}, a_i, \dots, a_n\}$ to the same destination end, the probe packet length is S , the path followed nodes are $a_0, a_1, a_2 \dots a_{i-1}, a_i \dots a_n$, the link from a_{i-1} to a_i is L_i .

Figure 1 Packet Pair Transmission Model

If there is no other traffic on the link section, namely on the link two consecutive probe packets awaiting transmission, then the time interval after the two probes being transmitting on the link is:

$$\Delta T_i = S/B_i, \text{ Where } B_i \text{ is the link bandwidth of } L_i \quad (1)$$

Assuming the time interval through link L_{i-1} 's transmission is ΔT_{i-1} , and then the two probes time interval through transmission of link L_i is:

$$\Delta T_i = \max \{ \Delta T_{i-1}, S/B_i \} \quad (2)$$

Suppose the source sends the interval ΔT_0 is small enough, you can easily prove by induction that the time interval of the probe packet through the entire path is:

$$\Delta T_n = \max \{ \Delta T_0, S/B_{bn} \} = S/B_{bn}, \text{ Where } B_{bn} = \min \{ B_i, i=1, 2, \dots, n \} \quad (3)$$

So you can get the bottleneck bandwidth measuring expression based on the PP algorithms:

$$B_{bn} = S / \Delta T_n \quad (4)$$

This could measure the bottleneck bandwidth of the end to end path by sending back-to-back data packet pair with equal length.

3 The Impact of Clock Resolution

Clock resolution refers to the smallest unit of the clock change. The bandwidth estimation's (located at the destination) clock resolution is defined as R , assuming its true value of the package time interval is ΔT_n , the relation between estimating time interval $\Delta T_n'$ and ΔT_n as follows:

$$|\Delta T_n - \Delta T_n'| \leq R, \max(\Delta T_n - R, 0) \leq \Delta T_n' \leq \Delta T_n + R \quad (5)$$

The bandwidth estimation results got from $\Delta T_n'$ is:

$$B_{bn}' = S / \Delta T_n' \quad (6)$$

According to (5), (6), the bandwidth estimation error caused by R is:

$$B_{bn}' - B_{bn} = S / \Delta T_n' - S / \Delta T_n \quad (7)$$

The bandwidth estimation offset coefficient caused by the clock resolution R is defined as Ω ,

$$\Omega = (B_{bn}' - B_{bn}) / B_{bn} \quad (8)$$

$$\text{According to (7)、(8), } \Omega = \Delta T_n / \Delta T_n' - 1 \quad (9)$$

$$\text{According to (5)、(9), } \begin{cases} -\frac{R}{\Delta T_n + R} \leq \Omega & R \geq \Delta T_n \\ -\frac{R}{\Delta T_n + R} \leq \Omega \leq \frac{R}{\Delta T_n - R} & R < \Delta T_n \end{cases} \quad (10)$$

$$\text{So } \begin{cases} |\Omega| < \infty & R \geq \Delta T_n \\ |\Omega| \leq \frac{R}{\Delta T_n - R} & R < \Delta T_n \end{cases} \quad (11)$$

According to (11), when $R \geq \Delta T_n$, bandwidth measurement offset coefficient cannot be expected ; when $R < \Delta T_n$, the $|\Omega|$ within the range $[0, R/(\Delta T_n - R)]$, $R/(\Delta T_n - R)$ is the maximum deviation factor, denoted as Ω_{\max} .

For a given computer system, because R is constant, the maximum Offset coefficient bandwidth of different bandwidths' target path will be different^{[2][9][10]}. With the actual bandwidth of the target path B_{bn} increases, the maximum offset coefficient Ω_{\max} caused by clock resolution will increase. When B_{bn} increases to a certain extent, Ω_{\max} will rapidly increase, the algorithm estimation results have become unstable.

4 The Adaptive Packet Pair Algorithm for Measurement of Network Bandwidth

According to the above error analysis, in the PP algorithm, the offset coefficient Ω caused by bandwidth estimation's clock resolution only limited within a certain range in order to ensure the stability, effectiveness and accuracy of the algorithm.

According to (4) and (11), for the bandwidth estimation with a fixed clock resolution, offset coefficient Ω will depend on the actual bandwidth B_{bn} of the target path and the probe packet length S . In the case of large B_{bn} , properly increasing S can improve the accuracy of the measurement results, and the probe packets do not have a big disturbance to the path. To this end, we propose a packet measurement improved algorithm based on the bandwidth adaptive i.e. algorithm of packet pair (APP). For convenience, first define the reference bandwidth and the current maximum offset coefficient.

Reference Bandwidth: selected a bandwidth value as the basis for evaluation of the current offset coefficient by estimating the bandwidth historical data, saying that bandwidth as the reference bandwidth, expressed with B_{bn-ref} . The selection of the reference bandwidth influences the offset coefficient calculation, so the selected reference bandwidth should be able to better reflect the actual bandwidth B_{bn} .

Current maximum offset factor: according to the current probe packet length S , the reference bandwidth B_{bn-ref} and clock resolution R , the calculated maximum offset coefficient in (11) is called the current maximum offset coefficient, denoted as $\Omega_{max-cur}$, the offset coefficient caps denoted Ω_0 . Obviously, $\Omega_{max-cur} \leq \Omega_0$, according to (11) and the definition of $\Omega_{max-cur}$, there

$$R/(\Delta T_n - R) \leq \Omega_0 \tag{12}$$

$$\text{According to (4), } S \geq (1/\Omega_0 + 1) RB_{bn} \tag{13}$$

$$\text{Because } \Omega_0 \ll 1, \text{ so formula (14) is expressed as: } S \geq RB_{bn} / \Omega_0 \text{ approximately.} \tag{14}$$

In formula (14), for a determining measurement end system, clock resolution R is constant. Formula (14) shows that, for a given measurement result offset coefficient accuracy Ω_0 , the probe data packet length S of the measuring system should have a linear relationship with the capacity B_{bn} of network actual path, ie the length of the probe data packets to change adaptively with the path capacity's dynamically change, in order to improve the accuracy and stability of the measurement system. Therefore, the core of the bandwidth adaptive packet pair is dynamically adjusts the size of the probe packets S to satisfy formula (14).

5 The Algorithm Test

In order to investigate the influence of APP on improving clock resolution, this section will use the basic packet pair (PP) algorithm and bandwidth adaptive packet pair (APP) algorithm to estimate the two target paths' bandwidth. One is a bandwidth of 10Mbps; the other is a bandwidth of 100Mbps.

Firstly, we use the basic packet pair (PP) algorithm to estimate two paths bandwidth, and get two sequences. Using the policy based on the source end, the clock resolution of bandwidth estimation $R=1ns$, defining $\Omega_0=1\%$. In procedure, the measured data packet length is 500B (ie .4000b).

Through the previous formula $\Omega_{max} = R/(\Delta T_n - R)$, and $\Delta T_n = S/B_{bn}$, for the 10M links, $\Omega_{max} = 0.25\%$ is calculated, the result $\Omega_{max} < \Omega_0$ indicates that the offset coefficient estimated meets the requirement; for 100M link, we calculate $\Omega_{max} = 2.56\%$, the result $\Omega_{max} > \Omega_0$ indicates that the offset coefficient is too large, the result is not stable and accurate .

Table 1 The Obtained Bandwidth Estimation Sequence Table of PP Algorithm

Path type	Min(bps)	Mean(bps)	Max(bps)	Stddev(bps)
10M	7,732,165	9,055,060	9,876,543	304,835
100M	4,798,212	76,042,418	98,291,535	13,850,576

Table 2 The Comparison Table of two Algorithms' Bandwidth Estimation Sequence

Path algorithm	Min(bps)	Mean(bps)	Max(bps)	Stddev(bps)
100M PP	4,798,212	76,042,418	98,291,535	13,850,576
100M APP	38,1201,246	81,017,266	94,605,831	10,072,062

Table 1 shows the statistical results of two estimation sequence, the sequence length is 1000 (1000 times each test). the estimation sequence's accuracy of 10M Link can reach an average of 90.55%,the standard deviation of the sequence is 304,835bps,poor deviation is 2.144Mbps,which indicate the

sequence very stable; the estimation sequence's accuracy of 100M Link can only reach an average of 76.04% ,the standard deviation of the sequence is 1.385 bps, poor deviation is 93.50Mbps.

Then we use adaptive packet pair (APP) algorithm to optimize the 100M link bandwidth estimation. The policy based on the source end is still used, and selecting the average estimate bandwidth as reference bandwidth. According to formula (14), defining the adjustment formula of the measurement data packet's length:

$$S_0 = \frac{RB_{bn-ref}}{\Omega_0} \quad (15)$$

Adjusting S to an integer multiple of $(100 * 8) b$, the final adjustment formula S is:

$$S = \left[\left(\frac{1}{\Omega_0} RB_{bn-ref} + s' \right) / 800 \right] * 800 \quad (16)$$

S' is the packet length to obtain a certain degree of measurement accuracy margin additional, $[]$ indicates integer.

For the tested link 100 M, if the clock resolution $R=1ns$, requires $\Omega_0 \leq 1\%$, according to the formula (15) $S_0=10000b$, $s'=400b$, by the formula (16), in this case S is adjusted to 1300B, ie 10400b.

The Statistical results of Table 2 shows the optimized estimation sequence's average accuracy rose to 81.02%, while the standard deviation of the sequence reduced to 10.072Mbps, poor deviation reduced to 56.50Mbps. Through test comparison it can be seen that APP algorithm has more accuracy and more stability.

6 Conclusions

This paper analyzes the principle of the packet pair (PP) measurement model, and proposes a bandwidth adaptive packet pair (APP) measurement algorithm with improved measurement performance against the influence of clock resolution on measurement results. Based on the basic packet pair measurement algorithm, the algorithm meets the bandwidth measurement accuracy requirements according to the size of the tested path's bandwidth capacity dynamic adjustment probe packets. Bandwidth adaptive packet pair (APP) algorithm has more accuracy and more stability than the basic packet pair (PP) algorithm, but further exploration in reducing the impact of background traffic is still needed.

Abstract: Regarding the air routing problems of logistics express delivery industry, we considered increasing cost so as to completely meet the delivery time requirement, a programming model of air routing problems with hard time window, which was solved by parallel genetic algorithm, was presented. Meanwhile, the soft time window model was constructed to compare with the result of the hard window's, by building and applying satisfaction function. Numerical contrast analysis showed that the hard time window is of high cost as well as a greater satisfaction degree. This planning is more suitable for the character and requirement of the mid-market logistics.

Key words: Hard time window; Soft time window; Vehicle routing problem; Desirability function, Mid-market logistics; Parallel genetic algorithm

1 Introduction

Vehicle Routing Problem (VRP) is widely used in the area of transportation, logistics distribution, etc., to solve the combinatorial optimization problem. This kind of problem can be described as follow: a vehicle departures from one or more sites, visits the customer and completes the corresponding handling requirement. The goal is to get the feasible distribution path to minimize the total cost, which is also called the optimal objective function, by satisfying certain constraints. The optimal objective is always measured by the least number of vehicles, the total distribution distance and time. Vehicle Routing Problem with Time Window (VRPTW) is extended from the traditional VRP by adding a Time Window, which can be divided into hard Time Window (HTW) and soft Time Window (STW). Fabri and Recht^[1], David^[2] has made some detailed summary to the VRP, VRPTW and its deformation. Zhang Jian^[3] has studied the STW model, which can reach the minimal cost by taking more time. Ali^[4] has constructed a semi-soft time window, just constraining delivery time. Tas et al.^[5] has studied VRP with stochastic travel times including soft time windows and service costs. Tao & Liu^[6] has studied the STW, which has various kind of vehicles and expense. Chang-Ing^[7] has solved the optimal routing problem with multi-objective constrains, breaking through the limitation of judging solely on a cost. Vladimir^[8] and Miguel^[9] has given a narrative of the method to get the optimal routing of STW. However, it can be figured out that in area of VRPTW, most of the studies has concentrated on the STW, thus leading a lack of the research of HTW, multi-model problem and the advantage comparison between the soft and hard time window. Work on these topic include, Tsung-Sheng^[10] constructing a problem of stochastic dynamic of HTW. Li Jian^[11] has studied the HTW planning model with multi-vehicles, but his study is based on the rental car and didn't concern the fixed costs, while most of the air express using their own cargo airplanes. To address this situation, this paper make a goal of the minimal cost, to locate in midmarket, fully guarantee the effectiveness and constructive a VRPHTW model. Using the parallel genetic algorithm, we got the optimal routing. In the end, we considered the soft time window with the minimal cost and construct a satisfaction function to analysis.

2 Description of VRPTW Value-Added Chain and Mathematical Model

2.1 Problem description

Consider a route planning model consist of one logistic transfer station and N target cities. Suppose the i th customer has m_i transport volume and $m_i < Q_k$ (Q_k is the capacity of k th cargo aircraft), the logistic transfer station sent several cargo aircrafts to deliver goods to N customers. The plane must arrive within a certain time range $[e_i, l_i]$, that is to say, not earlier than e_i and not later than l_i . literature^[7] shows the transportation costs includes the leasing costs and the fuel cost related to transportation distance. Assume the logistic company we studied using its own cargo airplanes, so we didn't calculate the leasing cost but took the fixed cost of purchasing cargo. Except meeting the

arrival time requirements, this model also considered the aircraft capacity, constrains of various types of aircrafts and site constrains, and so on. This model aims to solve out the air line of least cost and full satisfaction of demand.

2.2 Basic assumptions

- (1)The flight of every cargo starts and ends at the same logistic station;
- (2)Every target city can only be served once by one cargo;
- (3)total demand of each route should not exceed the corresponding cargo aircraft’s capacity Q_k ;
- (4)Each air line will content a certain time window constrains;

2.3 Notations

- $G = (N, A)$ denotes an undirected complete graph;
 - 0 denotes the logistic transfer station;
 - $\{1, \dots, n\}$ denotes a cities set;
 - $K\{1, 2, \dots, m\}$ denotes a cargoes set;
 - d_{ij} denotes the Euclidean distance between city i and city j ;
 - t_{ij} denotes the flight time from city i to city j ;
 - c_{vk} denotes the travel costs per hour of the kth kind of cargo;
 - c_{kf} denotes the fixed cost of the kth cargo;
 - c_{ijk} denotes the transportation cost of kth cargo from city i to city j , $c_{ij} = c_v d_{ij}$;
 - m_i denotes the goods demand of city i ;
 - Q_k denotes the capacity of kth airplane;
 - l_0 denotes the lasted time the cargo back to the departure airport;
 - t_i denotes the time reaching at city i ;
 - l_i denotes the time when city i can accept the goods;
 - s_i denotes the integrated and discharge time in city i , $s_0 = 0$;
 - w_i denotes the waiting time in city i ;
 - q_{ijk} denotes cargo capacity of the kth cargo from city i to city j .
- $$y_k = \begin{cases} 1 & \text{choose the } kth \text{ cargo} \\ 0 & \text{not choose the } kth \text{ cargo} \end{cases} \text{ and } \sum y_i = 1$$
- $$x_{ijk} = \begin{cases} 1 & \text{(cargo } k \text{ fly from city } i \text{ to city } j) \\ 0 & \text{(cargo } k \text{ don't fly from city } i \text{ to city } j) \end{cases}$$

2.4 Model construction

Mathematical model:

$$C_h \min Z = \sum_{i=1}^n \sum_{k=1}^m C_f x_{i0k} + \sum_{i=0}^n \sum_{j=0}^n \sum_{k=1}^m C_{ij} y_{ijk}$$

$$\text{For } i = 0, \sum_{k=1}^K \sum_{j=1}^N x_{ijk} = K \tag{1}$$

$$\sum_{j=0, j \neq i}^n q_{ijk} - \sum_{j=0, j \neq i}^n q_{jik} = m_i, i \in N, k \in K \tag{2}$$

$$\sum_{j=1}^n x_{0jk} = 1; k \in K \tag{3}$$

$$\sum_{i=0, i \neq h}^n x_{ihk} - \sum_{j=0, j \neq h}^n x_{hjk} = 0, \quad h \in N, \quad k \in K \quad (4)$$

$$\sum_{i=1}^n x_{i0k} = 1; \quad k \in K \quad (5)$$

$$\sum_{j=1, j \neq i}^n \sum_{i=1}^n q_{ijk} y_k \leq (Q_k - m_i) x_{ijk}; \quad i \neq j, i, j \in N, k \in K. \quad (6)$$

$$\sum_{j \neq i, j=1}^n \sum_{i=1}^n q_{ijk} y_k \geq m_i x_{ijk}; \quad i \neq j, i, j \in N, k \in K. \quad (7)$$

$$t_{ij} = d_{ij}, \quad \forall i, j \in \{0, 1, \dots, N\}, \quad i \neq j \quad (8)$$

$$t_j = \sum_{k=1}^K \sum_{i=0, i \neq j}^N x_{ijk} (t_i + w_i + s_i + t_{ij}), \quad \forall j \in \{1, 2, \dots, N\} \quad (9)$$

$$e_i \leq t_i \leq l_i \quad (10)$$

$$D_k = \sum_{i=0}^n \sum_{j=0, j \neq i}^n x_{ijk} d_{ij}; \quad k \in K \quad (11)$$

$$\eta = \frac{\sum_{i=1}^n \sum_{j=1}^n m_i x_{ijk}}{\sum_{i=1}^n \sum_{j=1}^n q_i x_{ijk}} \quad (12)$$

The objective function mainly consisted of the fixed cost of cargo aircrafts and variable costs. The fixed cost related to the number of vehicle used. The variable cost related to the expense when completing a transport, concerns the vehicle distance and traffic on every sections .formula (1) is number constrains: the transit city i has only K cargos, all should be used. Formula (3)(4)(5)is the station constrains: each cargo should departure from the central city, provide distribution services to other cities and then come back to central city. Formula (6)(7) is the capacity constrains: in the line between city i and city j , the capacity of cargo k , which at least should meet the requirement of the served city j , is no more than its capacity constraints .Formula (9) means the time-consuming flying from city i to city j is represented by Euclidean distance between the two cities. Formula (9) express the time t_j when reaching the city j equals to the sum of the time when departing the previous customer, which consisted of the arrival time and waiting ,unloading and integration time in this city, and the flight time between the two cities. Formula (10) is time constrains: all of the cities should be served and the first city can't be served before the earliest time provided and the last city should be served before the latest time provided. Formula (11) is the total route distance which must be returned when calculating. Formula (12) means the cargo aircraft utilization.

2.5 Model solution

Here the parallel genetic algorithm^[9] is used to solve the problem. After running parallel several generations, several individuals with high adaption will be selected out from the two stocks to tip the balance. This can overcome the disadvantage of the traditional genetic algorithm, which has a limitation in its function to break internal balance between different stocks, and promote all the stocks to evolutes towards a higher equilibrium to get the best individual.

Step 1: $gen = 0$, use natural number encoding and random initialization to generate stock A . Use construction method to generate stock B and input control parameters (crossover probability P_c , Mutation probability P_m scale of stocks A and B : POP_A, POP_B .largest number of running generations $Maxgen$ and complex parameter α);

Step 2: Calculate the fitness of stocks A and B ;

Step 3: If $gen \leq 10$ or $gen \leq Maxgen$, $gen \% 5 \neq 0$ (denotes the genetic variation generations is not a multiple of 5), go Step 4; if $gen \leq Maxgen$, $gen \% 5 = 0$ go Step 5; or stop calculation and output the optimal solution;

Step 4: Stocks A and B do genetic operation solely (fitness calculation, select, cross, variation);

Step 5: Select out the optimal individual (the solution) from stocks A and B , then put them respectively into stocks B and A , go step 4;

Step 6: $gen = gen + 1$.

3 Numerical Example

3.1 the programming result of the hard time window

Using the given data, it can be figured out if making the routing planning to all the cities simply, when considering the two cities has significant difference between the freight, the utilization of the cargo will be uneven. So it is necessary to set the cities with a big traffic, like Beijing, Wuhan, as the transfer station of a relative area, the goods of which will be assembled in its corresponding transfer station and go to other cities. Through literature^[5] we know the delivery to and from cycle is 16 hours. Take Beijing as an example, corresponding data are listed in Table 1 and Table 2:

Utilize the parallel genetics algorithm to solve the problem, Setting the parameters as: the scale of stock A is 50, so stock B is mainly used to break the stocks balance of A , so the scale of stock B is 20. Every 5 generations the two stocks will exchange its optimal chromosome with a number of 3. the running generation is 5000, cross and variation probability is 0.75 and 0.01. Utilize MATLAB to simulate 20 times and get the optimal solution 12 times with the minimal distribution cost of 64176 Yuan. The optimal total routing length is 64.5875 thousand kilometers, the planning result is showed in Table 3, the route graph is shown in Figure 1.

Table 1 Coordinate, Demand and Time Window of Beijing and Other Cities

	1	2	3	4	5	6	7
q_i	0	-1	0	4	5	5	4
s_i	0	6	11	4.5	5	7	9.5
$[e_i, l_i]$	[0,16]	[2,6]	[6,10]	[2,8]	[2,8]	[2,8]	[6,10]
X	28756	10297	10000	10000	10000	10000	10000
Y	32875	10000	10000	10000	10000	10000	10000

(Note: 1-Beijing, 2-Wuhan, 3-Shengzhen, 4-Wuxi, 5-Shanghai, 6-Hangzhou, 7-Quanzhou)

Table 2 Cargo Running Cost

types	Cost per hour			Pay-load(ton)
	4 hours per day	6 hours per day	8 hours per day	
B737	4.5	4	3.5	14
B757	7.5	7	6.5	28
A300	8.5	8	7.5	40

Table 3 Programming Result of Hard Time Window

Flight NO.	route	type	Cargo utilization	Running cost
1	1-3-7-1	A300	82.68%	24893
2	1-2-6-1	B737	69.86%	20051
3	1-5-4-1	B757	71.78%	19232

Figure 1 The Programming Routing Graph of Hard Time Window

3.2 Result comparison with the hard time window

Change the problem into the STW, with reaching a less cost while taking more time. Make change to the target function: add time penalty, then the target function change into:

$$\min Z = \sum_{i=1}^n \sum_{k=1}^m C_f x_{i0k} + \sum_{i=0}^n \sum_{j=0}^n \sum_{k=1}^m C_{ij} y_{ijk} + \sum_{i=0}^n \sum_{k=1}^m PT_{ik}$$

Change formula (4) and (5) into $T_{jk} = T_{ik} + T_{ijk} + s_{ij}$ $i, j \in N, k \in K$, while T_{ik} is the time when cargo k arrive at city i , T_{0k} is the departure time, T_{ijk} is the flight time of cargo k from city i to city j . Add constrains:

$$PT_{ik} = \max\{p^e (e^i - T_{ik}), 0, p^l (T_{ik} - l_i)\} \tag{13}$$

Formula (13) is the time penalty value because cargo k arrive at the city early or late, p_e, p_l is the penalty coefficient, which value are taken as possible. generally believed that arriving early is better than arriving late, so the early penalty is smaller than late penalty, that is to say, $p_e < p_l$.

Take Beijing as an example, the planning result is showed in Table 4:

Table 4 Programming Result of the Soft Time Window

Flight NO.	route	Running cost	The excess time or early time	Cargo utilization
1	1-5-4-1	20684	92min	88.68%
2	1-6-7-1	19762	43min	72.36%
3	1-2-3-1	22758	123min	75.28%

The total running cost of VRPSTW planning route is 63204 Yuan.

Since this paper aims to the mid-market logistic company, so the standard to measure the route should not be limited in the cost, the customer satisfaction caused by the timeliness is a more important aspect. Thus, the satisfaction function, which is constructed to both take the timeliness satisfying customers and cost satisfying the company into consideration, is estimated as: $F = \alpha\Gamma + (1 - \alpha)\Psi$.

While F is the satisfaction function, which is on the basis for a company's long-run strategy; Γ is the time measurement function, its formula is:

$$\Gamma = 1 - \frac{\max\{(e^i - T_{ik}), 0, (T_{ik} - l_i)\}}{\sum_{i=1}^n \sum_{k=1}^K \{(e^i - T_{ik}), 0, (T_{ik} - l_i)\}}$$

Obviously, to hard time window, $\Gamma = 1$; Ψ is the cost measurement function, with a formula as:

$\Psi_{s(h)} = 1 - \frac{C_{s(h)}}{C_s + C_h}$, while C_s is the total cost of STW planning. C_h is the HTW's.

Since this paper just discuss the mid-class logistic company, its market positioning determined the customer maintain a high requirement to the timeliness and incentive to the price. Thus we take $\alpha = 0.7$. The calculation result can be found in Table 5:

Table 5 Comparison of the Satisfaction

	Hard time window	Soft time window
F	0.756	0.548

We can infer that: though the soft time window planning model can reduce the cost of logistic companies, however, in terms of mid-market logistic company, using the hard time window to plan the route can guarantee the goods being sent on time, thus the better satisfaction can be got.

4 Conclusion

This paper studied the problem of air route planning, constructed a optimization model of the HTW under the strict assurance of timeliness, to plan the route between the setting logistic transfer station. The overall satisfaction degree function, which aims to the mid-market logistic company, has been constructed to compare the HTW and STW. The result shows the HTW will get a larger satisfaction function than the soft one. However, this study was limited to the self-purchasing cargo and didn't take the 'bulk air' into consideration. If we take this into consideration, then the departure time of the goods is not a fixed cycle and the question will become more complex. The further discussion will be done in the future research.

Research on the Principle of the Risk Conduction Intensity in the Enterprise Financial System

Deng Mingran, Wang Hui, Ma Ying
 School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070
 (Email: 1468585137@qq.com, mying3312163.com)

Abstract: This paper describes the principle of the risk conduction intensity in the enterprise financial management system, which includes Weak coupling (the recession risk conduction principle), pure coupling (the stable risk conduction principle), and Strong coupling (the growing risk conduction principle). And this paper reveals connotation and characteristics of these three principles, and has a guiding significance for enterprises that use the modern financial management theories and methods to predict and control risks of enterprise financial management system and its conduction in the dimension of strength.

Key words: Risks conduction; Enterprise financial management system; Weak coupling; Pure coupling; Strong coupling

1 Introduction

Risks, in the enterprise financial management system, start from the source of risk and conduct between link nodes via Conduction carrier and Conduction path. Since each link node has its certain external environment and internal environment factors to influence financial risk source, the risk of export of Enterprise financial management system will change its strength, after the risk of external import and the risk at this link node meet. And we call this change the risk intensity of Enterprise financial management system. From the view of Mutual coupling of risk flows, it can be divided into Weak coupling, pure coupling and Strong coupling .and from the view of the influences made by the risk flows; it can be divided into the recession type of Risk, the stable type of Risk and the growing type of Risk. And this Two kinds of classifications have some Internal relations, which shown as follows Figure 1.

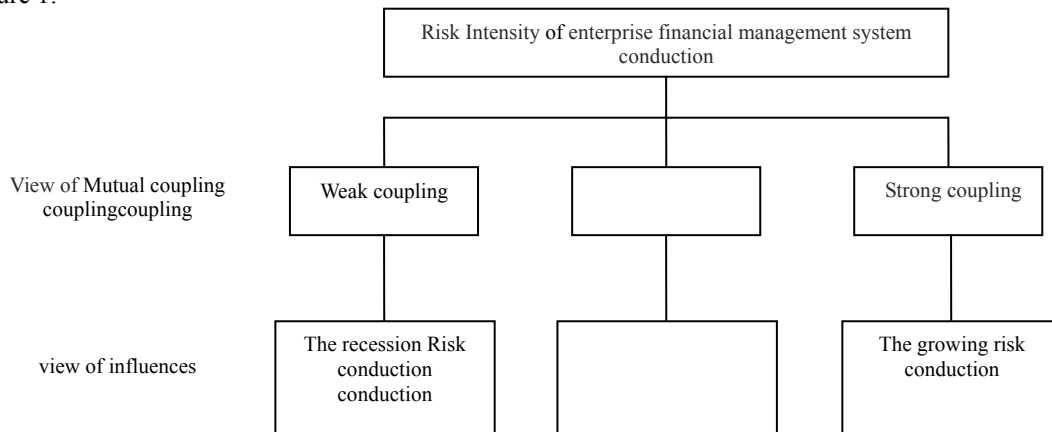

Figure 1 The Intensity of Enterprise Financial System Risk Conduction

2 Weak Coupling – the Recession Risk Conduction Principle

In the process of enterprise financial management system risk conduction, if two different risk flow—the link node A and B coupled during delivery process, and the total flow of risk becomes smaller after coupling ,In other words, the total flow subsides by the process of coupling, and achieve “1 + 1 < 2”. And this kind of coupling is “weak coupling”.

The formation of “weak coupling” of Enterprise financial management system risk flow is due to that two kinds of risk flows show a negative correlation and coupling degree between them is low, and The internal and external environmental factors of link node A and those of link node B block weaken each other in the process of risk conduction, making the overall risk flows decrease. In other words, in a certain period of time, with the time going on, corporate financial risk flow weakened gradually in

the process of conduction. This feature is called a recession risk conduction type, and it can also be called decrescendo type of risk conduction.

Recession type risk conduction has many kinds of patterns, such as linear, diminishing type, wave type, S type and so on, which is shown Figure 2.

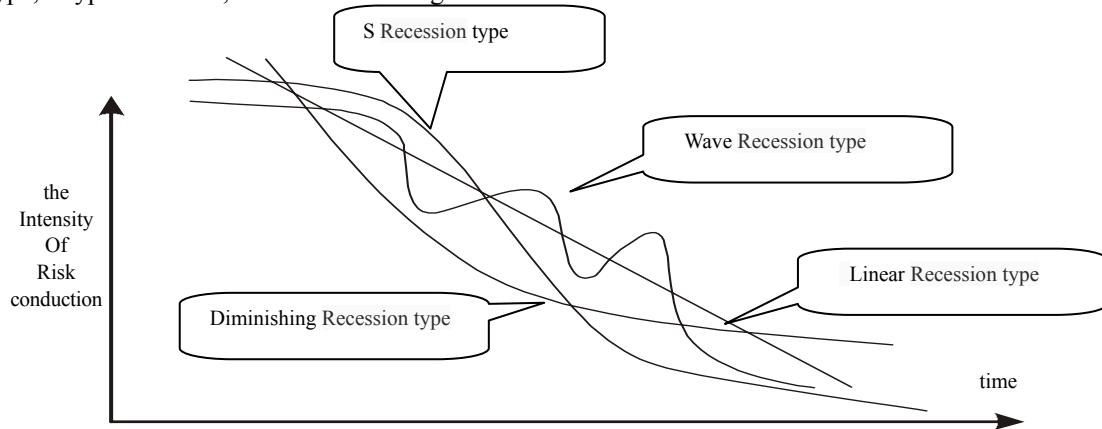

Figure 2 The Recession Risk Conduction Model

Recession risk conduction model, it is ferocious generally at the beginning, generally with a sudden, unpredictable and hard to guard against. And it is so harmful and has strong penetrating power at early period. But once its regularity is found out, strong measures can be taken to control it effectively. In 2008, for example, the outbreak of the subprime mortgage crisis in USA caused the economic volatility, led to business failures, unemployment of large number of workers, and panic and social unrest. And this spread to the world at the same time, some national economy was hit, almost to the brink of collapse, some countries Suffered from loss seriously. But with the passage of time, the national government attached great importance to the correct steps. For example the United States took out \$700 billion financial rescue, China took out 4 trillion yuan to stimulate domestic demand. All countries had strong measures to make the U.S. subprime the global financial crisis caused by mortgage crisis triggered eased. And the risk intensity was gradually weakened, and the world economic situation got better in the coming 4 to 5 years.

3 Pure Coupling – the Stable Risk Conduction Principle

In the process of enterprise financial management system risk conduction, if two different risk flow —the link node A and B coupled during delivery process, and the total flow of risk remains the same after coupling, In other words, the total flow doesn't change by the process of coupling, and achieve “1 + 1 =2”. And this kind of coupling is “pure coupling”.

Figure 3 The Stable Risk Conduction Model

The formation of the “pure coupling” is due to that the two kinds of enterprise financial management system risk flows are not associated and risk flow coupling degree is almost zero at this point, The internal and external environmental factors of link node A and those of link node B are independent in the process of risk conduction, making the overall risk flows remain the same. In A certain period of time, the total risk flow presents a uniform and stable characteristics in the process of financial management system risk flows conduction. This feature is called stable risk conduction, and this stability can be described that risk conduction system is around a constant value within a certain

range of fluctuation, which means that the enterprise financial risk conduction amount is relatively stable, not absolutely stable.

The stable risk conduction includes continuous stable conduction and intermittent stable conduction, which is shown in Figure 3.

Risk stable conduction model generally has the Characteristics of balance, stability, controllability and basic. This is because the stable conduction generally refers to conduction of the risk with a small fluctuation. Interest rate risk and exchange rate risk is exactly this kind of risk conduction. Changes in interest rates and exchange rates are not big and will stay for a long period of time. Its impact can be estimated and predicted, and risk degree is controllable.

For example, according to the national macro policy and economic environment conditions, countries announced a 0.2% increase of Bank loan interest rates. This means that the enterprise financing cost is also increased by 0.2%. And the policy plays a some certain degree of influence in other related enterprise financial activities. Bank loan interest rate changes with relative stability, not at random, and thus the impact on corporate profits is also relative stable.

4 Strong Coupling – the Growing Risk Conduction

In the process of enterprise financial management system risk conduction, if two different risk flow—the link node A and B coupled during delivery process, and the total flow of risk becomes larger after coupling, In other words, the total flow is strengthened by the process of coupling, and achieve “1 + 1 > 2”. And this kind of coupling is “strong coupling”.

The formation of "strong coupling" of Enterprise financial management system risk flow is due to that two kinds of risk flows show a positive correlation and coupling degree between them is high. And the internal and external environmental factors of link node A and those of link node B block strengthen and contribute each other in the process of risk conduction, making the overall risk flows increase.

In other words, in a certain period of time, with the time going on, corporate financial risk flow is strengthened gradually in the process of conduction. This feature is called growing risk conduction or the mounting risk conduction. Enhanced risk conduction have many kinds of patterns, such as linear enhancement, one by one add type, wave type of enhancement, S enhancement and so on, which is shown in figure 4.

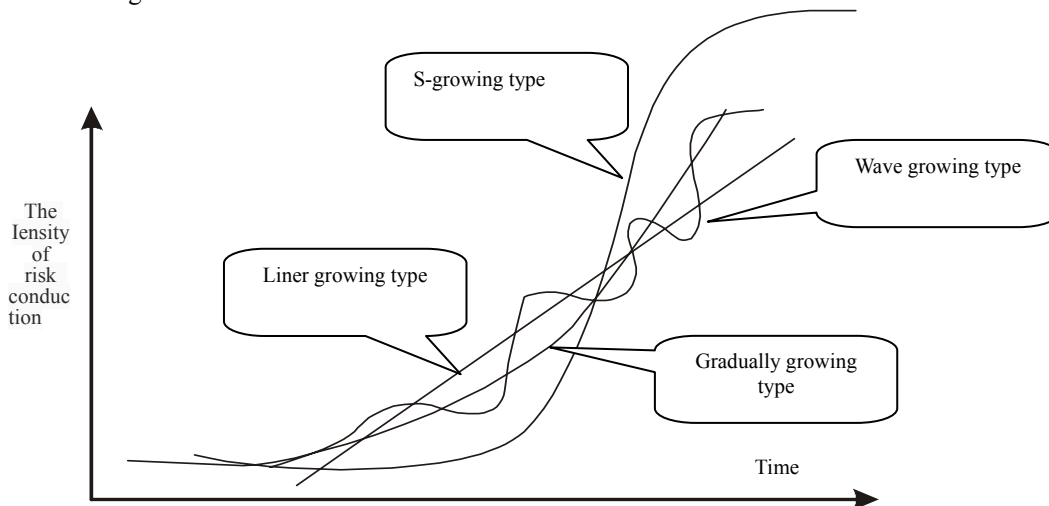

Figure 4 The Growing Risk Conduction Model

Enhanced risk conduction model, it doesn't even have the hazards in the early period of time. Then it develops very quickly at the middle time. And the later the period is, the more harmful and destructive the risk will be. And it has the characteristics of directionality, unbalance and gradually strong.

For example, the mid and late 1980s, in order to improve people's living standards, all walks of business generally increased wages by level 1 or level 2 or level. But it failed to improve labor productivity, which meant that the unit product cost was rising. To guarantee the profits, enterprises raised prices of their products. From the point of value chain, if the prices of every tons of iron is rising, metallurgical raw materials cost will rise, along with rising wages in the industry. If they fail to improve

productivity or not improve enough to reduce raw material costs and rising wage costs, to guarantee their profit, they will have to raise the price of per ton steel. Similarly, many manufacturing companies which use steel as raw materials will have to raise product prices. Finally, it will lead to the rise of prices of personal products, resulting in a decline in living standards. In order to solve this problem, pay rises will be raised. And if labor productivity cannot be improved greatly, it will form a vicious circle—people's living standards decline, causing the people's discontent and social instability. This kind of risk conduction passes along the value chain, and it is a kind of enhanced risk conduction.

5 Conclusions

(1)Enterprise financing system risk conduction intensity principle includes weak coupling type - recession risk conduction principle, the pure coupling - stable risk conduction principle and the strong coupling - growing risk conduction principle;

(2)The weak coupling—recession risk conduction principle means that corporate financial total risk flow becomes smaller and reach “ $1+1<2$ ”. It has the characteristic that, with the time going on, it is weakened gradually in the process of conduction.

(3)The pure coupling—the stable risk conduction principle means that corporate financial total risk flow keeps relatively stable and reaches “ $1+1=2$ ”. It has the characteristic that, with the time going on, it is relatively stable in the process of conduction.

(4)The strong coupling—growing risk conduction principle means that corporate financial total risk flow becomes bigger and reach “ $1+1>2$ ”. It has the characteristic that, with the time going on, it is strengthened gradually in the process of conduction.

The analysis and acquisition of the enterprise financial risk conduction system intensity principle is helpful for the enterprises in that they can use of modern financial management theory and methods to predict risks and control the risks in enterprise financial management system from the dimension of the intensity of enterprise financial management system risk conduction, so that they can realize the enterprise financial goals and improve economic efficiency of enterprises.

Logistics Engineering Curriculum Based on Experiential Learning Environment: An Example*

Liu Zhe

School of Management, Henan University of Technology, Zhengzhou, P.R. China, 450001

(E-mail: liuzhe168@163.com)

Abstract: This study aims at emphasizing the pedagogical methodology of Logistics Engineering, which is a branch of systems engineering dedicated to the scientific organization of the purchase, transport, storage, distribution, and warehousing of materials and finished goods. In today's environment, there is a critical need to improve acquisition program workforce training to reduce persistent problems in program outcomes related to technical performance, schedule and cost. Experiential learning is likely to be more effective if it gives students opportunities to practice what they are trying to learn applies not only to education for work. Software simulation, as a main element of instruction process, besides teaching and learning, must be conceived and realized as an effect of curricular approach of education and instruction. This way of thinking leads to a certain path in teaching methods, which will be highlighted in the Logistics Engineering curriculum.

Key words: Logistics Engineering; Experiential learning; Teaching methodology; Simulation

1 Introduction

The first rule of business is “know your customer”. However, most educational programs that teach functional area topics focus mainly on the technical knowledge for the particular function, not on cross-domain knowledge or on the knowledge needed to use multidisciplinary methods for knowledge elicitation and influence. This latter type of knowledge typically is gained by on-the-job experience and can take many years. In today's environment, there is a critical need to improve acquisition program workforce training to reduce persistent problems in program outcomes related to technical performance, schedule and cost.

Experiential learning models (e.g. Kolb, Rubin, & McIntyre, 1984) have been applied in academic settings to provide methods to better engrain key concepts in students. Kolb, Rubin, and McIntyre's model incorporates experience, reflection, and conceptualization to enhance learning. Similarly, action learning (Revans, 1980) and active learning (Lawson, 2006; Ross, 2011) focuses students' academic experience on learning by working on real organizational problems. Other models of learning (e.g. social learning theory and behavioral model training) have been used to improve student learning by other methods (Hess, 2007). In fact, there exists a significant debate and alternative theoretical views on the most effective process of learning (McEvoy, 1998); for example, Ramsey (2005) identifies three problematic assumptions within an experiential framework. Another learning process model, problem-based learning (Brownell & Jameson, 2004), has been advocated for helping students link theory to practice (Sherwood, 2004).

This paper is organized as follows. Section 2 reviews the objectives of Logistics Engineering from 6 aspects. Section 3 puts forward the view of education as preparation for active problem solving and participation in the world. Section 4 discusses the simulation model to be used in one chapter of this course. Finally, Section 5 concludes and provides avenues of future research.

2 Course Objectives

Logistics engineering is a branch of systems engineering dedicated to the scientific organization of the purchase, transport, storage, distribution, and warehousing of materials and finished goods. Logistics engineers work with complex mathematical models that consider elements such as mean time between failures (MTBF), mean time to failure (MTTF), mean time to repair (MTTR), failure mode and effects analysis (FMEA), statistical distributions, queuing theory, and a host of other considerations. Obviously, logistics engineering is a complex science that considers tradeoffs in component/system design, repair capability, training, spares inventory, demand history, storage and distribution points, transportation methods, etc., to ensure the “thing” is where it's needed, when it's needed, and operating the way it's

* This paper is supported by Logistics Center of Henan Humanities and Social Science Research Fund and Excellent Education Project of Henan University of Technology(No.YPGC2011-WO3)

needed all at an acceptable cost. Thus, students can understand these course objectives from 6 aspects, which are called 5W1H.

- Why (purpose & functions)

Study logistics from a systems engineering perspective. Covers design of systems for supportability and serviceability, the production and effective distribution of systems for customer use, and the sustaining maintenance and support of systems throughout their period of utilization.

- Where and When

Logistics provides an interesting application for these environments, as it is characterized by risk and disruptions, interactions with other parties (e.g., suppliers, transport providers, customers) and multiple performance metrics (e.g., cost, on-time delivery, penalties, profit). Thus, a number of efforts have addressed experiential learning for commercial logistics applications, with the intent to teach such concepts as inventory management, meeting customer expectations, cost analysis and minimization, and emergent supply chain phenomena such as the bullwhip effect. Those theories and methods of this course are always widely practiced in a lot of sectors, including manufacturing and service industries.

- Who (employment opportunities)

After graduation students may work, for example, as a planner, developer, manager, consultant, trainer, supervisor, or entrepreneur. Possible job titles include logistics engineer, development engineer, purchasing engineer, inventory manager, supply chain coordinator, warehouse manager, logistics manager, transport manager

- What(knowledge & skills)

Upon completion of this course, students will be able to:

- (1) Define logistics and the elements of an engineering logistics system
- (2) Apply engineering tools to logistics system design
- (3) Use quantitative tools to analyze and evaluate logistic system performance
- (4) Examine logistics decisions involved in life cycle design
- (5) Evaluate a life cycle cost for an engineering system
- (6) Apply trade off analysis to logistic system analysis
- (7) Evaluate and apply forecast models to logistic systems.

- How(learning methodology)

One avenue to improve training involves use of educational technology, in particular role-based experiential learning. This paper explores the creation of such a learning environment in which a learner assumes the role of a logistician who must not only understand issues in his or her functional area, but also must interact with systems engineers to understand the implications of decisions in that functional area on logistics. This environment is based on the software of FLEXSIM, an existing prototype learning environment used for logistics engineering workforce development.

3 Teaching Methodology

The reasons need to change teaching methods can be summarized as:

- The lecturer was dissatisfied with the traditional lecture teaching because of: 1) the low number of students that pass the subject every year, 2) the high rate of absenteeism, which is progressively higher during the semester and 3) the high number of drop-outs (students who do not attend the exam).

- To be positioned more in accordance with the European Higher Education guidelines that suggest moving learning systems to more student-centered teaching methods.

- Student acquisition of high quality learning outcomes wherein specific and general skills are developed should be a challenge for a lecturer in Higher Education. This is difficult with the traditional lecture approach.

The theory that education is likely to be more effective if it gives students opportunities to practice what they are trying to learn applies not only to education for work. Mathematics, for example, is best learned by students constructing their own proofs and demonstrations. The common sense of learning by doing has been upheld by philosophers and more recently by cognitive scientists. This argument is linked to a view of education as preparation for active problem solving and participation in the world. Although learning by doing has most often been a feature of vocational and professional education, it is now argued that all knowledge, including the sciences and humanities, is created, defined, and transmitted by communities of practice (Linn et al., 2004).

These types of environments often use Kolb's concept of experiential learning, which consists of

four key elements through which a learner cycles in a continuous spiral of learning. The four elements are (i) exposure to a concrete experience, (ii) reflection on that experience, (iii) generalization of the experience and formation of abstract concepts based on the generalization, and (iv) application of these concepts to the concrete experience. In an experiential interactive learning environment, the concrete experience is replaced with a simulated world, and the learner interacts with it, causing the simulated world to change.

4 An Example

The chapter of Logistics Simulation is designed to give students the opportunity to practice using the skills and knowledge from Logistics. Simulation can be an extremely powerful tool and is becoming quite widespread, yet few in industry seem well trained in the design, implementation and interpretation of a useful simulation experiment.

Table 1 Operation Chart of a Gear Processing Line

Line				Shifts	Daily Capacity	Cycle Time	Batch	Production Rhythm	Operation Period	Yield								
Gear Processing				2	320	3min	1	3min	2H	40

The simulation model in figure 2 is an example on the software of FLEXSIM, which can show the various changes of WIP to students.

Figure 2 Simulation Model on FLEXSIM

5 Conclusions

The primary intention of this paper was to present a simulation model that facilitates manufacturing process experience. The overall goal is to meet the logistics challenges in sustaining today's complex manufacturing systems, many of which are expected to have higher productivity. Although facilitating experiences of students is important, it is not an adequate approach for designing meaningful problem-based learning environments. Future research consists of implementing, testing and evaluating the learning effectiveness of the logistics experience. In addition, there are plans to enhance the technology infrastructure – additional features, multi-learner capability and experience development tools.

Analysis on Impact of China's Stock Index Futures on Stock Market Liquidity

Hao Guiyan

Graduate School, Wuhan University of Technology, Wuhan, P.R.China, 430070

(E-mail: haoguiyan@163.com)

Abstract: This article uses exchanging volume, relative prices, and yield volatility of the daily trading data of the CSI 300 index as indicators to measure its liquidity and makes empirical analysis to analyze the impact of the introduction of stock index futures on the liquidity of spot market. Through study we found that the introduction of stock index futures market had a crowding-out effect on the spot market in the short term, thus reduced the liquidity of the spot market. But in the long term, the stock index futures attracted plenty of outside capital with its funds attracting effect, and the spot market showed a gradually increasing trend in liquidity.

Key words: Stock index futures; Stock market; Liquidity

1 Introduction

“The launch of the stock index futures in China is first to solve the liquidity problem.” said Leo Melamed, father of the global financial futures and lifelong honorary chairman of Chicago Mercantile Exchange. Based on conceptual and empirical analysis of the impact of CSI 300 index futures on the stock market, we arrived at the current liquidity situation of China's stock market. China Financial Futures Exchange officially launched the CSI 300 stock index futures contracts on April 16, 2010, according to its basic properties of the stock index futures, its launch undoubtedly have a huge impact on China's securities market^[1]. Therefore, it is an important issue to discuss whether the introduction of stock index futures is necessary to promote the development of China's stock market.

2 Theoretical Analysis of Stock Index Futures' Impact on Stock Market Liquidity

2.1 Theoretical model of impact of stock index futures on the liquidity of stock market

Subrahmanyam (1993) introduced liquidity variation of stock market through analyze the liquidity risk before and after the introduction of stock index futures, and his theoretical model is as follows:

Before the introduction of stock index futures, the liquidity risk faced:

$$Var(d\phi) = Var(d\varphi) \quad (1)$$

After the introduction of stock index futures, the liquidity risk faced:

$$Var(d\phi + d\varphi) = Var(d\phi) + Var(d\varphi) + 2cov(d\phi, d\varphi) \quad (2)$$

Equation (1) - Equation (2) draw out:

$$Var(d\phi + d\varphi) - Var(d\phi) = (\sigma_\varphi^2 + 2k\sigma_\phi\sigma_\varphi)d_t \quad (3)$$

If equation (3) is greater than 0, then $k > -\sigma_\varphi / 2\sigma_\phi$, that means after the introduction of stock index futures, the risk that liquidity providers faced is bigger than before, naturally require more risk premium, leading to the decrease of liquidity of stock market. Conversely, if (3) is less than 0, $k > -\sigma_\varphi / 2\sigma_\phi$ means the liquidity of stock market increased after the introduction of index futures.

Therefore, whether k is greater or less than $-\sigma_\varphi / 2\sigma_\phi$ is the standard to measure liquidity changes in stock market after the introduction of stock index futures.

2.2 Impact of stock index futures on the liquidity of stock market

This paper argues that the liquidity of the stock index futures on the stock market is mainly manifested in the crowding-out effect and the absorb effect of the transaction, so the impact of stock index futures on the liquidity of stock market due to the result of the combined effect of both.

2.2.1 Crowding-out effect

The crowding-out effect refers to the introduction of stock index futures will attract funds in the stock market, thereby reducing the liquidity of the spot market. Such situation appeared in Japan after they launched the stock index futures, the funds of stock market were attracted by the stock index futures market, therefore decreased the exchanging volume in the stock market and resulting in liquidity decrease.

2.2.2 Attracting effect

Although the introduction of stock index futures would lead to liquidity decrease in the spot market, it also has the effect to attract incremental funding of over-the-counter, which is known as the attracting effect. As to the current situation of China, the insurance funds and the security funds and other large institutional investors only put part of their funds into the stock market, the scale of outside funds can be very large, if the introduction of stock index futures attracted these incremental funds into the market, it will make large contribution to improve liquidity of the stock market and the stock index futures market.

2.2.3 Analysis of the combined effect to liquidity

In the short term, due to the low margin, low-cost, high financial leverage, etc. of the stock index futures, it attracted certain number of institutional investors and fund managers which use them as hedging and arbitrage tools, thus the stock index futures set a crowding-out effect in transaction on the spot market. In the short term, the introduction of stock index futures has an effect of diversion funds in the stock market and leading to liquidity decline in the stock market. While in the long term, stock index futures owns the function of risk aversion, investors' willingness to put money in the stock market will increase in familiar risk situation, and the stock market can attract more incremental funds which can drive the market more prosperous. So, in the long term, there exists some complementary effect between stock index futures and stock market to some degree.

Through the above analysis, this paper argues that the stock index future has a declining effect prior to ascending effect to the liquidity of the stock market.

3 Empirical Analysis of Stock Index Futures' Impact on Stock Market Liquidity

3.1 Definition of stock market liquidity

Liquidity is a concept that hard to be distinguished, it almost related to all the factors in market operation. Keynes was the first to summarize the liquidity of an asset. He thinks that the liquidity of an asset means it can easily realized without any loss in the short term. It can be viewed from two perspectives: First, the realization ability of assets, which is the risk about the ultimate value; second, market absorption capacity, that means realize without losses. Therefore, liquidity means the ability of investors to trade quickly at a reasonable price which based on market supply and demand conditions. In the financial sector, a generally accepted definition of market liquidity is: investors can buy or sell large amount of stocks in their needs with very low transaction cost and causes little effect to the price, that means the market is with liquidity^[2].

3.2 Indicators selected in liquidity measure

From the existing literature, the methods of liquidity measure still lack standard to unify. Different starting point of research and different market microstructure lead to different liquidity indicators of measure.

By comparing the equilibrium of continuous auction and sequential auction, Kyle described characteristics of market liquidity systematically under the market-maker system, he thinks that liquidity mainly consists of the following:

Depth (depth), means absorbed exchanging volume which does not affect the current price condition, it can also refer to the number of delegations entrusted to a single market maker in a certain period of time. Better liquidity means that investors can buy or sell large amount of stocks in the current price. The more quantity of the orders, the more depth of the market, conversely, the market lacks depth.

Tightness (tightness), also known as the breadth, refers to the magnitude which the market price deviate from the equilibrium price, namely time cost required when reaching an exchange under certain conditions. The most widely used method to measure the tightness is the bid-ask spread. In the continuous auction equilibrium, the market is infinitely tight, trading a certain amount of stock is very fast, almost no cost^[3]. While in the sequential auction equilibrium, the auction is not continuous, and the market is not infinite tight, therefore, the transaction cost is an increasing function of the transaction time.

Resiliency (Resiliency), refers to the loss rate of price fluctuations which caused by the transaction, or the adjust rate of order imbalance, namely the convergence speed of price to the real price of the asset. The more flexible the market is, the faster the prices returned after deviate from the value. Academia do not have a unified metric about the market resiliency, one of the methods is to measure the difference between the current best seller and the next best seller, the smaller the spread of the two orders, the shorter the time required to return, and thus lead to more market flexibility.

3.3 Empirical analysis of impact of the CSI 300 index futures on the A-share market liquidity

The indicators selected in measuring market liquidity above are too singular. This article chooses

three indicators: the exchanging volume, the relative price spread, and the yield volatility to measure the depth, tightness, resiliency of liquidity respectively to avoid biased study results and thus to obtain a more accurate result.

3.3.1 Exchanging volume:

Measure the volume or turnover of transactions in a certain price range.

$$V_q = \sum_{i=1}^n M_i^t \tag{4}$$

$$V_m = \sum_{i=1}^n M_i^t P_i^t \tag{5}$$

In these function, V_p stands for exchanging volume, V_m for turnover, M_i^t for the volume of ith transaction in period t, P_i^t for the price of ith transaction in period t

The sample selected in this article is the exchanging volume of the CSI 300 Index; the study period is from September 17, 2009 to November 16, 2010. September 17, 2009 to April 15, 2010 is the period before the launch of stock index futures; April 16, 2010 to November 16, 2010 is the period after. All data were from the Star site securities, and Djinn financial platform database. The figure below shows the changes of exchanging volume after the introduction CSI 300 stock index futures:

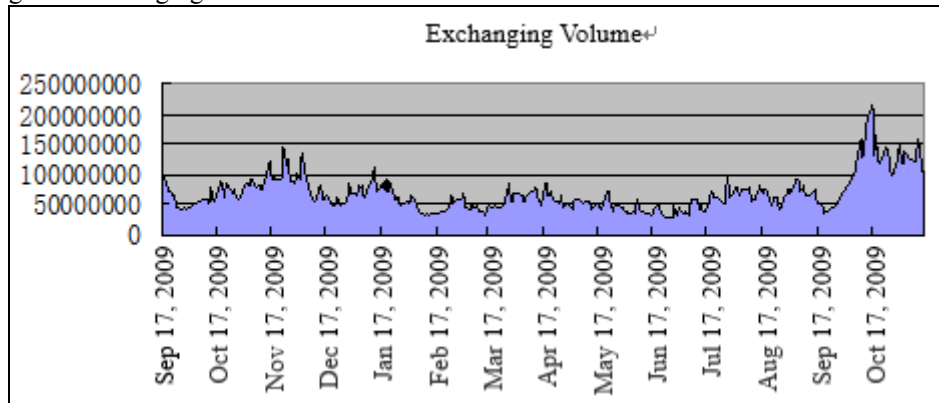

Figure 1 Exchanging Volume after the Introduction CSI 300 Stock Index Futures

Figure 1 shows that, before the launch of the CSI 300 stock index futures, the Shanghai and Shenzhen 300 stock market turnover is basically fluctuated between 3000000-1500000000, its volatility is relatively stable; after the launch of CSI 300 stock index futures, the exchanging volume decreased gradually from the launching day(April 16, 2010) to June 30, over time, after July 2010, the exchanging volume gradually increased and so did its volatility, which indicates that the liquidity was increasing rapidly.

Based on the above figure, the liquidity declined due to the crowding-out effect at the beginning of the introduction of stock index futures, but over time, the liquidity gradually increased in responding to the absorb effect, which indicates the CSI 300 stock index futures has a declining effect prior to ascending effect to the liquidity of the stock market.

3.3.2 Relative price spread

Refers to ratio of the middle price and the spread between the lowest and the highest selling price in the current market, which is the most basic measure of liquidity, and can be calculated as:

$$R_t = \frac{p_t^h - p_t^l}{[\frac{p_t^h + p_t^l}{2}]} \tag{6}$$

In which, p_t^h and p_t^l each stands for the highest and the lowest price of stock in day t.

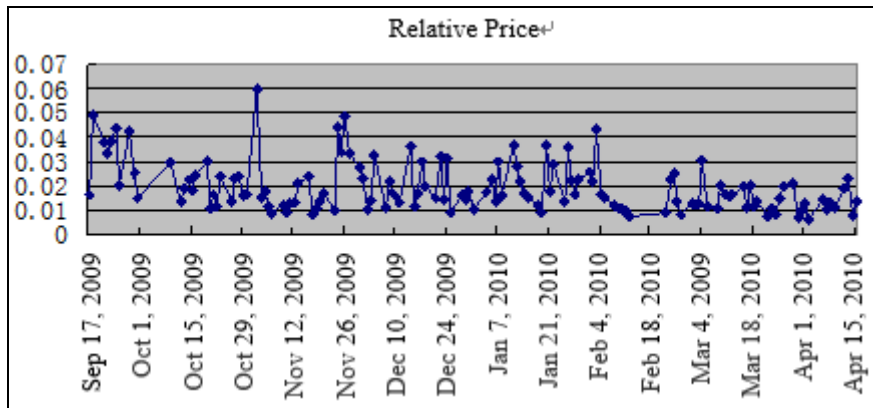

Figure 2 Relative Price Spread of CSI 300 Index in Period 1

The sample selected in this article is both the highest and lowest daily prices of the CSI 300 Index, from September 17, 2009 to November 16, 2010 and this duration was divided into period 1 and period 2 according to it is before or after the launch of the CSI 300 Index, period 1 is from September 17, 2009 to April 16 2010, period 2 is from April 16, 2010 to November 16, 2010. According to formula ③, relative spread of CSI 300 Index can be figured out, the results as shown in Figure 2 and Figure 3^[4];

Figure 3 Relative Price Spread of CSI 300 Index in Period 2

It can be figured out by comparing Figures 2 and Figure 3 that the stock market fluctuates a lot before the introduction of the CSI 300 stock index futures, the relative spread of the CSI 300 Index was once up to 0.06, and reached 0.05 twice, but it was under 0.05 and with less fluctuations from the launching day to the last day of the study period, thus according to the above theoretical analysis, the transaction cost declined to its minimization in this period, indicating that the liquidity of stock market has been significantly enhanced after the introduction of the CSI 300 Index stock futures.

3.3.3 The volatility of yield

Following the volatility of the stock investment yield is discussed. Obviously, the random price volatility of stock with high liquidity is very small, and so did the yield volatility in normal trading. The main factor which affecting the yield volatility is the relative variation of the exchanging volume^[5], if the relative variation in the exchanging volume have little impact on the yield volatility, namely the variation of exchanging volume causes small price change, it means the liquidity is rich, and vice versa, if the relative variation in the exchanging volume showed great impact on the yield volatility, it means the liquidity is poor. Therefore, this paper will use the impact of relative variation in the exchanging volume on the yield volatility to measure stock market liquidity.

(1)The stock yield: logarithmic difference of the discrete price, its formula as follow:

$$r_t = \ln(p_t) - \ln(p_{t-1}) \tag{7}$$

In which, p_t stands for the closing price of the index in period t, p_{t-1} for the closing price of the index in period t-1, r_t for return rate in period t.

(2)The relative variation of the exchanging volume: the proportion of volume increment in the original volume, can be calculated as:

$$v_t = \left| \frac{V_t - V_{t-1}}{V_t} \right| \quad (8)$$

In which, V_t stands for the exchanging volume in period t, V_{t-1} for the exchanging volume in period t-1, v_t for the relative exchanging volume in period t.

(3)We established the regression model of yield and the relative volume, the coefficient reached can be seen as a measure index of liquidity. The equation is as follows:

$$r_t = \alpha + \beta v_t + u_t \quad (9)$$

According to the model (9), we examined the liquidity variation in 7 months both before and after the introduction of the CSI 300 stock index futures, in which β is an indicator to measure the liquidity [6]. Obviously, the coefficient is small, the price change involved by the volume is small too, which means the liquidity is rich.

Use the Eviews software to process a regression analysis on the yield and relative daily exchanging volume of CSI 300 index, the results are as follows:

$$\begin{aligned} \text{Before listed: } r_{it} &= -0.00014 + 0.01528 v_{it} + u_{it} \quad (10) \\ \text{s.e} &= (0.0013) (0.0058) \\ \text{t} &= (0.1097) (2.6214) \end{aligned}$$

$$\begin{aligned} \text{After listed: } r_{it} &= -0.00011 + 0.01362 v_{it} + u_{it} \quad (11) \\ \text{s.e} &= (0.0014) (0.0056) \\ \text{t} &= (0.0803) (2.4001) \end{aligned}$$

Through comparing expression (10) and (11), we can see in the 7 months both before and after the launch of CSI 300 stock index future, the value of β in expression (10) which before listed is 0.001528, and in expression (11) which after listed is 0.01362, it is clear that the value of β after listed is smaller than the value before listed, the liquidity indicators were declined on the spot market, indicating an increase in liquidity.

4 Conclusions

4.1 Conclusions

This article uses exchanging volume, relative prices, yield volatility of the market as indicators to measure depth, tightness and resiliency of liquidity and analyzes the impact of the introduction of stock index futures on the liquidity of spot market, through the above empirical research and analysis, we can draw the following conclusions:

1. Based on the analysis of the exchanging volume of the stock market both before and after the introduction of the CSI 300 stock index future, we figured out that in its initial listing, the CSI 300 stock index future was kind of substitution to the stock market in some degree and may generate funds crowding-out effect^[7], fund managers and speculators who values index a lot, will be transfer part of their funds to the future market, thus decreased the liquidity of stock market, but this phenomenon is temporary.

Through analyzing variation of stock index to the relative price and establishing regression model of the stock yield and relative exchanging volume, and through comparing relative parameters we found that: In the long term, the stock index future owns the advantage of hedge, high leverage and flexible, it attracted a large number of arbitragers and hedgers, and make outside capital flow into the market, and thus to increase liquidity of the stock market, so the introduction of stock index futures plays a long-term role in promoting the development of the stock market.

4.2 Policy recommendations

Stock index futures is a double-edged sword, if we lack effective means to control the risk after the introduction of it, the risk would turn into loss in reality, and even increase the risk of the entire capital

market. According to the conclusions above, the author give policy recommendations as follows:

The first is to establish and improve the supporting regulatory measures. As to the experience of some developed countries, they have formed a certain pattern for the risk management of the stock index futures, and also an impeccable management system. China can learn from the experience of the developed countries about risk management of the stock index futures market, continue to use the three-stage regulatory model, the government - China Futures Association - Futures Exchange, for risk regulation^[8]. The three stages complement and cooperate with each other, and together to ensure normal and standardized operation of China's stock index futures market, to maintain the fairness and openness of the transactions, thus to promote the healthy development of the futures market.

The second is to improve the risk management of micro-level in stock index futures market. The micro-level mainly refers to transaction subjects including investors and brokerage firms. Firstly, the futures brokerage firms should scrutinize the customer's qualification, funding sources, and credit status stringently; enforce management system of customer margin strictly; strengthen internal supervision and enhance professional ethics education of staff, and improve the system of settlement and risk management. Secondly, investors should enhance their master of risk, fully grasp the knowledge and skills in trading stock index futures and enhance their predictive ability, reduce the transaction risk through more flexible means.

Abstract: In the mixed assembly line production, different production have different cycle time and the same product in different process have also different cycle time. Therefore, waiting time in the process of production and even the accumulation of articles will appear. In order to reduce the waiting time, this paper will apply the methods of heuristic algorithm-Palmer and NEH into the formulation of production plan by taking BSH production plan as an example. Finally, the witness analogue simulation will verify the applicability of heuristic algorithm.

Key words: Heuristic algorithm; Production plan; System simulation; Balanced production

1 Introduction

In manufacturing enterprises, mixed production is a sort of production mode which is generally used and adapted to market. The production mode is fulfilled through a scientific arrangement of a number of product varieties which share the similar process flow and production methods in the production sequence, in which a continuous production is rhythmically and proportionally proceeded. And its varieties, outputs, cycle time, equipments should be in conformity with comprehensive and balanced the premise of the production pattern.^[1] Multispecies mixed-model production is mainly suitable for the enterprises which could undertake assembly line production and mass production in which the machining process is basically same; the production equipment do not need to be adjusted; and the tools, molds, fixtures can be rapidly transferred. The method of mixed production mainly include the heuristic method, the proportion method, the logic method and the branch-bound method.

Located in Suzhou industrial park, the products of BSH company mainly include MS, BE&ED, PP ECU, ABS, PS. Each kind of products can be divided into various types. PP ECU only has one product model, that is, PP – Sensor whereas MS is composed of ten types of products which is claimed as the

most productive model. As the earliest product, MS owns a strong technical support in BSH company and exerts great influence on capital operation and profit of the company. The paper will take MS as an example based on the research of BSH company production plan^[2].

According to customer requirements, a balanced production plan is developed. As shown in table 1.

3 Application of Heuristic Algorithm

In manufacturing process, MS products will mainly proceed three procedures: SMT, ICT and Milling. Due to the different production rhythms, the production will produce waiting time during the process of production. Therefore, our target is also to reduce the waiting time during producing as much as possible. In the production process, appropriate adjustment of production order can decrease the possibility of waiting time. As for the sequence of production, the heuristic algorithm can be used to achieve the purpose of operational research. Now, taking MS production as examples, the heuristic algorithm is applied to sort the balanced production plan of the daily production plan^[3-4].

Taking the practical problems as a target object, heuristic algorithm is a method of judging and solving or a strategy to solve practical problems. Heuristic algorithm doesn't have a standard operation procedure, for its solution is by the previous experience and the accurate judgment of an actual situation. It is not mechanical in solving practical problems. Therefore, it fully embodies the human factors and plays to people's creativity and initiative. Hence, heuristic algorithm is a more humanized and user-favored flexible method^[5].

Aiming at the optimization problem of SMT production assembly line, which is also sorting problem of SMT-ICT-Milling, optimization algorithm of $n/3/F_{\max}$ problem. Based on the practical situation of BSH company, this paper applies simpler and more practical Palmer algorithm and NEH algorithm to sort the assembly lines, meanwhile, through the sequence of daily production in a set of balanced plan to save working time and fund.

1) Palmer algorithm was proposed by D.S. Palmer in 1965. Its calculation is on the basis of the slope index of the workpieces in solving the problem of assembly line. After calculating the slope index and sorting in an index decreasing, a satisfied result can be obtained. Calculation of Slope index is as follows:

$$\lambda_i = \sum_{k=1}^n [M_k - (n+1) / 2] p_{ik} \quad (1)$$

According to the sorting of the workpiece λ_i without increasing, can get satisfying sequence.

n —Machine number;

M_k —Machine k , $k=1,2, \dots,m$;

p_{ik} —Processing time on the machine of workpiece i .

According to the arrangement of the workpiece λ_i in descending order, a satisfactory sequence can be obtained.

2) NEH method was proposed by M.Nawaz and E. Enscren in 1983. The concrete procedures of NEH method are as follows:

The first step, calculating the total processing time P_i of each workpiece i :

$$P_i = \sum_{j=1}^m p_{ij} ; \quad (2)$$

The second step, according to the sorting of P_i without increasing, getting sequence T ;

The third step, choosing the top two workpieces in sequence T . The two workpieces can be composed of two kinds of sequence order. By calculating the longest completion time of the C_{\max} of the two and choosing the small of C_{\max} arrangement, the relative position of the first and the second workpiece can be determined. Put this order in a new sequence S : For $t = 3$;

The fourth step, choosing the workpiece of t in sequence T , putting it in sequence S , calculating C_{\max} under three kinds of order and selecting minimum order of C_{\max} into S .

The fifth step, if $t < n$, for $t=t+1$. Returning to fourth step. If $t=n$, then turn to sixth step;

The sixth step, the S sequence is the satisfactory sequence.

In the process of calculation, assume that all products through the SMT are manufactured in L1 and all conducted on Milling1 when cutting board. (BET is a special product which does not need to test, it can be specially considered. This sorting does not consider the special BET products.) Take day as the unit to determine the production order every day.

Take the products of Table 1 as examples by using Palmer algorithm and NEH algorithm to sort. Cycle time statistic datas of 9 kinds of products in Date1 in SMT, ICT, Milling are shown in Table 2.

Table 2 Cycle Time in Various Processes

production	number	SMT cycle time(s)	ICT cycle time(s)	Milling cycle time(s)
1038301904	270	34.1	26	24.8
1038305220	290	36.1	26	24.8
1038301465	260	27	14.5	20.6
1038301499	260	24.9	14.5	20.6
1038301756	210	29.2	18	20.6
2228300748	170	21.8	16.5	20.6
2228300555	170	19.5	14	27.1
1038301376	100	35.1	26	24.8
1038301412	100	41.2	26	24.8

1) Arranging production order according to Palmer algorithm.

First, calculate λ_i of each product according to Palmer algorithm. (It is noted that the P_{ik} time needs to be unified. For the convenience of calculation, this time takes seconds as the calculation unit λ_i) Then arrange production order in diminishing λ_i , and the sorting result is: 555, 748, 376, 499, 465, 412, 756, 904, 220.

2) Arranging the production sequence in light of NEH algorithm.

(1) Calculating the total processing time of each model P_i , According to descending order .

Getting $T = (220, 904, 465, 499, 756, 555, 412, 748, 376)$

Calculate the C_{max} of sequence 220, 904 and sequence 904,220, then choose the smallest C_{max} , and get the relative position of two types of products is: 904, 220. Put 904, 220 in the sequence S. Evaluated in order, the order of 9 types of products in sequence S is as follows: 465, 904, 220, 555, 499, 412, 376, 748, 756.

In summary, By Palmer algorithm for sorting result is as follows : 555, 748, 376, 499, 465, 412, 756, 904, 220.

By NHE algorithm for sorting result is as follows: 465, 904, 220, 555, 499, 412, 376, 748, 756.

4 Use Witness Simulation to Select the Optimal Solution

Table 3 The Definition of Entity Elements

Element name	Type	Number	Instruction
A	Part	1	1038301904 (904)
B	Part	1	1038305220 (220)
C	Part	1	1038301465 (465)
D	Part	1	1038301499 (499)
E	Part	1	1038301756 (756)
F	Part	1	2228300748 (748)
G	Part	1	2228300555 (555)
H	Part	1	1038301376 (376)
J	Part	1	1038301412 (412)
Machine001	Machine	1	SMT Machine Group
Machine002	Machine	1	ICT Machine Group
Machine003	Machine	1	Milling Machine Group
Buffers001	Buffer	1	SMT Input Buffer
Buffers002	Buffer	1	ICT Input Buffer
Buffers003	Buffer	1	Milling Input Buffer

Now we use witness to verify the applicability of the Palmer algorithm and NEH algorithm. First of

all, establish witness simulation model on production processes of production^[6-7].

Witness is a practical simulation software system, it can simulate many kinds of continuous system or discrete system. Witness is introduced by Lanner of England, which is loved by peopel due to its powerful function. So far, many countries have already maked better use of Witness,which also has been applied into the projects of international logistics optimization, process improvement, system optimization and so on. Using Witness to simulate the production plan, this paper compares the circumstances before and after the heuristic algorithm. Thus a better production plan will be obtained^[8].

1) Firstly, get the required production time of these 9 types of products after fully SMT-ICT-Milling, by simulating the original sorting of Date 1.

Define the elements, as shown in Table 3.

Design the Part element, as shown in Table 4.

Table 4 Detailed Design of Product in General

Product name	904	220	465	499	756	748	555	376	412
Arrivals Type	Active	Active	Active	Active	Active	Active	Active	Active	Active
Inter Arrival	3	3	3	3	3	3	3	3	3
Lot Size	270	290	260	260	210	170	170	100	110
First arrival	0	1	2	3	4	5	6	7	8
Maximum	270	290	260	260	210	170	170	100	110
To. . .	Push to ROUTE	Push to ROUTE	Push to ROUTE	Push to ROUTE	Push to ROUTE	Push to ROUTE	Push to ROUTE	Push to ROUTE	Push to ROUTE

Model simulation clock from the system default of 1 time units for 1min running, click Run in the Witness menu and run the simulation model. Finally it concludes that the total production time of a day's production plan needed is 947.84 min.

2) Simulate the sorting results after Palmer algorithm:

At this moment an adjustment is needed after the rearrangement of the General details of product design. The details of the design after sorting is shown in Table 5.

Table 5 Detailed Design of Product in General after Order in Palmer

Product name	904	220	465	499	756	748	555	376	412
Arrivals Type	Active	Active	Active	Active	Active	Active	Active	Active	Active
Inter Arrival	3	3	3	3	3	3	3	3	3
Lot Size	270	290	260	260	210	170	170	100	110
First arrival	7	8	4	3	6	1	0	2	5
Maximum	270	290	260	260	210	170	170	100	110
To. . .	Push to ROUTE	Push to ROUTE	Push to ROUTE	Push to ROUTE	Push to ROUTE	Push to ROUTE	Push to ROUTE	Push to ROUTE	Push to ROUTE

Table 6 Detailed Design of Product in General after Order in NEH

Product name	904	220	465	499	756	748	555	376	412
Arrivals Type	Active	Active	Active	Active	Active	Active	Active	Active	Active
Inter Arrival	3	3	3	3	3	3	3	3	3
Lot Size	270	290	260	260	210	170	170	100	110
First arrival	1	2	0	4	8	7	3	6	5
Maximum	270	290	260	260	210	170	170	100	110
To. . .	Push to ROUTE	Push to ROUTE	Push to ROUTE	Push to ROUTE	Push to ROUTE	Push to ROUTE	Push to ROUTE	Push to ROUTE	Push to ROUTE

Click Run and get the operation time: 925.18 min which saves 22.66 min and production expenses 143.75 yuan as well (wages for employees and depreciation of machinery).

3) Simulate sorting results after NEH algorithm:

An adjustment is needed after the rearrangement of the General details of product design. The details of the design after sorting is shown in Table 6.

Run again and get the total processing time: 909.27 min which saves 38.57 min and production expenses 244.68 yuan.

Comparing the results of sorting after Palm algorithm with NEH algorithm, the result is that sorted by NEH algorithm is superior to Palmer's. Thus it can be seen that the applicability of NEH algorithm in scheduling of production of BSH company.

5 Conclusions

The production plan of enterprise is the primary function of enterprise production management, the provisions of the enterprise production in the planning period, the model number, quality and customer delivery rate, is also to complete the production goals for the enterprises in the planning period, an important link in improving economic efficiency of enterprises. The focus of this paper is that using the heuristic algorithm to sort the production plan, and improve the customer delivery rate^[9-10]. This paper uses heuristic algorithms-Palmer algorithm and NEH algorithm to sort the production sequence and use witness simulation to verify the applicability of the two algorithms. If there is any other better ways to apply in the production plan will be the further exploration targets.

Research on the Correlation of Financial Innovation and Economic Growth

Liu Caijie

School of Foreign Languages and Literature, Wuhan University, Wuhan, P.R.China, 430072
(E-mail: ljf198266@163.com)

Abstract: Financial innovation is seen as an inevitable product of the development of financial activities, which provides new impetus for the development of financial activity. Financial innovation has played a very important role in the process of modern economic growth. This paper expounds the connotation and the main cause of financial innovation which systematical analyzes the relationship between financial innovation and economic growth. Besides, it makes a quantitative calculation and then analyze on the correlation between financial innovation and economic growth through statistical analysis and function-fitting method which can clearly show the relationship between them when combining the qualitative analysis with the quantitative analysis method.

Key words: Financial innovation; Economic growth; Correlation; Function fitting

1 Introduction

Financial innovation is the act of creating and then popularizing new financial instruments as well as new financial technologies, institutions and markets. Financial institution or financial regulatory authorities make use of the new ideas, new technologies, new managements, new organizational forms, etc., regroup the various elements within the financial sector, in order to achieve the optimal coordination of micro and macro benefit. It is the inevitable outcome of the process of the development of social economy and finance, which has played an active role in the business scope of financial institutions, strengthening the role of economic lever of interest rates and the promotion of financial liberalization. Financial innovation has a strong force which has brought a qualitative change in the financial system and the future development through the reorganization of financial elements. Meanwhile, financial innovation activities can not only increase the flow of funds but also change the flow of funds. In this sense, financial innovation is the driving force behind economic growth and the pilot strength in promoting economic development. As the liberalization, internationalization, and the acceleration of integration process of the world's financial markets, as well as new technological revolution, especially the modern computer and information technology widely used in the financial sector, the world economy and finance present the trend of globalization. Then the study of financial innovation is also necessary since it not only promotes economic growth, but also helps to play the role of finance in economic development, maintaining the virtuous circle of finance and economy. The lacking of financial innovation will not only restrict the development of Chinese financial industry, but also limit the development and function expansion of Chinese business. Therefore, the research on the correlation of financial innovation and economic growth is of great theoretical and practical significance.

2 Financial Innovation Theories

In the history of the development of the world economy, innovation has always been the driving force. What's more, the every climax in the process of financial development is launched by the financial innovation, and every upgrade of financial development is driven by the financial innovation.

2.1 The connotation of financial innovation

Financial innovation is the re-combination of various elements in the financial sector. It refers to the reforming and creative activities on institutional settings, variety of businesses, financial instruments and institutional arrangements conducted by financial institutions and financial regulatory authorities. They mainly pay attention to the micro- and macro- interests. Financial innovation can be divided into narrow innovation and broad financial innovation: the narrow financial innovation refers to the innovation of financial instruments; the broad innovation refers to the adaption to the economic development needs, which creates new financial markets, financial products, financial systems, financial institutions, financial instruments, financial methods and financial regulation modes.

2.2 The incentives of financial innovation

The main purpose of financial innovation is to improve the competitiveness of financial institutions, financial efficiency and to optimize the allocation of resources. The theory of financial innovation incentives analysis is based on the analysis of the purpose of financial innovation:

2.2.1 Technical progress theory

Technology progress theory believes that the widely use of high-tech in the financial industry, such as that the telecommunications, computer technology, Internet and e-commerce promotes the rapid development of the electronic in Financial industry and financial networks. The incentive is that these new technologies greatly reduce the time and space distance of financial transactions, accelerate the transfer of the funds, reduce the financial transaction costs and improve the efficiency of financial markets and management level. They believe that technological innovation is mainly limited by three variables:

- 1) The degree of competition
- 2) The Scale of enterprise
- 3) The power of monopoly

2.2.2 Constraints theory

The Theory of Constraints believes that financial innovation is the response of financial institution to get rid of or reduce the constraints applied to them. External constraints come from the competition in the financial industry, the financial controls imposed by the government, the service cost that consumers wish to pay, etc. The internal constraints come from the liquid assets ratio, capital ratio, return on assets, growth and other targets formulate by financial firms themselves. As long as these constraints changed and presented the profit opportunities after deducting the cost of financial innovation products, financial firms will try to innovative.

Scholars who agree with the theory of constraints stressed that the financial regulation imposed by government is an important reason for induced financial innovation. They think that even in a market economy country, regulations that formulated by the government in the financial sector is relatively the most serious. Some financial companies “explore loophole” to circumvent them because some regulations limit the profitability of the financial industry. When the financial regulatory constraints large enough to increase operating profits if avoiding them, financial innovation that “explore loopholes” is very likely to occur. This form of innovation is called financial innovation which evades regulation.

2.2.3 Demand theory

The viewpoint that demand induced financial innovation believes that every financial product has different characteristics (such as duration, profitability, liquidity, risk, security, etc.) which analyze from the point of investors. As the economic environment changes, the investment preferences will change and result in the new financial products. The emergence and widely use of new financial products, new technologies and new financial market is because of demand. The innovation will be successful once both investors and fund-raisers find some demands that can meet through the financial innovation. Investors demand for new financial products for many reasons and two of them are the most important:

1) The demand for avoiding risks. The risks faced by investors in financial markets are exchange rate risk, interest rate risk and credit risk, etc. The degree of these risks changes with the changing economic environment. Then, they induced the demand of new financial products to avoid these risks.

2) The demand for the liquidity and profitability of the financial products. The raising of inflation rates and nominal interest rates improved the opportunity cost that without the burden of interest. Besides, it makes the traditional financial more difficult to accept an alternative between the liquidity and profitability, leading the demand for new financial products that can improve liquidity and profitability.

2.2.4 Regulatory theory

The viewpoint of regulation induced financial innovation thinks that the foundation of financial system is due to the competition between financial authorities. For governments or monetary authorities, the aim is to protect their own interests and realize their customers' welfare maximization at the same time. When the monetary authorities compete with each other, trying to maintain their loyal customers, it will deregulate or introduce new measures which are more relax, thereby contribute to the financial innovation. Fundamentally speaking, financial innovation is a kind of activity that for the monetary authorities to stabilize the financial system and to prevent uneven distribution (such as the reform of financial regulation, deregulation, etc.) At the meantime, it can induce the broader financial innovation.

3 Analyses on the Relationship of Financial Innovation and Economic Growth

3.1 Financial innovation promote economic development

1) Financial innovation makes financial industry more powerful to promote financial development and economic growth:

Financial innovation directly promotes the economic growth through the financial system risk management capabilities, information revealing, corporate governance, savings mobilization capabilities and easy exchange five functions. Through risk management functions, we can facilitate the aggregation, transactions and avoidance of the risk. What's more, we can spread the risk, change resource allocation and savings rate, reduce information cost and transaction cost, promote technological innovation and economic growth; financial innovation can reduce the individual economic information collection and processing cost, promote the efficient allocation of social resources and economic growth through information revealing function.

2) Financial innovation broadens the financial functions, facilitate the social investment and promote economic growth. Comprehensive financial increased the number of financial products and financial services, broadened the scope and expanded the ways to collect funds for financial institutions. Therefore, the financial industries' ability to collect money and improve profitability is enhanced. It also contributes to the tremendous growth in assets. In the mean while, a variety of convenient capital investment arrangements make marginal revenue increased. Then, the result of the comparison between capital cost and marginal efficiency can be changed and finally contributes to economic growth.

3) Financial innovation makes great contributions to the economic growth through the innovation of financial institutions, financial markets, financial services, financial systems and other aspects. In the most time, financial innovation use the approach of securitization and marketization which makes the rise of the status of the financial markets and the diversification of the allocation of financial resources. It goes without saying that it will promote the economic growth. What's more, financial innovation can improve the operational efficiency of financial markets, strengthen the leverage of interest and make the interest rate gradually toward liberalization. The quick react of the price in financial market to all information which can further enhance the reasonableness and price mechanism counts on the degree of modernization and internationalization in financial markets.

3.2 Economic growth promotes financial innovation

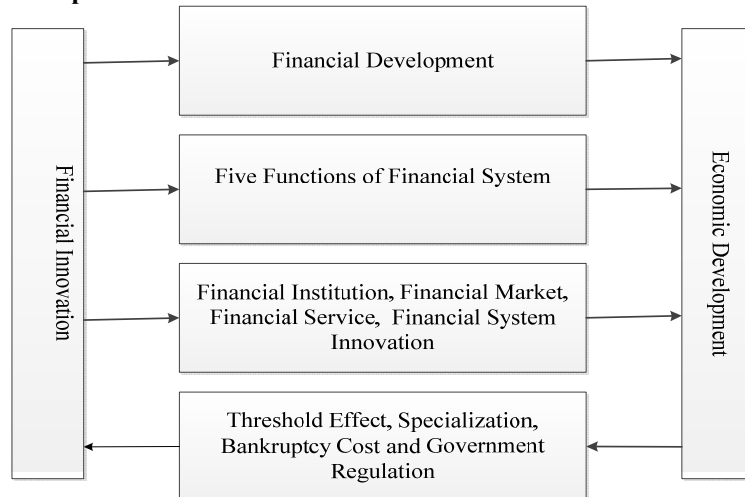

Figure 1 Relationship of Financial Innovation and Economic Development

Economics and finance conducted primarily through three channels: interest rates, prices, credit. Financial assets through interest rates and exchange rates affected investment and net exports, and ultimately affect output; financial assets have an impact on investment and consumption through financial asset price and wealth effects. The rising in interest rate or falling in financial asset price will cause the falling in investment and borrowing ability of corporate. It will further lead finance deficit and less spending of residents, eventually lead the falling in output. Financial innovation led the increase in financial asset classes and decline in transaction cost. It also sped up the transformation between assets and improved the sensitivity of credit, interest rates and asset price. In addition, with the complication

and specialization of financial innovation, economic activity and technological innovation will have different levels of impact in the financial system. There are four kinds of impact of economic growth on financial innovation: The existence of threshold effect makes economic growth and per capita income growth become the intrinsic motivation of the development of financial system. Capital accumulation helps motivate financial intermediaries take more detailed specialization, cost reduction and efficiency improvement; the increase in bankruptcy cost caused by the expanding of production scale will affect and the choice of financing channels and production technology of entrepreneurs, eventually motivates the emergence and development of stock market. Along with economic development, the government will regulate the financial industry and the regulatory approach is constantly changing. Finally, it will lead to financial innovation activities in financial industry.

In short, financial innovation and economic growth have a mutual relationship, financial innovation promotes economic growth and economic growth promotes financial innovation. The relationship is shown in Figure 1.

4 The Mathematical Analysis on the Association of Financial Innovation and Economic Development

4.1 Data collection and instructions

The data in this model contains GDP, consumer spending, the currency depth of whole social investment, human resources, total import and export, etc. In addition, the data sample collected from the national statistic. It describes the correlation of financial innovation and economic development. As is shown in Table 1.

Table 1 National Statistics

	2007	2008	2009	2010	2011
GDP (billion Yuan)	265810.3	314045.4	340940.2	401512.8	472881.6
Total social investment (billion Yuan)	137323.9	172828.4	224598.8	251683.8	311485.1
Imports (billion Yuan)	73300.1	79526.5	68618.4	94699.3	113161.4
Exports (billion Yuan)	93563.6	100394.9	82029.7	107022.8	123246.6
People spending (billion Yuan)	93317.2	111670.4	12358.6	140758.6	164945.2

4.2 Mode analysis

4.2.1 Analysis on the Correlation of GDP and Total Social Investment

First, make the fitting analysis on the data of GDP and investment, and then draw their relevance.

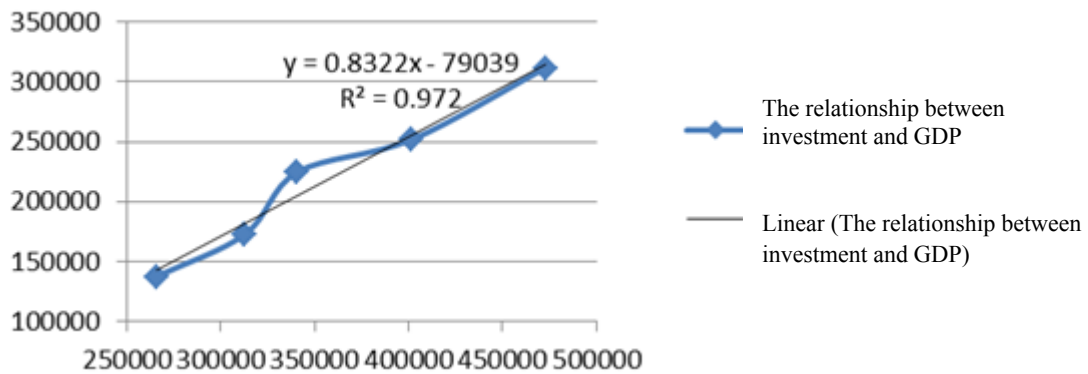

Figure 2 Correlation of GDP and Investment

The linear degree is 0.986, basic linear correlation

4.2.2 Analysis on the correlation of GDP and total social consumption

First, make the fitting analysis on the data of GDP and consumption, and then draw their relevance.

Figure 3 Correlation of GDP and Consumption

The linear degree is 0.998, basic linear correlation.

4.2.3 The analysis on the correlation of financial innovation and economic growth

For the index of financial innovation, this article is designed based on the principle of simplicity, the main indexes are the followings: currency depth, banking efficiency, the increase of deposits and loans caused by the financial innovation. The formulas are as followings:

Incremental loans caused by financial innovation = Incremental consumption + Incremental investment – Incremental loans

Incremental deposits caused by financial innovation = Trade balance + Investment + Consumption + Incremental deposits - GDP

Bank efficiency = (Total loans * Lending rate - Total deposits * Deposit rate) / Total deposits

Specific calculations are shown in Table 2.

Table 2 Data of Financial Innovation Index

	2007	2008	2009	2010	2011
Incremental loans caused by financial innovation(billion yuan)	7821.7	10153.5	13657.5	13985.6	15236.9
Incremental deposits caused by financial innovation(billion yuan)	39005.3	68153.8	152229.9	123750.1	104736.9
Bank efficiency	0.9%	1.2%	1.3%	1.1%	0.6%
Currency depth	0.218	0.228	0.384	0.228	0.218

In this paper, I make a fitting function of incremental loans caused by the financial innovation with the bank's efficiency and economic growth, in order to represent the relevance of financial innovation and economic growth. Assuming that incremental loans caused by financial innovation all transformed into investment. This assumption can be established because consumer loans are almost completed by traditional financial means. In the mean while, assume that the improvement of bank efficiency is totally caused by financial innovation which involve product, technology and institutional innovations. The increase in loans caused by Financial innovation that totally translated into investment can be directly included in the current GDP, the result is 0.603 (weighted average), so the GDP growth should be 1.603 times. The data in Table3 can be obtained from the foregoing data.

Table 3 GDP Growth Caused by Financial Innovation

	2007	2008	2009	2010	2011
GDP growth caused by the increased innovative loans	12749.4	16550.2	22261.7	22796.5	24836.1
GDP growth caused by the bank efficiency	445.5	578.8	349.1	666.7	428.2
GDP growth caused by the financial innovation	13194.9	17129	22610.8	23463.2	25264.3

It can be calculated that GDP growth caused by financial innovation in the proportion of GDP per year, respectively 4.96%, 5.45%, 6.63%, 5.84%, and 5.34%. Visual display: GDP growth caused by financial innovation per year is relatively stable. We can get the correlation of financial innovation and economic growth by the fitting function of GDP growth and GDP over the same period.

Figure 4 Correlation of Financial Innovation and Economic Growth

From the above data model analysis, the linear degree is 0.908; there is a positive correlation between financial innovation and economic growth.

5 Conclusions

From the above, we can conclude that economy and finance have a close relationship in a country's economic growth. Reasonable and appropriate financial innovation can improve the operating efficiency of the financial system and optimize the allocation of resources. In the meanwhile, economic development can also promote financial innovation.

Innovation is the power of development, it is also the driving force for continues development of bank sector and finance system. Only when we comprehensive understand the mutual influence of financial innovation and economic development can we control the financial risk and promote the social development best. This paper is guided by statistics, financial theory, innovation theory and system theory. On the basis of the correct understanding and analysis of financial innovation, it analyzes the correlation of financial innovation and economic growth from the 'financial innovation promotes economic development' and 'economic development promotes financial innovation' two aspects. On this basis, it takes advantages of system analysis, quantitative analysis and specific data validation. Studies suggest that financial innovation and economic growth exist positively correlation.

Research on Innovation Development and Risk Prevention of Logistics Financial Business of Commercial Banks in Wuhan City Circle*

Wang Zhenqiong

Manufacturing Industry Development Research Center on Wuhan City Circle,
Jiangnan University, Wuhan, P.R. China, 430056
(E-mail: 571179050@qq.com)

Abstract: As a kind of financial innovation business among domestic commercial banks in China, logistics finance has been catching universal attention in both theoretical and practical sense. Based on analyzing the features, problems and risks revealed by commercial banks in Wuhan City Circle when they conducted logistics finance, the paper pointed out that commercial banks in Wuhan City Circle should upgrade the developing level of logistics finance and make innovations on logistics financial mode to avoid risks for its further development. Meanwhile, it concluded that the development of logistics financial business complies with the need of commercial banks in Wuhan City Circle on innovative development; and also the need of domestic industrial development and the competition trend of supply chain.

Key words: Commercial bank; Manufacturing industry; Logistics finance; Risk

1 Introduction

Logistics finance is the settlement and financing service provided by banks and third-party logistics enterprises to customers during the whole process of supply chain. By conducting logistics financial business, companies are able to manage and coordinate the movements of capital and credit effectively, realizing the organic unification of logistics, information flow and capital flow.

Logistics Finance has been greatly developed abroad, acting as the main support for small and medium enterprises on financing. Generally, the development of western logistics finance can be divided into three phrases: before the middle of 19th century, prosper of capitalism gave birth to the warehousing industry, and further more pushed forward the inventory financing business. This is seen as the primary mode of western logistics finance; from the middle of 19th century to 1970s, the creation and implementation of relevant laws clarified the legal relations among all parties involved in logistics finance, impelling logistics financial business to further development of inventory financing-centered and account receivable financing- assisted mode; starting from 1980s, market competition among single enterprises developed into competition among multiple supply chains, meanwhile, the supply- chain finance emerged right after this, leaving logistics financial business in a superior position. Logistics finance functioned by depending on the supply chains at that time, through the cooperation between logistics enterprises and financial institutions, it managed to apply focal enterprises on supply chain as its center and supporting point so that it can achieve capital injection into those down-stream enterprises among the focal enterprises and interconnect focal enterprises and down-stream enterprises as a cohesive unit to improve the competitive capacity and inherent value of the supply chain itself.

Logistics finance is a new-born and fast-growing industry sprang up in China. The domestic logistics financial business originated from domestic commercial banks' innovative practice on financial business, of which the pressing financing demands were the primary motivation of it. At the end of 1990s, the cooperation among foreign banks, world-renowned logistics enterprises and some Chinese companies, in the form of warehouse financial business offered by some international large-scale enterprises and domestic enterprises, made it possible for them to conduct logistics financial business. This served as an example for the development of domestic logistics finance. Hereafter, at the end of the 20th century, some Chinese-funded banks began to give it a shot, shifting their unfold warehouse financing to trade financing through the trade of multiple commodities. However, the development of domestic logistics finance was still under inadequate attention and still had not achieved unification. After the year of 2005, with the development of economy and the innovation in both financial industry and modern logistics industry, domestic logistics finance got to enter into a period of rapid expansion.

* This paper is supported by Key Research Base of Humanities and Social Sciences of College in Hubei Province— Manufacturing Industry Development Research Center on Wuhan City Circle.

Deemed as the innovative product of financial institutions, logistics finance has its own characteristic which lies in that banks no longer evaluate enterprises according to the aspect of their financial capabilities, they evaluate enterprises according to their financial capability, market position and efficiency of its supply chain management, etc. Banks mainly finance for the enterprises which conduct business and cooperate with focal enterprises on the supply chain directly. Banks converted their practice of evaluating only credit risks on individual enterprise to the practice of evaluating credit risks on both whole supply chain and its transactions. Through coordinative risk management on the whole supply chain, the contradictory relationship on loans, it is difficult for enterprises to get loans from banks and meanwhile banks are very stint about loans to enterprises, between enterprises and banks gets to be coordinated, which provides a new way of financing for small and medium enterprises; and meanwhile creates a new service offered by banks and provides a new revenue growth opportunity for third-party logistics enterprises as well. Logistics finance promoted the close and effective cooperation of banks, third-party logistics enterprises and small medium enterprises within the whole supply chain system, and it also reduced the risks exist in information transfer, logistics and supervision, etc. Moreover, logistics finance improved the efficiency of commodity circulation and also the efficiency of logistics in the whole supply chain, achieved the stable, swift and efficient circulation of logistics, capital flow and information flow. By achieving these, it improved the competitive power of the whole supply chain system.

2 Development Characteristics and Problems of Commercial Banks' Logistics Financial Business in Wuhan City Circle

2.1 Joint-equity bank oriented

The developed logistics financial business in Wuhan City Circle is mainly propelled by joint-equity banks. Wuhan branch of Guangdong Development Bank, Wuhan branch of Hubei Huaxia Bank and Wuhan branch of Shenzhen Development Bank carried out logistics financial business with distinctive features one after another.

Table 1 The Logistics Financial Business of Commercial Banks in Wuhan City Circle

Banks	Business Type	Business Features and Scale of Development
GDB (Guangzhou Development Bank)	1. Developed banking business such as manufacturer-retailer-bank, chattel mortgage and goods property mortgage successively since the year of 2003; 2. Developed logistics bank etc. banking business in 2005;	Specifically aimed at small and medium enterprises to develop personalized products. The "Goods Mortgage" and "Logistics Bank" have been very popular in manufacture industry-centered industries like retailing industry and circulation industry. There have been 11 cooperative regulating companies and 36 authorized circulation enterprises so far.
HXB (Huaxia bank)	1. Launched Automobile Logistics Finance in 2006; 2. Launched Win-Win Financing Chain in 2006;	1. Establish specialist department to achieve team marketing and mainly work for First Automobile Works and Dongfeng Motor Cooperation. There had been more than 120 automobile raw material and parts suppliers, auto makers and auto dealers offering a capital of more than 13 billion RMB in the whole supply chain. 2. With the help of multiple financing tools to coordinate domestic and international financial business in the supply chain. In the former 5 months of the year 2008, HXB achieved a value of 16.1 billion RMB on enterprise financial business in the supply chain.
SDB (Shenzhen Development Bank)	Developed Supply Chain Finance in Hubei province in 2010, including three series of asset based financial products: Advanced Payment, Inventory and Accounting Receivable.	Multiple in kinds and widely used.

2.2 Rural credit cooperative assisted

In 2009, the rural credit cooperatives in Hubei province advocated to put the leading industries in motion, develop competitive industries and highlight small enterprises' backbone and main channel role in each county's economical development. In order to support technology-advancing, technology-applying, industry-optimizing, environmental energy-saving and region-specializing small

and medium enterprises, Rural Credit Cooperatives developed the mode of “Mortgage + Pledge” and “Guarantee + Mortgage + Pledge”. The logistics financial business mainly includes the logistics financial products follows: Chattel Pledge Loan, Warehouse Receipts Pledge Loan, Liquidity Revolving Loan, Accounts Receivable Pledge Loan, Cooperative Loan and Commercial Property Mortgage-Backed Loan.

2.3 Key cities focused

Some commercial banks in Wuhan developed some logistics financial products or supply chain financial products, such as the “Win-Win Financing Chain” developed by HuaXia Bank and the “Logistics Bank” developed by Guangdong Development Bank. However, these financial products have been rarely applied in the small and medium cities of Hubei province.

2.4 The overall level of development is low

2.4.1 The capability of logistics enterprises to participate logistics finance is limited

Generally, the logistics enterprises in Hubei province are of small size, of limited capability and scattered, they mainly depend on banks to carry out logistics financial business and failed to benefit from logistics finance as its main subject. According to the statistic conducted in Wuhan, there are only 100 or more out of 1200 logistics enterprises have a registered capital over 0.1 million RMB and most of the 1200 are of small scale. Problems like the lack of logistics service diversity, low service efficiency and poor competitive power are found in most of those logistics enterprises. Many of those logistics enterprises are only capable of conducting single stream and segmented logistics service rather than a complete logistics supply chain service. In all, the current situation of Hubei logistics industry is still way behind the development of modern logistics.

2.4.2 Logistics financial business still has not been paid fully attention

The acknowledgment financial institution, logistics enterprises and small-medium enterprises have on logistics finance is quite limited. They are lacking passion on conducting logistics financial business and many of them don't even know that they can solve their financing problems by conducting logistics financial business. Accordingly, the number of banks which conduct logistics business is quite limited and it is joint-equity commercial banks that mainly conduct logistics financial business.

2.4.3 The development of logistics finance is still in the elementary phase.

According to the survey, HuaXia Bank is the only bank which has accomplished some achievements in the area of logistics financial business, many other banks are still in the primary or even lower level when it comes to logistics financial business and most of the banks mixed logistics finance with some general company credit operations without running it according to its own features. Such condition made logistics finance failed to fulfill the enterprises' needs, and made logistics financial business mainly concentrated on limited industries like automobile industry steel industry, etc. Moreover, the logistics financial business conducted within those industries are scattered around without forming a business scale.

2.4.4 The logistics financial products are still underdeveloped and not fully exploited.

Though domestic banks put more emphasis on supply chain financing when they conduct logistics finance, but they are still mainly focused on “inventory financing”; to some extent, this still falls in the category of asset loan. The improvement is that the inventory financing focused logistics financial system allows focal enterprises as the variable of risk control, the supply chain financing mainly concentrates on the middle and lower part of the supply chain and small-medium sized enterprises in the financing market. However, this kind of inventory financing is merely the innovation and scope extending of mortgage and pledge business, rather than thinking about business from the view of the supply chain.

3 Innovative Developments of Logistics Financial Business in Commercial Banks

3.1 Largely improve the development level of logistics finance

Supply chain has been working on its own way to be the mainstream pattern of international industrial organization. Meanwhile, commercial banks developed supply chain management service to seek commercial opportunities. Normally, in a supply chains, numerous small-medium sized enterprises would gather around some focal enterprises which are considered to be the center of the whole supply chain. When banks develop financial business according to the supply chain, it is most of the settlement and financial business the supply chain (including those focal enterprises) that they are trying to conduct rather than trying to serve any single enterprises. It is in this way that commercial banks manage to develop into the focal banks of the whole supply chain. By relying on the trustworthy credit that some

focal enterprises enjoy, supply chain finance gets to drive the capital to places where capital is in need and also gets to support the whole supply chain with capital. In this way, it effectively fulfills the financing needs of some underdeveloped small-medium sized enterprises; optimizes the circulation of capital. Redeemed as the newly development and higher level, supply chain finance creates opportunities for innovation and gradually becomes the area where commercial banks gain their competitive advantages.

According to the industrial policies in Hubei province, logistics and finance are prioritized industries in Hubei province. While Hubei is putting efforts in developing its logistics and being the financial center of central China, the development of modern service industry will certainly be the solid foundation of logistics. With the development of competitive and mainstay industries, multiple supply chains will certainly come into being. Considered this growing trend, commercial banks in Wuhan City Circle should further develop their logistics financial business on the basis of the industrial supply chain.

3.2 Further develop logistics financial business mode

3.2.1 Prepayment-based logistics financial business in the acquisition Phase

Confirming Storage Business (also known as Acceptance Bill Business) is normally described as “bill comes before goods”. In this type of business, client (buyer) can get the acceptance bill from the bank after paying the bank a certain amount of cash deposit. With the acceptance bill, client gets to conduct purchase from the upstream focal enterprise (seller) by paying prepayment in exchange of the bill of lading from the seller. After the purchase, the client will mortgage the bill of lading to the bank and deliver the goods from the bank in batches by paying the bank in batches.

The business mentioned above is suitable for those dealers downstream in the supply chain. In that focal enterprises are in a quite competitive position, dealers downstream are often required to make prepayment in the acquisition phase and will also face big financial pressure by receiving stringent demands from focal enterprises when it comes to price, delivery time, payment period, etc. However, this is the time when the banks using the “future drawn right” role of the prepayment to make a guarantee to finance for dealers. In Wuhan City Circle, the steel industry, automobile industry, non-ferrous metal industry, etc. are suitable in developing such logistics financial business.

3.2.2 Inventory and warehouse receipt based logistics financial business in the production phase

1) Inventory financing is a commercial activity in which enterprise mortgages its chattel to the bank in order to get loans from banks (as shown in figure 1). Meanwhile, in order to realize risk control, enterprise puts its mortgaged chattel under the supervision agencies or third-party logistics enterprises’ supervision. Compared to traditional bank loan, which concentrates on the immovable property, and third-party guarantee, inventory financing transforms enterprises’ chattel (like raw materials and finished products) which banks are not willing to accept into ones that banks are willing to accept. Hence, inventory financing belongs to the chattel mortgage business category. Goods which are of stable value and with good market liquidity like steel, building materials, petroleum, non-ferrous metal, commissariat, cotton, glasses, automobile, paper pulp, fertilizer, rubber, etc.

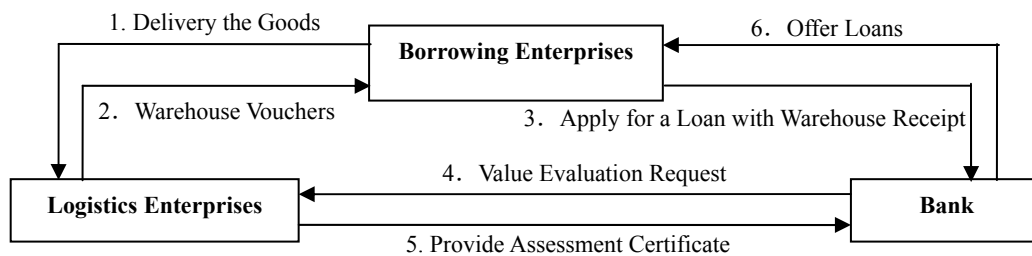

Figure 1 Flow Chart of Inventory Pledge

This type of business is especially suitable for competitive industries in Wuhan City Circle like steel industry, automobile industry, glass industry, commissariat industry, cotton industry, etc. In addition, banks can also conduct this type of business with enterprises which have inventory in both acquisition phase and sales phase of above materials. In this way, enterprises get to vitalize their inventory and solve the financing problems they face.

2) Warehouse receipt financing, usually called as goods goes before bills, in which manufacturing enterprise stores its raw materials purchased or finished products in logistics enterprise’s warehouse as pledge or counter indemnity (as shown in figure 2). In this way, logistics enterprise issues warehouse receipt to the bank which will loan a certain amount of money to manufacturing enterprise under the

warehouse receipt. The logistics enterprise which issues the warehouse receipt gets to supervise the goods in store and the manufacturing enterprise will pay for its loan from the bank in its future manufacturing and sales phases. Because warehouse receipt is based on the Contract of Warehouse Keeping signed between custodian and bailer, it is the certificate of custodian accepting the bailor's goods, so warehouse receipt financing one of rights pledge business.

Generally, suppliers in the upstream of focal enterprise in the supply chain are manufacturing enterprises, they are easy to suffer financing gap. However, the application of warehouse receipt financing can help manufacturing enterprises overcome the financing problems. Commercial banks in Wuhan City Circle can rely on the supply chain in manufacturing industry to develop warehouse receipt financial business.

Figure 2 Flow Chart of Warehouse Receipt Pledge

3.2.3 Account receivable and purchase order based logistics financial business in sales phase

1) In account receivable financial business, enterprise applies for short-term loans from commercial banks by mortgaging its account receivable. However, the loan period is not allowed to exceed the period of its account receivable. When the borrower cannot pay the loan in time, lender bank enjoys the rights to discount, sell its account receivable to get paid with priority.

Account receivable financing mainly occurs in the period from the delivery of goods till the payment made by focal enterprise downstream. The eventual payer is focal enterprise enjoys good capital and credit reputation, which reduces the credit risks bore by the bank and also improve the capital and credit reputation of the borrower. This way of financing is especially suitable for those relatively stable account receivable in the supply chain.

2) Purchase order financing is a way of financing in which enterprise can apply for loans from bank with sales contract and valid purchase order approved by the bank. Small-medium sized suppliers can apply for loans from commercial banks by mortgaging valid sales orders that have covered a certain amount of prepayment and are issued by focal enterprises in the supply chain. To the mortgaged sales orders, banks are supposed to verify the authenticity, risk and value of them with the assistance of logistics enterprises so that banks can authorize an appropriate amount of loan for the applicants. Furthermore, with the assistance of logistics enterprises, banks get to conduct enclosed management on the logistics and capital involved in the acquisition phase and sales phase to make sure that they can get paid back with the payment of goods. In this type of financing mode, enterprises upstream in the supply chain which have received sales orders from focal enterprises get to solve the financing problems to finalize sales orders, so they are quite fit with this type of financing. Commercial banks should develop this type of financial business on the basis of manufacturing industrial supply chain.

3.3 Optimize the development environment of logistics finance in all ways

3.3.1 Enhance governmental support

According to the situation of economy, society and logistics in Wuhan City Circle, it is difficult to achieve the great-leap-forward development of logistics finance by merely depending the current independent development of logistics enterprises and financial institutions. In order to achieve this, our government plays a vital role in publicity and promotion.

3.3.2 Cultivate market entity

Logistics enterprises in Wuhan City Circle are of small size, of great number, scattered around and in disorder. To improve this situation, our government should allocate logistics resources in a reasonable way; should put efforts in cultivating large-scale, all-round logistics enterprises which have solid risk resisting abilities and are capable of leading the development of the whole industry.

3.3.3 Forge elementary platform

Municipal government should set up a financial institution- centered information platform led by government to forge a feedback system of market. First, government should analyze the process of logistics financial technologies and services in comprehensively to achieve scientific classification and

management on information. Secondly, in order to achieve comprehensive processing on information through information communication platform with full smooth and high efficiency, our government should promote the construction of public information platform. Thirdly, our government should establish social credit system to enable financial institutions to keep track of the credit-rating information of logistics enterprises and loan enterprises. In this way, the asymmetry of marketing information and logistics financial risk get to be reduced.

4 Risk Resistances of Logistics Financial Business for Commercial Banks in Wuhan City Circle

Commercial banks are faced with multiple kinds of risks when they conduct logistics financial business: first off, the credits of borrowing venture and supply chain will affect loan recovery directly. It is the credit risks that commercial banks are faced with at the very first. Secondly, parties involved in logistics finance need to sign a contract; each party's rights and obligations are defined on the basis of the contract signed and the laws involved. Hence, commercial banks are faced with legal risks. Furthermore, the value variation and estimation of pledged goods bring commercial banks with market risks. Moreover, the low technical level and the deficiency of operational process also bring operational risks to commercial banks. Therefore, commercial banks which conduct logistics finance should take effective measures to resist and control the above risks.

Firstly, a mechanism of mutual trust and benefits should be established between commercials and third-party logistics enterprises. In logistics financial business, many a risk is due to the asymmetry of information among banks, clients and logistics enterprises. Commercial banks should reasonably establish and develop the information communication platform with logistics and establish the mechanism of mutual trust and benefits. In addition, commercial banks and logistics banks should develop a mechanism of interactive supervision and control; evaluate the credit and the risks of the financing project together to minimize the risks due to the asymmetry of information.

Secondly, commercial banks should reinforce their internal management on business standards and business operation. Logistics enterprises and commercial banks shall set strict business standards and supervisory process in accordance with different modes of logistics financial service, only to minimize the risks due to administrative vulnerabilities and unregulated operations.

Thirdly, commercials banks should establish prompt and efficient feedback system of market information. With this feedback system, commercials banks can gain genuine information of the market to keep in track of the variation on commodity value and sales condition in the market, only to avoid the misestimating result from the asymmetry of information.

Fourthly, commercial banks should establish a mechanism to transfer and share risks. Insurance industry plays a significant role in the benign development of logistics finance; and meanwhile, logistics insurance is the key duty of logistics financial service. By using logistics insurance, the uncertain risks in logistics financial business are transferred into some fixed empirical cost.

5 Conclusions

The coordinated development and innovation of modern service industry are of pivotal importance to the development and adjustment of industries in Wuhan City Circle. With the implement of industrial policies, the industrial clustering and supply chains' come into being in Hubei province, small-medium sized enterprises in Wuhan City Circle will become the vital part of the whole industrial chain. Therefore, the development of logistics financial business not only can create new ways of financing for small-medium sized enterprises, but also can fulfill the financing needs of the industrial chain. In this way, the competitive power of the industry gets to be improved; the coordinated development and innovation of financial service industry, competitive industries and key industries in Wuhan City Circle get to find their own way to prosper. Overall, the conduct of logistics financial business provides commercial banks in Wuhan City Circle with commercial opportunities for their business innovation. The last but not the least, risk resistance and control are of vital significance in the process of conducting logistics financial business for commercial banks.

Research on Financing Mode of Strategic Emerging Industries in the Initial Development Stage

Qi Xiangdong

School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070

(E-mail: diaozf@163.com)

Abstract: In the 21st century, the strategic emerging industry has become the key to economic recovery all over the world. Compared with the traditional industries, strategic emerging industries in the initial development have features such as long cycle investment risks and financing difficulties. This paper presents some suitable financing models for the early developed strategic emerging industries, including direct financing and indirect financing model, and analyses the operation process and the applicability of the financing models.

Key words: Strategic emerging industries; Financing; Development financing

1 Introduction

Strategic emerging industries is a concept proposed in recent years which has no consensus. In this paper, it is defined as the emerging industry which has an important strategic significance on technological innovation, optimization and upgrading of industrial structure and social stability of the coordinated development of the national economy. These industries have features like innovative elements such as knowledge and technology-intensive, long cycle investment risks, the development of international and intense international competition. The seven major industries are considered to be strategic emerging industries including energy conservation and environment protection, new generation of information technology, organisms, high-end equipment manufacturing, new energy, new material and new energy automobile.

This paper does not use the traditional four classification methods (introduction, growth, maturity and decline phases) to classify the industrial cycle. At present, the development stage of strategic emerging industries can not be accurately divided, so we take the concept of strategic emerging industries formally proposed as a starting point, from then on, strategic emerging industries are in the beginning stages of development, namely the initial strategic emerging industries.

In this paper, we think financing mode refers to a complete set of solutions that available and can be reused by the subject of investment when finance for a common characteristic of certain types of financing projects. While the initial financing mode of strategic emerging industries refers to plans available and can be reused for the financing subject when finance on the strategic emerging industry in the early stages of development. Development finance is the combination of single or countries through the establishment of financial institutions with the national credit to provide long-term credit for specific demand. At the same time, with the construction of the market and the improvement of the system, it is a financial form that can accelerate economic development, realize long-term economic growth and other government targets^[2].

2 Target Systems for Financing Mode in Early Industry Based on the Development Finance

The ultimate goal of the establishment of the initial financing mode for the emerging industries based on the strategic development is to reasonable use and fully mobilize the existing financial resources, and modest financial innovation on this basis, so as to promote the transition of strategic emerging industries to the mature stage, and ultimately achieve economic and social sustainable and steady development. To achieve this goal, we need to decompose and clear the target system of the early financing of strategic emerging industries in depth. The process is showed in Figure 1.

3 The Developmental Direct Financing Mode

Development of direct financing mode refers to the developmental financial institutions as a major source of funds in corporate finance, and capital market drive through the direct financial system to support the strategic development of emerging industries. In this process, the developmental financial institutions like commercial banks also play an intermediary role in government-backed credit strengths as a community to raise funds to expand direct investment in total funds. The most essential difference

between development finance and policy finance lies in that development finance implement market action like self-management and self-financing.

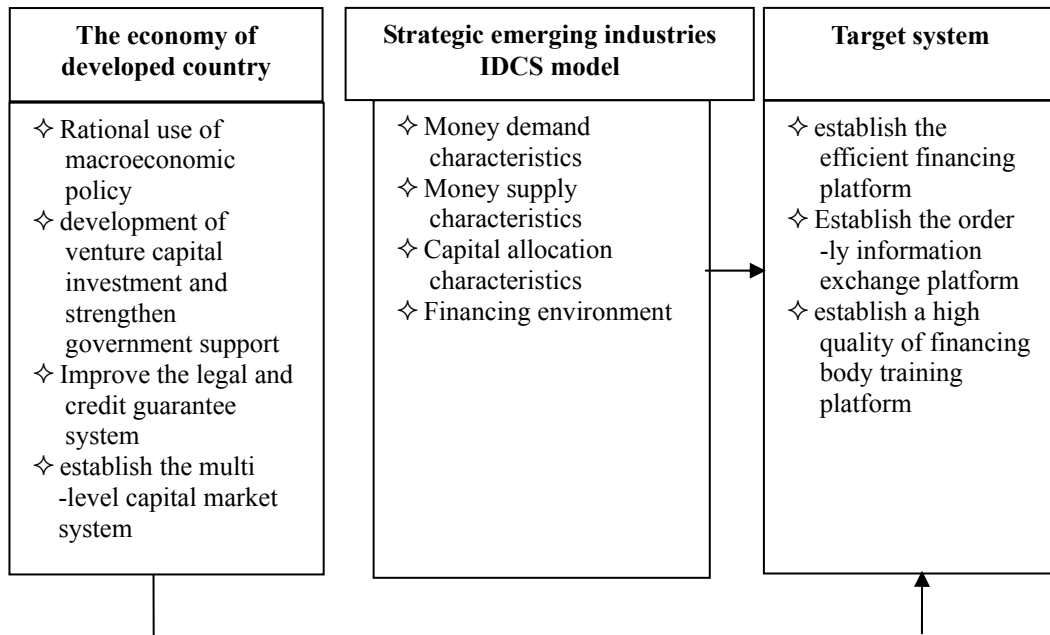

Figure 1 The Ideas of the Construction of the Financing Mode of Target System

Therefore, development finance step into the field of strategic emerging industries financing by direct financial method, actually it is a kind of special means to engage in commercial banking, and its essence lies in the special and commercialization. The speciality of this mode is that it is not a general purpose commercial action purchase of profit, but need to attach some special conditions and special historical mission(Such as improving public welfare,improve the capital markets). The commercialization of this mode refers to its difference to policy in implementation of fiscal policy. Development of direct financing mode is showed in Figure 2.

In the development of direct financing mode, financing activities starts from the government. In accordance with the construction of socio-economic planning, government give clear instructions to developmental financial institutions, and request developmental financial institutions to issue loans. According to the topic studied in this paper, the government needs developmental financial institutions to give necessary financial support to the emerging industries.

For the case of non- specific investment objectives, in receipt of government’s request of funding to support strategic emerging industries loan, there are two kinds of investment options to choose from for developmental financial institutions. One is to select the appropriate corporate to direct invest from the strategic emerging industries. The other is to put money into the capital market, and the capital market to complete the emerging industries of strategic investments. In these two choices, developmental financial institutions actually played the role of venture capitalists^[3]. In this type of investment, in order to pursue their own performance, the developmental financial institutions will make long-term investment and management in companies, which can both accelerate the company's growth rate and the maturity of the industry, but also make accessing to venture capital success that bring high return possible. The second investment program for developmental financial institutions is to invest in the capital market, so as to make non-specific enterprises to integrate into their own funding through the capital market. Compare to the first two programs, such program has higher risk, the reason is the lack of a guarantee provided by the government, at the same time,it use the capital market investments. The various risk in capital markets and corporate commissioned are development finance agency risk institutions must face. However, this solution has its advantages. Capital market has a long history of development in the world, and in China it has developed more than 20 years, and has gradually formed a multi-layer capital market system including the motherboard market, the second board market and the OTC market. Of course, the use of development financial to promote the strategic development of emerging industries is inseparable from the capital markets. But in this program, developmental financial institutions need to pay attention

to select investment projects so as to ensure the risks and benefits of investment projects are reasonable matching. At the same time, we need to pay attention to put investment objectives on the enterprise in emerging industries, and to ensure that government industrial planning objectives are achieved.

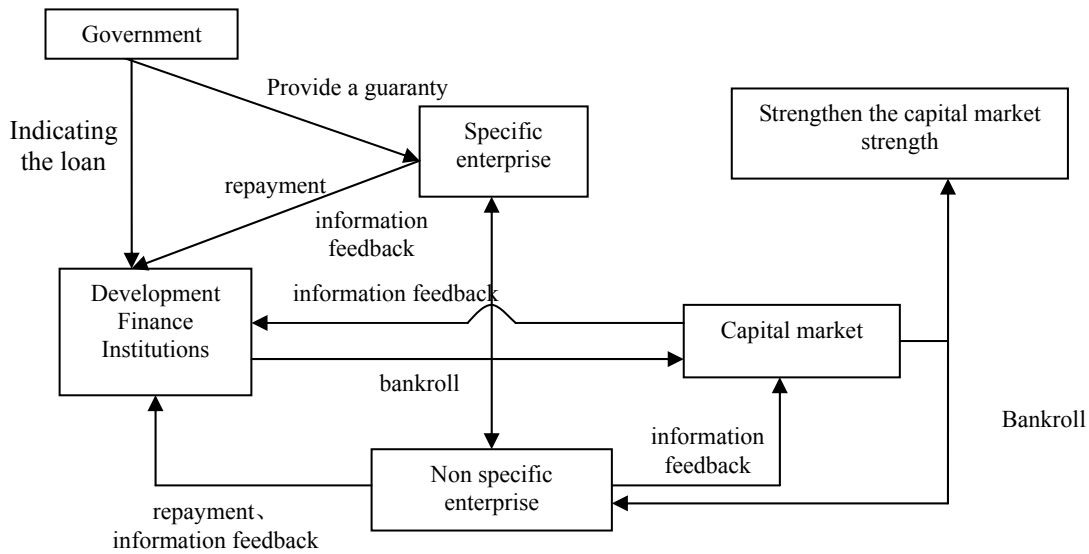

Figure 2 Developmental Mode of Direct Financing

4 The Development Indirect Financing Mode

Developmental indirect financing mode refers to that as a corporate finance non- major source of funding; the developmental financial institutions should support indirect strategic emerging industries through the credit market-oriented financial system. The biggest difference between this financing mode and development direct financing lies in that in developmental financial institutions, provide funding is not the main source of funding of corporate finance, but they participate in social capital investment direction in the forms of equity or loan, so as to expand more financing channels within the corporate in strategic emerging industries. Meanwhile, developmental financial institutions and social capital share the investment risk together and social capital is the main bearer. Developmental indirect financing mode is showed in Figure 3.

Developmental indirect financing mode is the same with direct financing mode in that their source is from the government. In receipt of financial support for loan to strategic emerging industries indication by government, financial institutions who choose the developmental indirect financing mode may choose investment institutions with government-backed or commercial bank-based financial intermediaries to provide fund, and attract social funds into the finance field of strategic emerging industries in the process of investment, and ultimately realize the goal to promote the development of strategic emerging industries by finance.

In the case that developmental financial institutions select institutional investors to invest in strategic emerging industries, in addition to investment institutions with certain government-backed, investment institutions that can be chosen by developmental financial institutions can be cooperate with domestic and foreign venture capital firms and other private capital to cooperate, and then these investment institutions complete the investment business work in the strategic emerging industries^[4].

This mode can stimulate commercial banks to invest in strategic emerging industries for the following reasons: First, government-backed developmental financial institutions is an important shareholder of investment fund, which can pass information that government has decided to vigorously develop strategic emerging industries to commercial banks. Second, due to commercial banks is not the only investment contribution to the strategic emerging industries, investment risk no longer just borne by the banks. Third, it is commercial bank itself who take responsible for the daily operations of the investment fund, so the agency and operational risks for commercial banks is also controllable. To establish the hybrid fund swith commercial banks, the developmental financial institutions can

effectively mobilize commercial banks and social capital to inject capital in strategic emerging industries so as to promote the rapid development of the industry.

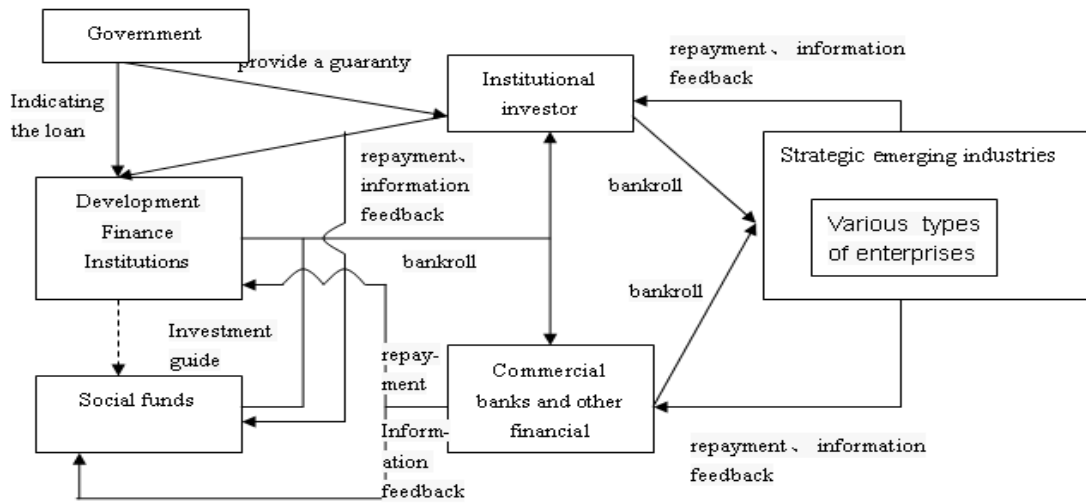

Figure 3 Developmental Indirect Financing Mode

5 Conclusion

The paper shows that developmental finance is a suitable financing mode for strategic emerging industries through mobilizing and using the existing financial resources, and conducting modest financial innovation on this basis, so as to promote strategic emerging industries to the mature stage, and ultimately achieve sustainable economic and social, stable development. In actual operation, we can choose developmental direct financing or developmental indirect financing mode according to the different characteristics of the project.

Comparative Analysis on Characteristics and Countermeasures of China-US Shadow Banking*

Chen Jiyong, Zhen Zhen

Economics and Management School, Wuhan University, Wuhan, P.R. China 430072

(E-mail: cjyhubei@163.com, zhenzhen_abc@126.com)

Abstract: This article studies the composition, size and causes of China's shadow banking, compares the similarities and differences in participants, financial instruments, credit expansion mechanism and the risk characteristics of China-US shadow banking. It can not only help us get deeper understanding of the nature and characteristics of China's shadow banking, but also make a great sense for reflecting financial crisis, preventing systemic risks, exploring financial innovation and strengthening financial supervision on China's shadow banking.

Key words: Shadow banking; Comparative analysis; Risk management; Countermeasures.

1 Introduction

After 2008 U.S. financial crisis, the “Shadow Banking” was known by the public. In recent years, China’s “Shadow Banking” developed rapidly, but due to the huge differences in the economic and financial structure, financial market development stage, and the financial regulatory environment, China's Shadow Banking shows a different way with U.S Shadow Banking in the product structure, mode of operation and risk characteristics.

2 What is “Shadow Banking”

2007, Paul McCulley, worked for Pacific Investment Management Company (PIMCO), first proposed the concept of Shadow Banking, as “the whole alphabet soup of levered up non-bank investment conduits, vehicles, and structures.” Shadow banking is also known as “parallel banking system”, “near-bank”.

Table 1 Introduction of Shadow Banking Definition

People or institution	Perspective	Definition of shadow banking
Paul McCulley	Organization type	the whole alphabet soup of levered up non-bank investment conduits, vehicles, and structures.
Financial Crisis Inquiry Commission(FCIC)	Financing function	The investment banks, most prominently, but also other financial institutions—that freely operated in capital markets beyond the reach of the regulatory apparatus that had been put in place in the wake of the crash of 1929 and the Great Depression.
Financial Stability Board(FSB)	Financing function	Broad definition is credit intermediation involving entities and activities outside the regular banking system. Narrow definition is those types of non-bank credit intermediation that have the potential to pose systemic risks.
Federal Reserve Bank of New York	Financing function	Shadow banks are financial intermediaries that conduct maturity, credit, and liquidity transformation without explicit access to central bank liquidity or public sector credit guarantees.
Ben Bernanke	Organization type	Shadow banking refers to the intermediation of credit through a collection of institutions, instruments, and markets that lie at least partly outside of the traditional banking system.
International Monetary Fund(IMF)	Financing function	"Near-bank entities" typically intermediate credit (or hold securities of those loans) traditionally originated by banks, primarily rely on capital market financing, have not generally been eligible for regular central bank funding (though access has been expanding), and in some cases are only loosely regulated. They include the special

* This paper is supported by the National Social Science Foundation of China “China participating in global economic rebalancing strategy and path in post-crisis period”(Grant NO. 11& ZD008).

		purpose entities that issue ABS, mortgage-backed securities (MBS), CDOs, and asset-backed commercial paper (ABCP), and firms such as real estate investment trusts, global funds, the GSEs, and, until recently, the five major U.S. investment banks.
Paul Tucker	Financing function	Instruments, structures, firms or markets which, alone or in combination, replicate, to a greater or lesser degree, the core features of commercial banks: monetary or liquidity services, maturity mismatch and leverage.
China Banking Regulatory Commission(CBRC)	Organization type	Pursuit to FSB's definition, the non-bank financial institutions under CBRC supervision do not belong to the scope of shadow banking. Because the regulatory system for six non-bank financial institutions is complete, they should not be included in the scope of shadow banking, including trust companies, finance companies, auto finance companies, financial leasing companies, money brokers, consumer finance companies and other non-bank financial institutions.

From the perspective of regulatory arbitrage, due to the different regulatory requirements between non-bank financial institutions and banking institutions, the size of banking institutions, balance-sheet and off-balance sheet business, the driving factor of regulatory arbitrage for shadow banking always exist. From a regulatory perspective, the shadow banking is not necessarily visible institutions, nor can completely rule out the traditional commercial banks.

3 The Composition, Size And Causes of China's Shadow Banking

3.1 The composition of China's shadow banking

In recent years, the loans of China's banking sector accounted for the total amount of social financing decreased rapidly from 91.9% in 2002 to 52.1% in 2012. It reflected the development of direct financing channels and deepening of financial markets. But, we cannot ignore that a large number of financing needs converted to shadow banking business, and the nature of its credit facilities have not changed.

Figure 1 The Proportion of Bank Loans Accounted for Total Social Financing Amount

Source: WIND, website of the People's Bank of China

At present, China regulatory agencies, financial institutions and scholars dispute on the definition and the scope of China's shadow banking. This article agrees with financial institutions' and scholars' opinions and focus on financing functions of the shadow banking, considering the credit intermediation and the financial instruments outside the traditional banking business as the shadow banking. Participants of the shadow banking mainly involves three categories: one is the bank, the second is the non-bank financial institutions with the ability of credit creation, including securities institutions, trust companies, finance companies, security companies, small loan companies, the third category is private financing institutions, including pawn shops, private lending, internet finance.

Table 2 The Business and Products of China's Shadow Banking

Participant	Banks' off-balance sheet business	Banks' other off-balance sheet business		Trust financing			Asset Management of Brokers	Other non-bank financial institutions and private financing
	Off-balance financial product	Entrusted Loan	Off-balance sheet commercial bills	Cooperation of bank and trust	Cooperation of government and trust	Cooperation of real estate company and trust	Cooperation of bank and brokers	small loan companies, pawn shops, private lending, internet finance
Product	financial product	Entrusted Loan	Discounting, acceptance	Single trust product, beneficiary right	Infrastructure trust, funds pool trust	Single trust product	Targeted asset management plan	Lending

3.2 The size of China's shadow banking

According to FSB's Global Shadow Banking Monitoring Report 2012, the total size of the global shadow banking was about \$ 26 trillion in 2002, and then increased to \$ 62 trillion in 2007, with the average annual growth rate up to 48%. The global scale slightly declined in 2008, but then gradually rebounded, increased to \$ 67 trillion in 2011. The amount of U.S. shadow banking was largest, approximately \$ 23 trillion in 2011; the amount of Euro zone was after the United States, about \$ 22 trillion; the size of British about \$ 9 trillion; the amount of China's shadow banking accounted for about 1% of global size, about 4 trillion RMB, with an average annual growth rate of 110% post-crisis, ranking first in the world.

At end-2005

At end-2011

Figure 2 Share of Assets of Non-Bank Financial Intermediaries
(Source: FSB, Global Shadow Banking Monitoring Report 2012)

Domestic and foreign research institutions generally believe that size of China's shadow banking is huge. Standard & Poor's estimated that, by the end of 2012, China's shadow banking was 22.9 trillion RMB (about 3.7 trillion U.S. dollars), equivalent to 34% of total banking sector loans and 44% of gross domestic product (GDP) at the same year. China merchants securities(CMS), China investment securities(CIS), CITIC securities(CITIC), China securities CO, Haitong securities estimated China's shadow banking was 23 to 29 trillion RMB, higher than the estimation of Standard & Poor's from 0.4% to 26%. The statistical results of FSB and other agencies are quite different, mostly because that the data of FSB derived from China Banking Regulatory Commission, whose statistical standard of shadow banking is relatively strict and small.

Table 3 Estimation of China's Shadow Banking Size (Billion Yuan)

Institution	FSB	Standard & Poor	China merchants securities	China investment securities	CITIC securities	China securities Co.	Haitong securities
size	4	22.9	28.25	26.6	23 - 25	24 - 26	28.8

Note: The estimated time points of S & P and FSB were the end of 2012 and 2011, and the estimated time points of remaining institutions were the end of 2012 Q3.

3.3 The causes of China's shadow banking

Monopoly and regulation. Those factor lead to the high price and low level of money supply, including the entry barrier to traditional banking system, industry scale effect and strict regulatory requirements. Interest rate controls lead to excess money supplies and unsatisfied social funding needs bypass the formal banking system by innovating products and channels. Different financial regulatory systems obviously influence the development of the shadow banking. Because of separate regulatory systems, industrial monopolies, entry barriers and spread controls in China, the size of the shadow banking is very great.

Regulatory arbitrage. Different regulatory measures regarding for financial institutions and financial assets result that, in one hand, commercial banks and non-bank financial institutions (trust, securities companies) established various "channels" to seek regulatory arbitrage, and on the other hand, commercial banks converted asset categories for improving capital utilization efficiency and performance rewards by financial products, i.e. commercial bills and repo.

The imbalance of money supply and demand. On the money demand side, the commercial banks need to control credit risk, and tend to choose the companies, projects and individuals with higher ratings, more collaterals or stronger guarantee ability. In Chinese economy, there are a higher proportion of unqualified borrowers, e.g. many small enterprises and individuals cannot reach financial terms of bank loans and collateral requirements, real estate and government financing platform cannot get new loans from the banks directly due to regulatory prohibitions. On the money supply side, the attractiveness of deposits was greatly weakened for investors by the interest rate controls. A lot of money escaped from banks' balance sheets to seek better investment opportunities, and be attracted by various types of financial products with higher yields and lower risk.

Financial innovation. Financial innovations constantly dig and meet various demands of money suppliers. For example, MBS and ABS which meet the housing needs, CDS against bond defaults, all has the same characteristics of acquiring yields from duration spreads, liquidity spreads, credit spreads and leverage.

Technological innovation. The advances of information and network technology, as the representative of large data, cloud computing, mobile Internet, greatly expand the scope of time and space for financial transactions. Investors can borrow and lend money at any time and any place by internet. In recent years, China emerged internet-based financing models, including Ali small loans, P2P finance, and public finance and so on.

4 Comparative Analysis of China-US Shadow Banking Risk Characteristics

4.1 Comparative analysis of China-US shadow banking

From the participating subjects, the U.S. shadow banking is constituted by non-bank financial institutions, including investment banks, hedge funds, money market funds, bond insurance companies, structured investment vehicles (SIVs), etc. U.S. shadow banking system steps across the protection for traditional commercial banks, and competes with banks, rather than cooperation. China's commercial banks dominated in the agencies, scale, and channels. So, China's shadow banking is mainly led by commercial banks. The relationships of other financial institutions with banking are more cooperation than competition, mainly as a channel cooperation to avoid banking supervision.

U.S. shadow banking was established on derivatives, securitization and re-securitization of financial instruments, including mortgage-backed securitization (MBS), asset-backed securitization (ABS), asset-backed commercial papers (ABCP), structured investment vehicles (SIVs), collateralized debt obligation (CDO) and credit default swap (CDS) and other diversified financial products. Through complex financial operations based on classification, cutting, credit enhancement, re-packaging, these financing products create financial market liquidity and gradually replace commercial bank credit market, or achieve self-creation relying on bank credit. China's shadow banking mainly consists of financial products of bank-trust cooperation and bank-securities cooperation, private financing to meet the financing needs of SMEs and personal credit business. The complexity and innovation of financial products of China's shadow banking are far less than that of U.S.

From the credit expansion mechanism, the U.S. shadow banking was mainly based on derivatives, securitization and re-securitization of financial instruments, formed a bottom-up "chain" credit intermediation systems including the product lines, the business departments and the agencies. The

credit creation of U.S. shadow banking was built on monetary banking credit, through securitization, eventually expanded credit creation functions of the entire financial system. The main target of U.S. shadow banking is to service the virtual economy. By the end of 2007, the average leverage ratio of top ten U.S. investment bank's was 30.6 times, greatly improved comparing with that of 23 times in 2003. China's shadow banking is relatively simple credit expansion mechanism with low leverage, services the real economy in a certain extent, which differs from the U.S. shadow banking.

4.2 Comparative Analysis of China-US shadow banking risk characteristics

This article compared the risk characteristics of China-US shadow banking, and preliminary assessed the risk severity (Table 4). U.S. shadow banking has a high level of risk in leverage, maturity mismatch, credit mismatch, liquidity mismatch and systemic risk. The reason is that the U.S. shadow banking is the product of well-developed financial market. China's shadow banking is product of underdeveloped financial market, unsatisfied financial needs and regulatory arbitrage. China's shadow banking has a high level of risk in systemic risk because it highly was associated with bank's customers, channels and products.

Table 4 The Shadow Banking Risk Characteristics and the Risk Severity

Risk characteristics	Description	Risk severity	
		U.S.	China
Relationship with traditional banking	The shadow banking system associated extensive, not only closely related to each other, but also associated with commercial banks and private investors, closely dependent on banks and their holding companies to participate, formed a complex chain of credit intermediation.	High	Very high
Leverage	The leverage of shadow banking can be greatly improved, without capital, reserves and leverage limitation,	Very high	Low
Maturity mismatch	Through short term borrowing and long term lending, the shadow banking can obtain high profits term spreads. When Term Structure of Interest Rates of financial market will fail, causing panic even deleveraging liquidity crisis.	Very high	High
Credit mismatch	Shadow banking provides credit enhancement services to acquire credit spreads benefits, or finance high credit asset to low credit asset to arbitrage.	Very high	High
Liquidity mismatch	Shadow banking lacks stable source of deposit, finances highly liquid assets from financial markets, counterparties and investors, invest objects are generally illiquid high-yield projects. There is a liquidity mismatch. Market liquidity depletion will lead to the funds chain of shadow banking breaks.	Very high	High
Imperfect regulation	To some extent, the shadow banking has the traditional banking functions, but without or less regulation of prudential standards or procedures. The shadow banking need not to disclosure the capital adequacy ratio, leverage ratio, liquidity and other information, nor regular supervision with the primary rely on self-discipline.	High	High
Systematic risk	Shadow banking is more fragile and vulnerable to a liquidity crisis, has a close relationship with channels, customers, products, transactions of traditional banking system. Their risk will be substantially transmitted to the banking system.	Very high	High
Incomplete risk control system	Shadow banking is not included in the deposit insurance system, the mechanism of central bank discounting and the last lender protection. Generally, the government guarantees does not apply on the shadow banking system.	High	High

5 Conclusions

China's shadow banking rapidly expanded, closely associated with traditional banks, and the systemic risk is high, but the complexity of the product, the leverage ratio of it is less than that of U.S. shadow banking. In post-crisis era, China should improve the regulatory mechanism, and guide the China's shadow banking to develop healthy and reasonably.

Regulatory authorities need to innovate the idea of financial regulatory and make the clear definition of China's shadow banking, preventing the excessive expansion of shadow banking and regulatory blind spots.

In the macro-prudential perspective, China should build up across-agency collaboration regulatory mechanisms which consider the monetary and fiscal policies, and the regulatory requirements for the banks, securities, insurances, trusts and other non-bank financial institutions. It will expose the shadow banking to the sun and promote the further development of China's financial markets.

The shadow banking business involves commercial banks, trusts, securities, private finance, and other participants. The key point is to prevent the risk contagion in the financial market, and distinguish the risk responsibilities among the participants in shadow banking system.

Commercial banks should improve the risk management mechanism for "internal" shadow banking, establish an effective means of risk identification, evaluate the direct and indirect risks of the shadow banking, establish risk prevention and response mechanisms, strengthen the management of cooperation agencies, explicit exit mechanism for business, and build up risk stop-loss and self-help mechanisms.

Regulate private financing development, gradually combines induction of the regulatory approach and mandatory legal system to promote China's financial industry stability and development.

(E-mail: 17552939@qq.com, athen2003@163.com)

Abstract: This paper conducts empirical analysis on exchange rate pass-through to import and export prices in China with monthly data from 1999 to 2008, and finds that exchange rate pass-through is higher to export prices than to import prices. The analysis shows that the difference in the pass-through of exchange rate to import and export prices arises from the difference in industrial margin, international treaties and trade barrier. Based on empirical results and China's sustained trade surplus, this paper concludes that the demand elasticity of China's export is small due to strong competitive edges in price of China's export products, so the appreciation of RMB will do little in reducing China's foreign trade surplus.

Key words: Exchange rate passes through; Import price; Export prices

1 Introduction

Over the years, China's trade surplus continues to expand and foreign exchange reserves increase substantially, which have imposed great pressure on China's economic development and policy making. Meanwhile, China's great trade surplus has been always condemned by America and EU and they point out that it is because RMB is undervalued that China's export increases greatly and vast trade deficit occurs in their own countries. So since 2002, RMB has been faced constant appreciation pressure that the international community exerted. In 2005, China initiated the reform about the exchange rate formation mechanism of RMB and since then RMB has been put on the track of appreciation. So far, the exchange rate of RMB against USD has risen about 20%. The subprime crisis took place in 2007 in the United States brings about serious economic recession in most countries especially in USA and Europe, these countries point out that the substantial trade surplus of China is harmful for them to recover the economy growth and employment, so the United States and other countries force China to appreciate RMB again in 2010.

Theoretically, fluctuation of exchange rate does affect one country's import and export following two steps. At first, the fluctuation of exchange rate affects the prices of import and export, which then affect the volume of import and export and trade balance further. In order to know exactly whether exchange rate fluctuation affects China's import and export and whether the appreciation of RMB reduces China's vast trade surplus or not, it is important to understand the effects the exchange rate change leads to at two steps. This paper tries to analyze the first step at which exchange rate change affects the import and export, that is to say, the paper tried to investigate to what extent the exchange rate fluctuation of RMB affects the prices of China's import and export. The research is of great significance to understand the exact effects of the exchange rate change of RMB on China's foreign trade and then is helpful for adopting appropriate foreign exchange rate and trade policies.

The structure of this paper is as follows, part I is the introduction and part II is literature review, part III is the procedure and results of empirical analysis, and the last part is the conclusion and suggestion.

2 Literature Review

The effects of exchange rate change on import and export prices can be theoretically interpreted by the Law of One Price (LOP) and Purchasing Power Parity (PPP). If the LOP holds, the change of exchange rate will be passed through to the prices of import and export in the same proportion, and the change of price will affect the import and export further. So the more the exchange rate appreciates, the more the trade surplus can be affected.

Though there have been much literature study exchange rate pass-through of RMB in China, most of them are focused on the pass-through to import or export price exclusively. This paper will analyze and compare the exchange rate pass-through of RMB both to import and to export prices, thus is more

helpful for understanding the overall effect of the exchange rate change on foreign trade and for adopting concrete import and export policies. We analyze the exchange rate pass-through empirically with monthly data from 1999 to 2008, and adopt the methods of co integration test and impulse response analysis.

3 Empirical Analyses

3.1 Model and data

According to LOP, the import price is decided by the exporting price abroad and the exchange rate of local currency, which can be expressed as follows:

$$IMP = E \times FP \quad (1)$$

Where IMP stands for domestic import prices; E is the exchange rate of local currency (direct quotation); FP is the price of the imported goods in foreign currency. Taking it into consideration that income level will influence the demand for import and further raise prices, this paper adds income level (Y) as one of the factors that affect prices of import. Taking logarithm of values on both sides of Expression (1) and we get the liner equation for logarithm of import prices as follows:

$$\ln IMP = \ln E + \ln FP + \ln Y \quad (2)$$

Similarly, the liner equation for logarithm of export prices is as follows:

$$\ln XP = \ln E + \ln DP + \ln FY \quad (3)$$

Where XP stands for domestic export price; E is the exchange rate, DP stands for domestic price of the exported goods, FY is income level in foreign countries.

According to Expression (2) and (3), we establish the econometric model for import and export prices as follows:

$$\begin{aligned} \ln IMP &= a_0 + a_1 \ln E + a_2 \ln FP + a_3 \ln Y + \varepsilon_0 \\ \ln XP &= \beta_0 + \beta_1 \ln E + \beta_2 \ln DP + \beta_3 \ln FY + \varepsilon_1 \end{aligned} \quad (4)$$

Based on Expression (4), this paper uses monthly data from 1999 to 2008 to analyze the exchange rate pass-through to China's import and export prices empirically. IMP and XP are expressed by the import and export price indices respectively. The exchange rate E is expressed by nominal effective exchange rate of RMB. Foreign price FP is expressed by price index of foreign producers, while domestic price DP is expressed by the domestic producer price index (PPI). Domestic income level Y and foreign income level FY are expressed by domestic GDP and foreign GDP respectively.

Since there is no monthly data for domestic GDP, this paper converts the seasonal data for domestic GDP into monthly data using Eviews 6.0. And there is no global GDP data, we convert seasonal GDP data of China's major trade partners (USA, Russia, South Korea, Japan and some countries in EU) into monthly data first and then made seasonal adjustment with X12. Afterwards, GDP of those countries are converted into dollar-dominated GDP using monthly exchange rate of those countries' currencies against USD, and then the monthly global dollar-dominated GDP are obtained by summing up monthly dollar-dominated GDP of those countries. Foreign producer price index FP was calculated using producer price index of China's major trade partners (Japan, USA, Russia, South Korea and EU), it is the weighted average number of those countries' PPI and the weight is obtained by each country's share in China's import volume.

Except that RMB nominal effective exchange rate comes from the website of the Bank for International Settlements, other data involved are derived from the database of China Economic Information network. For the domestic PPI, import price index and export price index, we take data in 2005 as 100. Foreign GDP and domestic GDP were also converted into relative data by taking data in 2005 as 100. The analysis software used in this paper is Eviews6.0.

3.2 Unit root test

For time series, stability of all variables shall be tested before doing regression analysis in order to avoid spurious regression. This paper uses ADF criteria to test the stability of variables in Expression (4) and the results are shown in Table 1.

According to Table 1, the series including $\ln IMP$, $\ln E$, $\ln FP$, $\ln CGDP$, $\ln XP$, $\ln PPI$ and $\ln GDP$ are unstable at 5% significance level, but their 1st difference series are stable, which indicates that all the variables are I(1) series.

Table 1 Results of ADF Test

Variables	Methods	Lag intervals	5% critical value	ADF value	Results
lnIMP	Trend	3	-3.44902	-3.04052	Unstable
dlnIMP	Intercept	2	-2.886509	-3.25138	Stable
lnE	Trend	1	-3.448348	-0.85634	Unstable
dlnE	Trend	0	-3.448348	-8.03321	Stable
lnFP	Trend	1	-3.448348	-2.18935	Unstable
dlnFP	Trend	0	-3.448348	-5.7532	Stable
lnY	Trend	11	-3.451959	0.315966	Unstable
dlnY	Trend	12	-3.452764	-5.72806	Stable
lnXP	Trend	1	-3.448348	-1.38985	Unstable
dlnXP	Trend	0	-3.448348	-21.095	Stable
lnDP	Intercept	0	2.885863	-1.21527	Unstable
DlnDP	Trend	0	-3.448348	-8.80182	Stable
lnFY	Trend	0	-3.448348	-1.91652	Unstable
DlnFY	Trend	0	-3.448348	-8.81863	Stable

3.3 Cointegration test

According to unit root test, the seven variables were all 1st order integration and cointegration test was conducted for Expression (4) to check whether there existed a long-term cointegration relationship between those variables. Since import prices model and export prices model involve four variables, it is inappropriate to use two-step stability test (this method is suitable to examine the relationship between two variables) and this paper adopted Johansen method to conduct cointegration test for variables.

The optimal lag intervals of VAR model for import prices was 4 according to AIC and SC rules, therefore the lag intervals in co integration test was 3. The results of co integration test were as shown in Tab.2.

Table 2 Results of Co Integration Test for Import Prices Equation

Null hypothesis	Trace Statistic	Critical Value 5%	Maximum Eigen value	Critical value of maximum Eigen value 5%
no	64.75843	54.07904	39.62574	28.58808
One at most*	25.13269	35.19275	11.19731	22.29962
Two at most	13.93538	20.26184	8.571199	15.8921
Three a most	5.364184	9.164546	5.364184	9.164546

Trace test and the maximum eigenvalue test indicated that a cointegration equation existed between import prices, RMB nominal effective exchange rate, foreign product prices and domestic income at 5% significance level and the normalized long-term cointegration equation is as follows:

$$LNIMP = -0.1730 LNE -1.1354 LNFP + 0.6772 LNCGDP +7.4379 \quad (5)$$

(0.25907) (0.42028) (0.11094) (1.82314)

The optimal lag intervals of VAR model for export prices was 2 according to AIC and SC rules, therefore the lag intervals in cointegration test was 1. The results of cointegration test were as shown in Tab.3.

Table 3 Results of Cointegration Test for Export Prices Equation

Null hypothesis	Trace Statistic	Critical Value 5%	Maximum eigenvalue	Critical Value of maximum Eigenvalue 5%
no	67.2315	54.07904	32.26359	28.58808
One at most*	34.96791	35.19275	21.84329	22.29962
Two at most	13.12462	20.26184	10.79431	15.8921
Three a most	2.330314	9.164546	2.330314	9.164546

Trace test and the maximum eigenvalue test indicated that a cointegration equation existed between export prices, RMB nominal effective exchange rate, domestic product prices and foreign income at 5% significance level and the normalized long-term cointegration equation is as follows:

$$\text{LNXP} = 0.7593\text{LNE} + 0.7453 \text{LNPP} + 0.0905\text{LNGDP} - 2.7969 \quad (6)$$

(0.26827) (0.32136) (0.24291) (1.48210)

From the above two cointegration equations, the elasticity of import prices against exchange rate was -0.173, that is to say, import prices decline by 0.173 percentages as RMB nominal effective exchange rate rises by 1 percentage. The elasticity of export prices against exchange rate was 0.759, that is to say, export prices rises by 0.759 percentages as RMB nominal effective exchange rate rises by 1 percentage. This is consistent with the theoretical analysis that import prices decline and export prices rise when domestic currency appreciates. This also means that rise of RMB exchange rate has expected pass-through into import and export prices and this will cause China's import to increase and export to decrease. On one hand, the long-standing problem of vast trade surplus in China can be narrowed; on the other hand, China's export products and employment will be affected adversely.

In addition, a distinctive feature can be seen from the analysis results that RMB exchange rate has different pass-through into import and export prices and latter is greater. The t-statistic was 0.6678 in import prices equation, while the t-statistic was 2.830 in export prices equation, thus the significance level of the latter was apparently higher than the former. The author thought there were several reasons:

Foreign exporters are more capable to adjust product prices according to exchange rate fluctuation. Imported products of China are mainly hi-tech products, energy (oil), raw materials (iron and steel) fuels and non-ferrous metal and those industries are highly profitable. For example, oil is basically a monopolized industry and has little competition, so different prices can be set in different markets. Because a stabilized supply of resources products is quite important to China's construction and development, many manufacturers have built a long-term supply relationship with international resources suppliers and effects of exchange rate on import prices of those products are weakened^[5]. Export products of China are mostly agricultural products, manufactured products and textiles and those industries have fierce competition and low profitability. Therefore, when RMB exchange rate changes adversely, foreign exporters adjust profitability or raise price makeup to counteract loss in exchange rate fluctuation, but domestic exporters can make limited adjustment. Besides, export cost is higher than import cost in China. Since China's export products usually have price advantage, many countries restrict price and quantity of China's export products. During recent years, they limit China's export products to enter markets of their own countries and set trade barrier in the name of green trade. In opposite, imported products of China usually have high technological content or scarce resources and cannot be replaced by domestic products. Therefore, China has set few trade barriers for imported products. As is known to all, trade barrier will increase trade cost and lower trade cost can bring more profit for foreign exporters, thus their pricing strategies are not so incentive to exchange rate.

4 Conclusions and Suggestions

This paper made use of monthly data from 1999 to 2008 and studied RMB exchange rate pass-through effect on China's import and export prices through cointegration test, vector error correction model and impulse response analysis, and the research findings are as follows. 1. In a long run, RMB exchange rate fluctuation has negative pass-through effect on import prices but positive pass-through effects on export prices, which is consistent with theoretical analysis. Besides, the elasticity of import prices against exchange rate (absolute value) is only 0.173, much lower than the elasticity of export prices against exchange rate at 0.759. This indicates the impact of exchange rate on export prices is much greater than that on import prices. In addition, this research also shows that import prices are in inverse proportion to foreign product prices and direct proportion to domestic income, while export prices vary directly with domestic product prices and foreign income. 2. There is a reverse amendment mechanism in exchange rate pass-through effects on both import and export prices, but both import and export prices are slow to recover to the long-term equilibrium. When exchange rate suffers from a positive impact, import prices will show negative response which lasts for a long time and export prices will show positive response which is weak and lasts for a short period.

According to results of empirical researches, RMB nominal effective exchange rate has exerted pass-through effect on both import and export prices which are consistent with theoretical expectation. To put it clearly, appreciation of RMB causes export prices to rise and import price to decline. In particular, the degree of pass-through effects on export prices reaches 0.76. This means, the changes of

RMB effective exchange rate have significant effects on China' import and export commodity prices, especially on export product prices. Therefore, RMB exchange rate can play a crucial role in China's import and export. This can explain why America and other countries have been imposing pressure on appreciation of RMB in face of China's vast trade surplus, in the expectation of reducing price competitiveness of China' export products and lowering down China's export volume through substantial appreciation of RMB. This can also explain why Chinese government has always been holding a cautious attitude towards appreciation of RMB, and placing great emphasis on initiative and controllability in adjustment of RMB exchange rate. Since exchange rate pass-through effect on import prices is much lower than that on export prices, appreciation of RMB may have no major impact on import but great adverse effects on export.

Appreciation of RMB exchange rate causes import prices to decrease and export prices to rise, but the low price of China's export products leads to small elasticity of export demand and thereby safeguards China's export. However, it is not a permanent solution to maintain export and promote economic development by relying on our advantage in low-priced products. What lies behind lower prices is cutthroat competition among Chinese exporters and massive consumption of China's resources and cheap labor. Besides, low-price competition leads to low margin of China's export industry, which is unfavorable to the long-term development of our export industry.

Abstract: In order to make the analysis of information ability and core competence in Chinese state-owned joint stock banks, structural equation model (SEM) is used in this paper. By factor choice, research supposition, factor decomposition, model establishment, data collection and reliability analysis and validity testing, the SEM can effectively conduct empirical research on information ability and core competence in Chinese state-owned joint stock banks. For illustration, the collected copies are 429, and the effective rate of collection is 42.9%, which has satisfied the requirement that the questionnaire returns-ratio is not lower than 20% in the data investigation. The empirical results show that Information productivity ability has the remarkable incentive function to the risk control ability, product development ability and internal control ability. Furthermore, the product development ability have obtained a more effective cultivation, risk control and internal control ability have obtained the certain cultivation. Finally, the practical data examination can provide the feasible theory reference for the state-owned joint stock commercial banks (SJSCBs) to develop information ability and cultivate core competence.

Key words: Chinese state-owned joint stock commercial bank; Information ability; Core competence; Structural equation model (SEM)

1 Introduction

The competition among the modern enterprises is essentially a fight for the core competence. The cultivation of core competence is the basic strategy for enterprises to maintain the sustainable competitive advantage. Similarly, being one kind of typical knowledge industry, the competition in banking industry mainly depends on a race for core competence. The massive resources have been put into the following aspects such as product development, risk control and market marketing to rapidly cultivate the partial superiority in some domains so as to construct the core competence. Therefore, the cultivation of core competence has been considered to the most important strategy for banks' development in the state-owned joint stock commercial banks (SJSCBs) since last century.

The core competence theory stemmed from the early-1990s. In 1990, Prahalad & Hamel firstly proposed the concept of core competence. He thought that the core competence was the cumulative knowledge in the organization, which was specially related to how to coordinate the different productive skills and make the organic synthesis of the technological means. The prologue to the theoretical probe was opened^[1]. So the organization can acquire the core competence through the cultivation and the development in the long time.

Being the constituent part of the enterprise strategic theory, the core competence theory was the fifth stage of strategic theory. Therefore, the core competence theory stemmed from an insufficiency of the traditional strategy theory^[2]. The core competence theory believed that enterprise competition went far beyond the scope of Porter Five Force Model so that the theory was a mixture of the internal and external factors in enterprises.

The concept of bank information ability stemmed from the concept of enterprise information ability. At National Commission on Libraries and Information Science (NCLIS) in 1974, Paul Zurkowski, the President of Information Industry Association (IIA) put forward the concept of information ability for the first time. The information ability referred to the skill and the technology through which the person with information ability took advantage of the multiple message tools and the main information resource to deal with problems^[3]. Therefore, the bank information ability referred to a series of information

* This work was supported by NSF (No.70773001) and Bid Project "Xinjiang SME Internal Control Issues". The project was from Humanities and Social Sciences Key Research Base in Xinjiang Normal University-Enterprise Development Research Center of Xinjiang.

management activities completed by staffs with the certain information ability with the help of information tool in order to finish some information tasks.

In fact, the insufficiency of information ability has been restricting the enhancement of core competence variously in the SJSCBs. The insufficiency of information ability will restrict the SJSCBs-related innovation ability in the domain of risk management, reduce the SJSCBs-related risk value assessment ability, and hinder the application of quantitative technique in risk management^[4].

Therefore, based on the cultivation goal of the core competence, the analysis on the incentive mechanism of information ability has promulgated the incentive microscopic mechanism of the SJSCBs information ability, which will provide the theoretical reference for strengthening the development, the management and the application of the information ability and promoting the growth of core competence in the SJSCBs.

2 The Establishment of Research Model

2.1 The choice of research factors

2.1.1 The factor choice of information ability system

American information scientist Marchand proposed the information orientation (IO) theory. The information application efficiency included three key factors such as the information behavior and the value, the information management practice, the information technology practice^[5]. The US management scientist John Mckean believed the enterprise information ability system included the following essential factors such as staffs' application information ability, the information valid disposition, the organizational structure, the reward of the effective information application from various functional departments, the information culture of manifesting the information value, the full understanding of information function and the leadership skill in relation to supporting information investment, the enhancement of the information value as well as the accuracy of information of the applied technology information^[6]. The enterprise information ability was divided into five essential factors and bank information ability included three aspects. According to the above analysis, the SJSCBs information ability can be divided into three essential factors in the research such as information productivity ability, information retrieval ability and information application ability.

2.1.2 The factor choice of core competence system

The SJSCBs core competence system can be divided into the following four essential factors including risk control ability, product development ability, internal control ability and market development ability. Risk control ability is related to operational risks, credit risks and market risk. Product development ability refers to the design ability, the transformation ability and combination ability of each kind of financial product. Internal control ability refers to the promotion ability of each kind of internal control essential factor. Market development ability refers to the development ability, the optimization ability and the coordinated ability towards marketing channel.

2.2 Research supposition

2.2.1 The incentive analysis of information productivity ability towards core competence

The information productivity ability is the basic element of information ability because the bank can gather the massive information resource and make the cultivation of the core competence only through the information productivity ability. The following research suppositions are given:

H1A: SJSCBs information productivity ability promotes the implementation effect on the risk control ability.

H1B: SJSCBs information productivity ability promotes the implementation effect on the product development ability.

H1C: SJSCBs information productivity ability promotes the implementation effect on the internal control ability.

H1D: SJSCBs information productivity ability promotes the implementation effect on the market development ability.

2.2.2 The incentive analysis of information retrieval ability towards core competence

The information retrieval ability is the crucial factor concerning information ability because only after completing the demand information search, the information-related application value can be achieved. The information retrieval ability is the link of information collection ability and the information application ability. According to the above analysis, the following research supposition can be seen.

H2A: SJSCBs information retrieval ability can promote the implementation effect on the risk

control ability.

H2B: SJSCBs information retrieval ability can promote the implementation effect on the product development ability.

H2C: SJSCBs information retrieval ability can promote the implementation effect on the internal control ability.

H2D: SJSCBs information retrieval ability can promote the implementation effect on the market development ability.

2.2.3 The incentive analysis of the information application ability towards the core competence

Being the fundamental essential factor in the information ability system, the information application ability is the combination of information resource and the banking process, which will has the most direct motivation function to the cultivation of the core competence. In the SJSCBs, the risk control, the product development, the internal control and the market development need the support of the massive reliable information. But the information-related support behavior towards these leading services is a gradual process and a process of gradual integration. Therefore, the cultivation of the information application ability is a kind of management art, which will be affected by kinds of factors such as staff's business proficiency, incentive mechanism, banks' strategy development project and enterprise culture and so on. According to the above analysis, the following research suppositions are presented.

H3A: SJSCBs information application ability promotes the implementation effect on the risk control ability.

H3B: SJSCBs information application ability promotes the implementation effect on the product development ability.

H3C: SJSCBs information application ability promotes the implementation effect on the internal control ability.

H3D: SJSCBs information application ability promotes the implementation effect on the market development ability.

2.3 The essential factor decomposition

2.3.1 The essential factor analysis of information ability

According to the literature, combined with the operational mechanism of the SJSCBs information ability system, the essential factor analysis of the SJSCBs information ability system can be achieved.

Information productivity ability can be divided into four measure targets such as the information gathering ability (X1), the information storage ability (X2), the combination ability (X3) and the information filter ability (X4).

Information retrieval ability can be divided into four measure targets such as the database ability(X5), the infrastructure performance (X6), the software ability (X7) and the professional cultivation (X8).

Information application ability can be divided into four measure targets such as the market application ability(X9), the product application ability (X10), the flow transformation ability (X11) and the policy-making application ability (X12).

2.3.2 The essential factor analysis of core competence

According to the literature, combined with the operational mechanism of the SJSCBs information ability system, the essential factor decomposition of the SJSCBs core competence system can be achieved.

Risk control ability can be divided into four measure targets such as the credit risk control ability (Y1), the operational risk control ability (Y2), the market risk control ability (Y3) and the comprehensive risk control ability (Y4).

Product development ability can be divided into four measure targets such as the core product development (Y5), the basic product development (Y6), the augmented product development (Y7) and the latent product development (Y8).

Internal control ability can be divided into four measure targets such as the climate control (Y9), the risk loss assessment (Y10), the implementation of internal control system (Y11) and the information feedback mechanism (Y12).

Market development ability can be divided into four measure targets such as the market segmentation ability (Y13), the product positioning ability (Y14), the network marketing ability (Y15) and the customer value analysis (Y16).

2.4 The establishment of research model

The research plans to use the structural equation model (SEM) to examine the theoretical supposition. Suppose that the information productivity ability is ξ_1 , the information retrieval ability is ξ_2 ,

the information application ability is ξ_3 , simultaneously suppose that the risk control ability is η_1 , the product development ability is η_2 , the internal control ability is η_3 , and the market development ability is η_4 . According to the research supposition, the research model is shown in Figure 1.

Figure 1 Research Model

3 Model Checking

3.1 Data collection

The research used Li Kete 7 meters to carry on perform towards 28 measure targets. The sample units were the bank municipal branch of Chinese SJSCBs system. The data investigation provided 1000 questionnaire, the collected copies were 429, and the effective rate of collection was 42.9%, which had satisfied the requirement that the questionnaire returns-ratio was not lower than 20% in the data investigation. 168 samples with the better data quality were selected among the recycling questionnaire. The ratio of the sample number and the target number was 6:1, which had satisfied the examination requirement of the SEM data. Among them, there were 60 copies of samples to China ICBC, 29 copies of samples to China Construction Bank, 36 copies of samples to Agriculture Bank of China, 43 copies of samples to Bank of China. So these samples had represented the overall sample characteristics of Chinese SJSCBs. The data interviewee mainly was the senior management, the head of department or backbone in banks. Therefore, the data quality had the high credibility. The data investigations began in March 19, 2012, end in April 30, 2012, altogether lasted for 41 days.

3.2 Reliability analysis and validity testing

In banks' information ability system scales, Cronbach α value was 0.7548. The first-level confirmation analysis result of banks' information ability system was GFI=0.932, CFI=0.917, TLI=0.955, RMR=0.014, RMSEA=0.038, Cronbach α =58.128, $p=0.000$ in the bank information ability system, the factor load of each measure target was bigger than 0.5, and the smallest T value was 2.331. Therefore, the bank information ability system had the good reliability and the validity.

Table 1 Effect Matrix

Assumption	Extraneous source variable	Endogenous variable	Path assumption	Load coefficient	Standard error(se)	T value
H1A	Information productivity ability	Risk control ability	$\xi_1 \rightarrow \eta_1$	0.30	0.09	3.23
H1B	Information productivity ability	Product development ability	$\xi_1 \rightarrow \eta_2$	0.32	0.10	3.20
H1C	Information productivity ability	Internal control ability	$\xi_1 \rightarrow \eta_3$	0.45	0.13	3.46
H1D	Information productivity ability	Market development ability	$\xi_1 \rightarrow \eta_4$	0.13	0.08	1.52
H2A	Information retrieval ability	Risk control ability	$\xi_2 \rightarrow \eta_1$	0.12	0.07	1.76
H3A	Information application ability	Risk control ability	$\xi_3 \rightarrow \eta_1$	0.35	0.08	4.38

The Cronbach α value of the banks' core competence system was 0.7643. The first-level confirmation analysis result of the bank core competence system was GFI=0.980, CFI=0.921, TLI=0.912, RMR=0.030, RMSEA=0.043, Cronbach α =132.52, $p=0.000$, the factor load of each measure target was bigger than 0.5, and the smallest T value was 2.223. Therefore, the bank core competence system had the good reliability and the validity.

The research used LISREL 8.7 to perform the whole model test. The effect matrix (r) of the extraneous source variable and the endogenous variable was shown in Table 1.

Simultaneously the whole model fitting index was shown in Table 2.

Table 2 Fitting Index Tabulation

Fit index	X ² /d.f.	RMSEA	RMR	CFI	NFI	IFI	CFI	TLI
Index current value	1.354	0.034	0.065	0.988	0.927	0.909	0.945	0.929
optimal value trends	<3	<0.08	<0.1	>0.9	>0.9	>0.9	>0.9	>0.9

Therefore, the model's fitting effect was good so that model revision did not need to be corrected.

4 Conclusions

According to the fitting index tabulation, the model fitting effect is good. Therefore, the check result of effect matrix tabulation has the certain reliability, which can effectively reflect the intrinsic relevance between SJSCBs information ability and the core competence.

According to the effect matrix tabulation, based on the cultivation goal of the core competence in SJSCBs, the microscopic function mechanism of information ability is followed. Information productivity ability has the remarkable incentive function to the risk control ability, product development ability and internal control ability, but lacks the effective incentive to the market development ability. Information retrieval ability has the remarkable incentive function to the product development ability, internal control ability and market development ability, but lacks the effective incentive to the risk control ability. Information application ability has the remarkable incentive function to the risk control and product development ability, but lacks the effective incentive to the internal control ability and the market development.

Therefore, SJSCBs information ability has the certain incentive function to the formation of core competence, but this kind of incentive function still has certain deficiencies, which needs to expand and perfect continuously. From the information ability angle of view, the information productivity ability and information retrieval ability have the better incentive function to the formation of core competence, but the information application ability is weak. At the same time, based on the formation of core competence, under the operational mechanism of information ability, the product development ability have obtained a more effective cultivation, risk control and internal control ability have obtained the certain cultivation, but the cultivation effect of market development ability is weakest.

Based on the practical data examination of the information ability and the core competence in SJSCBs, the research conclusion has the higher objectivity, which will provide the feasible theory reference for the SJSCBs to develop information ability and cultivate core competence with a clear aim.

Abstract: Comprehensive transport planning, comprehensive and systematic, is aimed for the optimal benefits of the entire system which includes railways, highways, waterways, civil aviation, pipeline and other transport subsystems. This paper deals with the selection of the optimal comprehensive transport planning program among several candidates through the use of quantitative evaluation, constructing a comprehensive evaluation index system and also evaluation models, elaborating on the principles of quantitative evaluation, clarifying the significance of quantitative evaluation.

Key words: Transportation engineering; Comprehensive transportation planning; Design scheme; Quantitative evaluation

1 Introduction

Since the various transport subsystems complement, influence and compete with each other, it is inadvisable to be solely concerned about the efficiency of a particular mode of transport while devising a comprehensive transport scheme (System Theory suggests that local optimum is no guarantee of global optimum). Therefore, comprehensive transport planning is fairly complex, being multi-level, multi-factor and multi-target. The implementation of the scheme will not only improve the transportation network itself, but also exert great influence on society, economy, and environment. Moreover, evaluation of a comprehensive transport scheme hinges not only on its feasibility but its impact upon technology, economy, society, environment, etc.

2 The principles of Quantitative Evaluation and the Evaluation Index System

2.1 The principles of quantitative evaluation

Systematic evaluation forms the basis of systematic decision-making, which means that without proper evaluation, correct decisions can no be made. The evaluation of the comprehensive transport scheme can help to locate its demerits and discern the weak points of the modern comprehensive transport system, which is conducive to effective policy-making and betterment of the modern comprehensive transport system. In view of all that have been discussed above, the basic principle and ultimate goal of evaluation of the comprehensive transport planning is to select the optimal scheme from a variety of candidates by means of quantitative analysis, or to revise the existing scheme and to redesign on the basis of evaluative analysis, hence providing scientific support for the ultimate decision-making.

2.2 The establishment of an evaluation index system

Considering the structural characteristics and attributes of the modern comprehensive transport system, this paper sets up a hierarchical, multi-indicator index system based on the principles of systematicity, measurability, stratifiability, comparability. The index system is composed of four categories of indicators: technical, economic, social, environmental; it is stratified into three layers: the target, namely the comprehensive evaluation that constitutes the ultimate goal, the criteria that involves all the factors influencing the realization of goals, the specific indexes.

Table 1 The Modern Comprehensive Transport Planning Evaluation Index System

Target	First-level indexes (criteria)	Indexes
Comprehensive Transport Planning Program O	Technology-A	The proportion of comprehensive transport hub nodes-A1
		The convenience of a comprehensive transport network(reach ability)-A2
		Comprehensive transport network connectivity-A3
		Continuity of the comprehensive transport network-A4

	Economy-B	The direct economic benefit of the national economy-B1
		Operating divisions economic benefits -B2
		Indirect economic benefits of the national economy-B3
	Society-C	Consistency with national policies and local economic development-C1
		Land development and utilization-C2
		Employment-C3
		Rational distribution of population-C4
		National defense and foreign exchange-C5
		Exchanges and national unity -C6
		People's lives (User benefits, transport and delivery) -C7
	Environment-D	Land possession-D1
		Pollution (discharge of pollutants, noise) -D2
		The ecological balance-D3
The natural landscape and cultural relics-D4		

2.2.1 Technical evaluation of the comprehensive transport planning program

The technical evaluation of the comprehensive transport planning program means analyzing the internal structures and functions of the comprehensive transport system from a technical point of view, aiming at checking the rationality of the scheme and providing technical support for optimization and decision-making. The four indicators above are the main technical indicators used to describe a comprehensive transport network, according to the widely adopted methods in planning. While the four indicators are put into practical use, it is unnecessary to calculate each and every one of them; rather, in specific situations, certain indicators should be highlighted and singled out for calculation, analysis and evaluation.

2.2.2 Economic evaluation of the comprehensive transport planning program

Generally, the national economic evaluation model is employed in the evaluation of the economic benefits of the comprehensive transport planning program, which entails two dimensions: costs and benefits. In accordance with the principle of rational distribution of resources, national economic evaluation adopts evaluation indexes such as shadow price etc. to calculate the social resources consumed in the project and the social devotion drawn from the project, aiming at measuring aims at measuring the economic rationality of projects. National economic evaluation mainly involves calculating the national economic benefits and costs, calculating and selecting the shadow price, calculating the national economic indexes as well as comparing economic schemes. National economic evaluation is widely used in the field of railways, highways and other transportation projects, as well as a large water hydropower projects, the state-controlled strategic resource development projects.

2.2.3 Social evaluation of the comprehensive transport planning program

Social evaluation means analyzing the social influences of the comprehensive transport scheme (project) within the planning area. As is known to all, transportation plays an essential role in urbanization, exploitation of resources, employment expansion, and economic prosperity of a region. For example, Port of Shanghai has profoundly accelerated the development of Shanghai. It is not presumptuous to say that transportation is irreplaceable and unchallenged in terms of its profound influence on society and economy. However, it is usually difficult to quantify fits social influences and different situations may lead to widely different results. Therefore, it is advisable to combine quantitative and qualitative analysis in carrying out social evaluation, while taking the specific circumstances into account.

2.2.4 Environmental evaluation of the comprehensive transport planning program

The environmental impact of the transportation projects includes air, water, soil and noise pollution, harm to animals and plants, damage to natural landscapes and cultural relics, etc. The environmental evaluation index can be regarded a salute to the "low-carbon transportation, pollution-free transportation" appeal. At the annual meeting of the 2010 World Economic Forum New Champions, Premier Wen Jiabao said in his speech that China will make great efforts to build a low-carbon-emission

transportation system, to boost the demonstration and industrialization of low -carbon technology research, to enhance the ability to cope with climate change, to actively carry out international cooperation to address climate change under the principle of “common but differentiated responsibilities”. It should be noted that the first three first-level indicators are positive, whereas the environmental evaluation indicators are negative, namely only “minimal impact on the ecology” scores the highest marks and proves to be optimal. Thus in statistical analysis, reverse scoring helps to achieve the consistency of outcomes.

3 The Comprehensive Evaluation Model of the Comprehensive Transport Planning Program

In the process of a comprehensive evaluation of the comprehensive transport plan, the analytic hierarchy process is not suitable for comparing various transport plans yet suitable for calculating the weight value of each level, whereas the fuzzy evaluation method is quite the reverse. In light of the respective merits and demerits of the analytic hierarchy process and fuzzy evaluation, as well as the characteristics of the comprehensive transport planning program, this paper adopts and combines the two methods to construct an evaluation model. There are four steps to implement the model, namely data normalization, using AHP to determine the weight of each level, using fuzzy evaluation to evaluate the plan and establish a fuzzy relation matrix, and finally drawing conclusions. Having tested and demonstrated the model, two comprehensive transport schemes m and n are picked out for empirical evaluation and analysis, so as to get the final results of the evaluation.

3.1 Data normalization

While using the formula to calculate the composite indicator, some important indicators may make up a very small proportion of it due to its small value, which results in the distortion of the comprehensive index value. The main reason for that is the differential meaning and units of each indicator. Therefore, data normalization is prerequisite for a comprehensive evaluation. The formula is as follows:

$$Y_i = \frac{X_i - X_{\min}}{X_{\max} - X_{\min}} \tag{1}$$

In which , X_i is the secondary index value, X_{\min} is the minimum value of the secondary index, whereas X_{\max} is the maximum value of the secondary index, Thus, the outcome Y_i belongs to the interval [0, 1].

3.2 Using AHP to determine the weight of indicators

(1) The implementation of AHP

①calculating the product of the elements of each row of the matrix M_i

$$M_i = \prod_{j=1}^n a_{ij} (i = 1, 2, \dots, n) \tag{2}$$

②Calculating the nth root \bar{W}_i

$$\bar{W}_i = \sqrt[n]{M_i} \tag{3}$$

③ Normalizing vector quantities $\bar{W} = [\bar{W}_1, \bar{W}_2, \dots, \bar{W}_n]^T$

$$W_i = \frac{\bar{W}_i}{\sum_{j=1}^n \bar{W}_j} \tag{4}$$

Thus, $W = [W_1, W_2, \dots, W_n]^T$ is the desired eigenvector.

④Calculating the minimum eigenvalue of the matrix O- λ_{\max}

$$\lambda_{\max} = \sum_{i=1}^n \frac{(AW)_i}{nW_i} \tag{5}$$

In which

$$AW = \begin{pmatrix} \frac{W_1}{W_1} & \dots & \frac{W_1}{W_n} \\ \frac{W_1}{W_1} & \dots & \frac{W_1}{W_n} \\ \vdots & \ddots & \vdots \\ \frac{W_n}{W_1} & \dots & \frac{W_n}{W_n} \end{pmatrix} \begin{pmatrix} W_1 \\ W_2 \\ \dots \\ W_n \end{pmatrix} = \begin{pmatrix} nW_1 \\ nW_2 \\ \dots \\ nW_n \end{pmatrix} = nW \tag{6}$$

$(AW)_i$ Means the i the element (indicator)of the vector quantity AW.

(2) Determining the weights of indicators

Using the comprehensive evaluation of the plan as the criterion, experts establish a judgment matrix O for sub indexes according to pair wise comparison methods and Method of nine marks.

Table 2 Weight Values of First-Level Indicators

Evaluation of the comprehensive transport planning program O	Technology-A	Economy -B	Society-C	Environment-D
Technology-A	1	2	1/3	1/4
Economy-B	1/2	1	1/2	1/3
Society-C	3	4	1	1/2
Environment-D	1/2	3	4	1
Weights	0.1358	0.1142	0.2797	0.4704

Notes: $\lambda_{max}=4.1532$, $CI=0.0511$, $RI=0.9$, $CR=0.0569$

Therefore, the outcomes are as follows: $\lambda_{max}=4.1532$; $CI=0.0511$; $RI=0.9$; then $CR = \frac{CI}{RI} = \frac{0.0511}{0.9} = 0.0569 < 0.10$.

Analysis of factors of the criteria level generates the weight coefficient of each index, which can be arranged in the order of importance: Technology-A (0.1358), Economy-B (0.1142), Society-C (0.2797), Environment-D (0.4704) .

Although the analytic hierarchy process can also produce a comprehensive evaluation result through pair wise comparison of the sub-criteria layer in light of the main criteria layer, it is not suitable for comparing various indicators, which can be made up by fuzzy evaluation. Therefore, weights of the first-level indicators can be evaluated by means of fuzzy evaluation and the fuzzy matrix.

3.3 Calculating the composite score

The composite score is calculated by the weighted average according to the index weighs and ratings.

3.4 Comparing, selecting and determining the planning program

Arrange the plans according to their composite scores and then select the optimal one. The calculation model is:

$$D = \sum_{i=1}^n (k_i \cdot P_i)$$

D ——the composite score; k_i ——the weight of the i -th index; P_i ——the score of the i -th index; n ——the total number of indexes.

4 Conclusions

Undoubtedly, there are various factors influencing the selection of the optimal comprehensive transport planning program. In this paper, however, a lot of emphasis is put on “resource-saving and environmental friendly “indicators, thus some evaluation outcomes may not be in complete consistency with the actual situation. But it is not presumptuous to say that the mathematic evaluation models adopted in this paper may prove to be very useful support tools for government policy-making. Nevertheless, in actual situations, while analyzing and comparing the various comprehensive transport planning programs on the basis of evaluation models, it is essential that the actual situations and study objects be taken into consideration in order to ultimately make the right decisions.

Abstract: This paper compared the comparison of advanced manufacture industry between Wuhan and the five national central cities in China from the GDP, total industrial output value and key industries, and pointed out the current problems of Wuhan in developing advanced manufacture industry, including unchanged industrial system model, weak industrial competitiveness, imperfect technological innovation system and unreasonable spatial layout. Besides, it suggested Wuhan to focus on electronic information industry, automobile industry, equipment manufacturing industry, steel industry, petrochemical industry, food processing industry and bio-pharmaceutical industry, and optimize its industrial layout.

Key words: Advanced manufacture industry; Wuhan; Five national central cities; Industrial layout

1 Introduction

In 1992, the concept of advanced manufacturing industry was first formally proposed by the U.S. government. In their opinion, the advanced manufacturing industry is the industry with advanced manufacturing technologies. In China, the advanced manufacturing industry is a new formulation appeared in official documents in recent years. It is a summary of industrial clusters which lead the direction of industrial manufacturing development and master the advanced technologies. Under the background of informatization and globalization, it means that the manufacturing industry constantly absorbs high-tech achievements from the aspects of electronic information, computers, machinery, materials, modern management techniques, etc. And these advanced manufacturing technologies will be integrated and applied into the entire process of design, manufacturing, online testing, marketing services and management, thus to realize the production of informatization, automation, intelligence, flexibility and greening and acquire both good economic and social effects.

The national central cities in China refer to the cities that are on the top of the national urban system. For external, they play an important role in developing export-oriented economy and promoting international cultural communication. They are the centers of finance, trade, culture and management of Asia and even the whole world. For internal, they own the functions of lead, radiation and distribution, which can be seen in politics, economy and culture. In February 2010, the *national urban system planning*, released by the Ministry of Housing and Urban-Rural of China, put forward five national central cities and six regional central cities. The former are Beijing, Chongqing, Tianjin, Shanghai and Guangzhou, while latter are Shenyang, Nanjing, Wuhan, Shenzhen, Chengdu and Xi'an. So Wuhan should actively seek its difference with the five national central cities and try to get closer to them.

2 Comparisons and Analysis

Wuhan is an important industrial base in China and has a complete range of industries. There are 33 industry categories and more than 30,000 manufacturing companies, including steel, automotive, optical communications, machinery, petrochemicals, bio-pharmaceuticals, textiles, clothing, food, etc. Its comprehensive industry strength is the first in central and western China.

In recent years, the modern industrial system in Wuhan has been an important means of stimulating economic growth. First, its heavy industry sectors have taken shape initially. So far, Wuhan has basically formed four pillar industry sectors and six competitive industries. The former contains steel, automobiles and machinery, optoelectronics information and petrochemical, while the latter includes environmental protection, tobacco and food, household appliances, textile and apparel, pharmaceuticals, paper and packaging printing. Second, its key industrial clusters grow fast. According to Hubei Provincial Government, its key industrial clusters are laser industry cluster in East Lake High-tech Zone, food processing industry cluster in Dongxihu District, Xugu mushroom industry cluster in Xinzhou

* This paper is supported by the Wuhan City Circle Manufacturing Development Research Centre.

District, Jiahai apparel industry cluster in Huangpi District, electronics industry cluster in Caidian District and packaging printing industry cluster in Hannan District. Third, the spatial layout of manufacturing industry has basically formed five industry segments. They are Qingshan sector (Qingshan-Yangluo), Economic Development Zone sector (Zhuankou Development Zone-Hanyang-Caidian), High-Tech Zone sector (East Lake High-tech Zone-Hongshan-Jiangxia), Dongxihu sector and Hanzheng Street sector (Qiaokou-Jiangnan-Dongxihu). Fourth, fifteen industry-chains with comparative advantages have appeared, including steel and deep processing, automobiles and parts, consumer electronics, bridges and steel, petroleum and chemical industry, modern communications, semiconductors, machinery and equipment, transportation equipment, clean energy and new materials, food and tobacco, pharmaceuticals, household appliances, textile and apparel, and paper printing and packaging.

2.1 GDP

With the implementation of the rising strategy of central China and the construction of two-oriented society, Wuhan focuses on the industrial strategy, promotes the transformation of old industrial bases, accelerates the construction of advanced manufacturing, and has basically built modern industrial system which can adapt to the features of central cities. However, the advanced manufacturing in Wuhan is still less-developed than the national five central cities in China. Table 1 is a comparison of GDP in 2008-2012 between Wuhan and the national five central cities in China.

Table 1 GDP in 2008-2012 unit: hundred million

City	2008	2009	2010	2011	2012
Beijing	11115	11865.9	14113.6	16000.40	17801
Tianjin	6719.01	7500.8	9224.46	11307.28	12746.4
Shanghai	14069.87	14900.93	17165.98	19195.69	20101.33
Guangzhou	8287	9112.76	10748	12303.12	13551.21
Chongqing	5793.66	6528.72	7925.58	10011.13	11459.00
Wuhan	4115.51	4620.86	5565.93	6762.2	8004.58

From Table 1, the GDP ranking of five national central cities in China is Shanghai, Beijing, Guangzhou, Tianjin and Chongqing. Wuhan's GDP is rather less, which indicates that its economic level and economic power is far from the five national central cities.

2.2 Total industrial output value

The data of the total industrial output value in 2008-2012 can be seen from Table 2. There is also a distance between Wuhan and the five national central cities in China.

Table 2 Total Industrial Output Value in 2008-2012 unit: hundred million

City	2008	2009	2010	2011	2012
Beijing	10413.09	11039.13	13699.84	14513.63	15405.7755
Tianjin	12503.25	13083.63	16751.82	20862.74	23250.54
Shanghai	25120.92	24091.26	30114.41	32445.15	31548.41
Guangzhou	12639.05	12502.08	15329.21	16718.30	18640.9
Chongqing	5755.90	6772.90	9143.55	11847.06	13104.02
Wuhan	6251.79	6317.94	7004.96	8461.21	

Unlike the GDP, the rank of the total industrial output value is Shanghai, Tianjin, Guangzhou, Beijing and Chongqing. Shanghai is still the first and Chongqing is still the last. But the ranking of Beijing has dropped, which is caused by the larger proportion of tertiary industry in Beijing's industrial structure. No matter how the rank of the national central cities changes, the total industrial output value of Wuhan is still behind them. To develop Wuhan's advanced manufacture industry, its volume and speed should both be improved.

2.3 Key industries

It cannot be denied that Wuhan's industry has achieved a relatively higher growth during the 11th Five-Year Plan. It formed six billion-industry clusters which includes electronic information, automobile, equipment manufacturing, iron and steel, petrochemical and food. And in high-tech industry, the annual growth rate of output value was more than 23%.

In Table 3, there is a comparison of the key industries of advanced manufacturing between Wuhan and the five national central cities in China. It is obvious that the electronic information industry, automobile industry and equipment manufacturing industry are the priority development industries for the five national central cities, as well as Wuhan advanced manufacture industry. Besides, each city has its own key industries which are different from the others. These special key industries are developed according to their local conditions.

Table 3 Key Industries

City	Key industries	
Beijing		Petrochemical new materials, pharmaceutical industry, metropolitan industries, bio-industry
Tianjin	Electronic information industry, automobile industry, equipment manufacturing industry	Aerospace industry, petrochemical industry, bioengineering and pharmaceutical industry, new energy and new materials industry, light and textile Industry, defence science technology
Shanghai		Petrochemical and fine chemical industry, fine steel manufacturing, complete sets of equipment manufacturing industry, biomedical manufacturing
Guangzhou		Electronics product manufacturing industry, petroleum and chemical industry, shipbuilding industry, complete sets of equipment, technical equipment and extreme manufacturing, fine steel manufacturing
Chongqing		Automobile motorcycle industry, chemical engineering industry, material industry,
Wuhan		Iron and steel industry, petrochemical industry, bioengineering and pharmaceutical industry

3 Current Problems

Compared with the five national central cities in China, Wuhan's current problems in developing advanced manufacture industry can be found.

3.1 Unchanged industrial system model

The industrial system model in Wuhan has not been essentially changed. Wuhan's advanced manufacture industry still regards the traditional industries and the traditional growth pattern as the mainstay, which causes a considerable distance from the new-type industrialization. At present, the characteristic of heavy industrialization in Wuhan is distinctive. Since there is no fundamental change in its growth pattern, the heavy industrialization makes the economic growth over-rely on the capital investment, resource and energy consumption and environmental damage, which turns out to be high input, high consumption, high pollution and low output.

3.2 Weak industrial competitiveness

The industrial efficiency of Wuhan is low. The per capita GDP in Wuhan is quite inferior to the five national central cities in China. This is because Wuhan's industries focus more on traditional industries, which are low value-added, labor-intensive and have shorter industrial chain.

3.3 Imperfect technological innovation system

Wuhan is full of rich scientific and educational resources and innovative talents, as well as a number of national key laboratories, enterprises' research centers, etc. However, its technological innovation system which is market-oriented and regards enterprises as the mainstay has not been established yet. So the conversion rate of scientific achievements and industrialization is low. The government and enterprises' investments of independent innovation capacity have obvious gaps compared with the five national central cities in, either the absolute volume or the percentage of GDP.

3.4 Unreasonable spatial layout

The manufacturing enterprises' core competitiveness is not strong, and the spatial layout needs further adjustments. The scale level of industrial development is low. The industry concentration and market share are not enough. These result in weak core competitiveness of both industry and enterprises. In the perspective of spatial layout, some less environmentally friendly manufacturing enterprises are still left in Wuhan's central urban area, such as chemicals, textiles, locomotives, machinery, etc. They negatively affect the upgrade of the central urban areas' overall function.

4 Future Key Industries in Wuhan

Based on the above shortcomings, the advanced manufacturing in Wuhan should accelerate the pace of technological innovation and combine new industries and traditional industries to make pillar industries bigger and stronger and promote the construction of national advanced manufacturing center.

4.1 Electronic information industry

The optical communications, consumer electronics, high-end devices, integrated devices, and integrated circuits should be stressed. Electronic information industry should treat the construction of "Wuhan • Optics Valley of China" as the key point and strengthen the leadership of two dominant industries, namely photonics and mobile, and continue to promote the development of high-end optoelectronic and accelerate the upgrades of mobile communication equipment.

4.2 Automobile industry

Automobile industry is the largest pillar industry in Wuhan and has a certain capacity of self-development and innovation. It should concentrate on improving vehicle production scale, speeding up the development of automotive parts and service system, and improving the supporting capacity of the industry chain. In practical terms, the automobile industry should actively support Dongfeng Motor Corporation. Relying on the Dongfeng Automobile Company, the industry can take efforts to improve its production scale and comprehensive strength of passenger vehicles, actively develop energy-saving and new energy vehicles, greatly support innovation and cultivate independent brands, expedite parts and industrial services system development, and accelerate the building of automobile and parts export bases, thus making Wuhan become the first-class cluster base of automotive industry.

4.3 Equipment manufacturing industry

The equipment manufacturing industry should focus on shipping and supporting, locomotives, electrical equipment, numerical control machine and metallurgy equipment, so as to build an international standard shipbuilding and repair base and the largest research and development manufacturing base of railway in China.

4.4 Steel industry

The steel industry should concentrate on the steel deep processing to build a national high-quality steel production base for rolled silicon steel sheet, automotive sheet steel, high-performance constructional steel and so on. Wuhan Iron and Steel Group is the core enterprise of the steel industry in Wuhan. The development of the steel industry can depend on the Group and extend its industrial chain. The upstream should develop design and manufacturing of metallurgical equipment, while the downstream can create a steel deep processing base in China.

4.5 Petrochemical industry

This industry should rely on the key enterprises and focus on high value-added petrochemical industry, salt chemical and fine chemical products. Besides, the industry should extend its industrial chain of deep processing on new materials and chemical to build an oil and chemical industry production base in the central China.

4.6 Food processing industry

The food processing industry can work on beer, soft drinks, vegetable oil, dairy products, meat and poultry processing, condiments, convenience foods and other food processing industries, and support the major projects, in order to promote food processing enterprises become bigger and well-known.

4.7 Bio-pharmaceutical industry

In China, Wuhan is in the leading position of antiviral drugs, steroids, antipyretic analgesics and anesthetics. Relying on the key enterprises, like biological products research institute, Wuhan can utilize its unique resource advantages and technological advantages. And to build an important domestic pharmaceutical industry base, Wuhan should accelerate the development of diagnostic reagents and vaccines and modern medicine.

As to the other competitive industries, for example, textile and apparel industry should focus on high-grade knitted underwear and fashion leisure clothing. Light home appliances industry should focus on air conditioners, freezers, water heaters, kitchen utensils, small appliances, etc. Building materials industry should focus on the new wall materials, green decoration materials, inorganic non-metallic materials, etc.

5 Layout Optimization

With the development of the industrial system, the spatial layout of Wuhan industry has clear and positive changes and shows a new layout. The changes are mainly in two aspects. For one thing, the traditional manufacturing industry has speeded up the pace of relocation. The manufacturing industry has significantly gathered in the Third-Ring and Fourth-Ring, which forms an industrial belt around the city. For another thing, the level of area gathering is improving and five industry-gathering areas are being built. They are steel-chemical industry and environmental protection industry cluster (Qingshan-

Yangluo-ZuoLing), automobile and electromechanical industry cluster (Wuhan economic and technological development zone-Hanyang-Caidian-Hannan), photoelectron and biological medicine industry cluster (East lake new technology development zone-Hongshan-Jiangxia), food industry cluster(Dongxihu-Huang Jinkou) and urban industry clusters(Qiaokou-Jianghan-Dongxihu).

In the future, the industrial layout of Wuhan should be further optimized. Besides promoting the above industrial layout process, the layout should also be combined with the function of central city and “8 +1” city circle development strategy, which means the implementation of the "four circles" strategy. They are the urban industry circle based on downtown within the Third Ring, the core industry circle between the Third Ring and The Outer Ring, the industrial circle made up of six distant suburban area and the industrial docking circle of “8 +1” city circle.

6 Conclusion

Among the five national central cities in China, the development of the advanced manufacture industry in Shanghai is the fastest, while Chongqing is the least developed. However, compared with the five national central cities in China, the advanced manufacture industry in Wuhan still has a long way to go both in quantity and quality. At present, the weak points of Wuhan during its development are the unchanged industrial system model, weak industrial competitiveness, imperfect technological innovation system and unreasonable spatial layout. They are the obstacles which prevent the improvement of the advanced manufacture industry in Wuhan.

Thus, to reach the standard of national central city in China, Wuhan should reposition its key industries and optimize its layout. The former means Wuhan should focus on the electronic information industry, automobile industry, equipment manufacturing industry, steel industry, petrochemical industry, food processing industry and bio-pharmaceutical industry. The latter requires Wuhan to implement the "four circles" strategy, as well as continue to promote the present industrial layout process. The "four circles" strategy mainly refers to the urban industry circle based on downtown within the Third Ring, the core industry circle between the Third Ring and The Outer Ring, the industrial circle made up of six distant suburban area and the industrial docking circle of “8 +1” city circle. Only by doing these can the advanced manufacture industry in Wuhan develops in a sustainable, fast and healthy way.

Determinants of Capital Structure of Chinese Manufacturing Firms: A Panel Regression Analysis

A.B.M. Munibur Rahman, Fang Qiang

School of Management, Wuhan University of Technology, Wuhan, P.R. China, 430070

(E-mail: munib_30@yahoo.com, fangqiang@whut.edu.cn)

Abstract: The research objectives of this paper is to whether firm specific variables affect capital structure decision and respond to the selected capital structure determining factors of Chinese manufacturing firms. Seven years' data from year 2004-2010 has been taken for analysis; a total sample of 196 Chinese firms from manufacturing industries—Food, Fuel & Power, Pharmaceuticals and chemicals, and Textile. A static balanced panel data regression model was used for analysis. The result of the model based on the Total Debt Ratio shows that Profitability, Liquidity and tax burden is significant at 5 percent level and inversely related to debt financing for Chinese firms which complies with the Pecking order theory. Firm's Size variable is positively associated for Chinese firms which comply with Trade-off theory. Operating risk is significant and positively associated for Chinese companies which is absolutely opposite of Trade-off theory. Industry dummy is found insignificant which indicates industries have no significant difference in their capital structure. Besides, this research also highlights the diverse impact of the capital structure determining factors in firm's overall leverage decision and in long term debt financing decision.

Key words: China; Capital Structure; Fixed Effect Model (FEM); Random Effect Model (REM); Corporation Finance, Panel Data Model

1 Introduction

The term Capital structure is commonly used in corporate finance. An ongoing debate in corporate finance concerns the question of a firm's optimal capital structure. Specifically, is there a way of dividing a firm's capital into debt and equity so as to maximize the value of the firm?

Financing and investment are two main activities undertaken by a firm. In the financing decision, the manager is concerned with determining the best financing mix or capital structure for his firm. Capital structure decisions affect a firm in two ways. Firstly, firms of the same risk class could possibly have higher cost of capital with higher leverage. Secondly, capital structure may affect the valuation of the firm, with more leveraged firms, being riskier, being valued lower than less leveraged firms. Thus, capital structure is an important decision for it could lead to an optimal financing mix which could maximize the market price of the firm.

The concept of optimal capital structure is expressed by (Myers, 1984, pp. 575-592) and (Myers & Majluf, 1984, pp. 187-221) based on the notion of asymmetric information. The existence of information asymmetries between the firm and likely finance providers causes the relative costs of finance to vary among different sources of finance. Apart from identifying the determinants of capital structure an important issue is defining what is meant by capital structure or leverage (Doukas & Pantzalis, 2003, p. 59) and (Mittoo & Zhang, 2005) amongst others define leverage as long-term debt scaled by total debt plus market value of equity.

The traditional trade-off argument postulates that optimal capital structure involves balancing the corporate tax advantages of debt financing against the present value of bankruptcy costs (Kim, 1978; Kraus and Litzenberger, 1973) and agency costs (Jensen and Meckling, 1976; Myers 1977). The empirical support for this argument is far from conclusive. For instance, while Bradley et al. (1984) find no clear evidence, Trezevant (1992) reports evidence supportive of this argument. Issues such as personal taxes (Miller, 1977) and non-debt tax shields (DeAngelo and Masulis, 1980) make the debate even more complicated. On the other hand, the Pecking Order Theory (Myers, 1984) suggests that firms do not have leverage targets and they use debt only when retained earnings are insufficient.

Manufacturing industry, Textile, garments and Multinationals are playing the crucial role at the economy of any country. Major Industry is dealing with about all the economic activity of a country. However, to do that organizations have to utilize their other financial resources efficiently. Consisting with that the intention of this paper is to explore the determinants of capital structure for selected companies of China.

2 Literature Review

Before the forthcoming paper of Modigliani and Miller in 1958, traditional view on capital structure lack the theoretical basis for making direct assumptions about the nature of the costs of debt and equity. The MM theory was revolutionary and changed market view forever. Although MM theory will not stand in a practical world which is obviously not perfect, it became a foundation for serious development of the currently popular capital structure theories such as Trade-off Theory, Static Trade-Off theory, Dynamic Trade-off Theory, Pecking Order and Market Timing Theory. Previous studies of capital structure determinants have found that corporate financial leverage is closely related to the business characteristic (Titman & Wessels, 1988; Harris & Raviv, 1991).

Rajan and Zingales (1995) found across the G7 group of countries that firms are more levered than in market-oriented countries and determinants of the capital structure that have been previously reported for U.S. data are equally important in other G-7 countries.

The determinants of capital structure choices are such as agency signaling costs (Heinkel, 1982; Poitevin, 1989), bankruptcy (Ross, 1977), taxes (Leland and Toft, 1996), institutional and historical characteristics of national financial systems (La Porta et al., 1997, 2006; Rajan&Zingales, 2003) but the understanding of the determinants of national and international capital structure is still limited and vague (Aggarwal & Jamdee, 2003).

Capital structure has been the core issue of a large number of corporate finance researchers. The history about empirical research on the determinants of capital structure in Western countries is much longer than the P.R. China. Here in China research arena, Chen (2004) and Huang and Song (2006) are notable studies to assess the capital structure theories in Chinese listed companies. Evaluating the explanatory power of capital structure theories in China is important because China is the largest developing and transitional economy in the world. Although Booth et al. (2001) have done research in developing countries including China, those countries using market-based economic models that are similar to developed countries.

Chen (2004) provides the study to examine whether and how the determinants of capital structure investigated in Western countries are also feasible in Chinese economy, where using firm-level panel data of 77 Chinese non-financial listed companies from the year 1995 to 2000. The methodology and determinants of that research refers to previous studies. Chen (2004) reports that the modern theories of capital structure, such as the tradeoff theory and the Pecking order hypothesis, are less applicable to the financing choice of Chinese firms. Due to the transitional nature and distinctive institutional features of publicly listed corporations, it seems to appear a new Pecking order for financing in Chinese firms. Internal fund is still the first consideration, then equity financing and lastly long-term debt choice in Chinese companies. Chen (2004) finds that financial leverage in Chinese firms decreases with profitability and it is consistent with existing literature. Additionally, growth opportunities and tangibility are positively related to debt in China.

Huang and Song (2006) exercise a new data set of both market and accounting value to analyze the capital structure models in more than 1000 Chinese listed companies over the period 1994-2000. In their research, they indicate the same findings as Booth et al. (2001) that firms in developing countries tend to have lower long-term debt. Moreover, 'as in other countries, leverage in Chinese firms increases with firm size, non-debt tax shields and fixed assets and decreases with profitability and correlates with industries'. However, results different from others is that debt in Chinese firms have a negative relationship with earnings volatility.

In very recent study, Qian et al. (2007) have examined the six determinants of capital structure for Chinese listed companies over the period of 1999-2004. The static panel-data models showed that firm size, tangibility and state ownership are positively related with firm's leverage ratio. However, factors such as profitability, non-debt tax shields and volatility have a negative relationship with the leverage ratio.

3 Methodologies

3.1 Sampling design and data collection

This paper deals with a developing country- China. Primary focus of this paper was the behavior of manufacturing companies, hence financial institutions were not considered in sampling design. Priority of sampling design was randomness and availability of data. Four manufacturing industries—Food, Fuel & Power, Pharmaceuticals and chemicals, and Textile— have been selected for analysis and companies under each industry have been selected randomly for Chinese companies. Seven years' data from year 2004-2010 was taken for both countries and for all the four industries. Total sample of 196 Chinese

companies has been taken out of which 26 was from Food industry, 50 from Fuel & Power industry, 79 Pharmaceuticals industry, and 41 from Textile industry. Quantitative analysis will be performed by using the software STATA (Version 11.1). MS Excel will be used also where it is necessary.

3.2 Empirical model

To begin with the analysis descriptive statistics were estimated and correlation among the variable were checked. A static balanced panel data regression model was used for analysis. The generalized form of regression equation is–

$$y_{it} = \alpha_i + \beta'x_{it} + u_{it}$$

Where,

$i = 1 \dots N$ and $t = 1, \dots T$

α_i : Constant

y_{it} : The leverage of the firm i and in year t

β : A $K \times 1$ vector of coefficients

x_{it} : A $K \times 1$ vector of explanatory variables

u_{it} : Error term

Specification of the model 1 with dependent variable Leverage1 (total debt to Total asset ratio) is given below–

$$\begin{aligned} \text{Leverage1}_{it} = & \alpha_i + \beta_1 * \text{Assetstructure} + \beta_2 * \text{Profitability} + \beta_3 * \text{Size} + \beta_4 \\ & * \text{Growthopportunity} + \beta_5 * \text{Operatingrisk} + \beta_6 * \text{Liquidity} + \beta_7 \\ & * \text{TaxBurden} + \beta_8 * \text{InterestRate} + \beta_9 * \text{MarketIndex} + \beta_{10} \\ & * \text{Industrydummy} + u_{it} \end{aligned}$$

Specification of the model 2 with dependent variable Leverage2 (Long-term debt to Total asset ratio) is given below–

$$\begin{aligned} \text{Leverage2}_{it} = & \alpha_i + \beta_1 * \text{Assetstructure} + \beta_2 * \text{Profitability} + \beta_3 * \text{Size} + \beta_4 \\ & * \text{Growthopportunity} + \beta_5 * \text{Operatingrisk} + \beta_6 * \text{Liquidity} + \beta_7 \\ & * \text{TaxBurden} + \beta_8 * \text{InterestRate} + \beta_9 * \text{MarketIndex} + \beta_{10} \\ & * \text{Industrydummy} + u_{it} \end{aligned}$$

Fixed Effect Model (FEM) and Random Effect Model (REM) were estimated and Hausman test was utilized to choose the appropriate model. Robustness of the estimated result was checked.

4 Result Analysis

4.1 Correlation analysis for Chinese selected industries

Table1 represents that the correlation among the different variables of capital structure determinants of China. Correlation coefficient is significant at $P < 0.01$ for all level of relation among factors for China. Here, leverage is significantly negative with profitability, tax burden and liquidity and others for positive value. It indicates that China industry depends on more equity financing and if more levered then they have to pay more tax. Other variables like interest rate. Growth and size indicates the mixed relationship among them. Ultimately the results enhance the strength of the study.

Table 1 Correlation for China Data

Variable	Leverage	Leverage	Profitability	Liquidity	Tax burden	Size	Growth	Market	Operation Risk	Interest Rate
Leverage	1									
Tangibility	0.1052	1								
Profitability	-0.3958	-0.1892	1							
Liquidity	-0.2726	-0.2219	0.1608	1						
Tax burden	-0.0273	-0.0574	0.0183	0.0135	1					
Size	0.1297	0.2026	0.1164	-0.1694	-0.0225	1				
Growth	0	0.0073	0.1987	-0.0212	0.0321	0.2397	1			
Market	0.0143	-0.0006	0.0622	-0.0444	0.061	-0.0454	0.0167	1		
Operation Risk	0.1356	-0.0203	-0.0459	0.1105	-0.0121	-0.3472	-0.1236	0.0403	1	
Interest Rate	0.0352	-0.0146	0.0363	-0.0318	0.0405	-0.1464	-0.0332	0.1422	0.1428	1

4.2 Empirical result analysis

In this section, represent the results of empirical analysis on the determinants of capital structure as mentioned earlier that Huasmen test, regression result with Fixed Effect Model (FEM) and Random Effect Model (REM) is used to analysis the study of capital structure determinants of china data.

Table 2 Regression Output of Chinese Firms Based on Two Models

Variable	Model-1: Dependent Variable Leverage 1 (Total debt to Total Asset Ratio)			Model-2: Dependent Variable Leverage 2 (Long-Term Debt to Total Asset Ratio)		
	Coefficient	S.E	P value	Coefficient	S.E	P value
Tangibility	0.1215714	0.180918	0.502	0.2437533*	0.083863	0.004
Profitability	-1.236467*	0.488087	0.011	-0.3732209**	0.213715	0.081
Liquidity	-0.0100325*	0.004755	0.035	0.0008386	0.001054	0.426

*Significant at 5 percent level

**Significant at 10 percentage level

FEM and REM is estimated and tested with Hausman test to select the best model and REM is selected. Robustness of the model is checked and final result is presented in the Table: 2).

For model-1 with dependable variable “leverage-1 (Total debt to total asset ratio)”, R square value is very small 25.5 percent which indicate lower strength of the variables included in the models in explaining the variability of leverage or capital structure decision. On the contrary, overall model is significant at 1 percent level—chi square test is significant at 1 percent level— indicates that the joint power of the variables included in the models are good enough to explain the behavior of leverage decision. Model-2 with dependable variable “leverage-2 (Long-term debt to total asset ratio)” shows the similar goodness of fit and overall significance of the model.

Tangibility: In model-1 Tangibility is not significant at even 10 percentage level which is a sharp contrast with both Trade-off theory and pecking order theory. Tangibility is significant at even 1 percentage level and the coefficient is positive for model-2 which complies with the trade-off theory. The coefficient shows a positive relationship which indicates that 1 unit rise in Chinese companies’ tangibility increases company’s capital structure decision of debt financing by 0.24 units. Trade-off theory suggests positive relationship between tangibility and leverage decision. This is because firms with more tangible asset are more capable of debt financing providing higher collateral.

Profitability: Profitability is significant at 5 percent level for Chinese companies for model-1 and is significant at 10 percent level for model-2. Both model shows that profitability is inversely related to total leverage and long-term leverage. The coefficient of model-1 indicates that 1 unit rise in Chinese company’s profitability declines company’s capital structure decision of debt financing by 1.23 units. Similarly, coefficient of profitability of model-2 indicates that 1 unit rise in Chinese company’s profitability declines company’s capital structure decision of long-term debt financing by 0.37 units. This finding suggests that profitable Chinese companies are more likely to finance internally through retained earnings than external financing via debt which complies with the systematic analysis of

pecking order theory. This finding sharply contrasts with the tradeoff theory which suggests profitable firms have greater exposure to corporate tax, lower possibility of bankruptcy, and more free cash flow related problems and firm can reduce tax burden and agency cost through debt financing.

Liquidity: Liquidity is significant at 5 percent level for Chinese companies for model-1 only. The coefficient shows an inverse relationship with debt financing which indicates that 1 unit rise in Chinese company's Liquidity negatively affects company's capital structure decision of debt financing by 0.010 units. This estimation indicates that firms with higher liquidity avoid external financing and prefers internal financing.

Tax burden: Literatures suggest impact of tax burden on capital structure decision is twofold. Companies have incentive to reduce tax burden by taking debt and conversely, revenues from debt are taxed heavily than revenue earned from equity. Tax burden is significant for both model-1 and model-2 and the coefficient shows inverse relationship. Hence, empirical result of this paper complies with the second viewpoint and shows an inverse relationship between tax burden and capital structure decision of both debt financing and long-term capital structure decision for Chinese firms.

Size: Firm's Size is significant at 1 percent level for Chinese companies for both models. The coefficient shows a positive relationship which indicates that 1 unit rise in Chinese companies' size increases company's capital structure decision of debt financing by 0.089 units, and 1 unit rise in Chinese companies' size increases company's capital structure decision of long term debt financing by 0.05 units. This finding suggests that large firms have greater capacity to absorb debt and better access to debt market than small firms which complies with trade-off theory and contrast with pecking order theory. Empirical studies, such as Marsh (1982), Rajan and Zingales (1995), Wald (1999), and Booth et al. (2001), generally find that leverage is positively correlated with company size.

Stock Market Condition: Result suggests that for stock market condition is statically significant for model-2, long term debt financing decision, at 5 percent level and the coefficient is positively associated. This finding suggests that good performance of shares in the stock market is used as virtual collateral to finance through long-term debt by Chinese companies.

Operation Risk: Operation Risk is significant at 5 percent level for model-1 but insignificant for model-2. The coefficient shows a positive relationship with debt financing which indicates that 1 unit rise in Chinese company's operation risk positively affects company's capital structure decision of debt financing by 0.0001 units. This estimation indicates that firms with higher volatility prefer external financing. This result is contrasting to both trade-off theory and Pecking order theory.

Industry Dummy: Industry dummy for model-1 shows that Industry type has insignificant differences in their capital structure decision of debt financing. Industry dummy shows that Industry type has significant differences in their long-term debt financing decision.

5 Conclusions

Capital structure considers of debated topics that increasing the concerning of financial economists. The research investigated the effect of the determinants of capital structure Chinese selected four industries (Food, Fuel, Pharmaceuticals and Textile) for period (2003-2010) by using FEM, REM and Huasmen Test model as regression technique. The determinants are selected based on two prominent theories of capital structure, static trade-off theory and pecking order theory. Previous studies have been analyzed to find the possible determinants. FEM and REM regression model for panel data with cross section random effects was run with two equations. Total debt to market value of the companies was used as the leverage ratio in one equation and long term debt to market value was used in another leverage equation.

Consistent with previous empirical researches, this study confirms that profitability has negative effect on capital structure. Fama and French (2002) and Myers (1984) use this fact to reject the static tradeoff model. However, Chang (1999) builds a new model within the agency-principal framework and its comparative static analysis shows that firm's leverage decreases with profitability. Here, in our research also find the same result as per previous empirical investigation.

The study also explores that Chinese listed companies leverage increases with company size, volatility of profitability, tangibility, and it decreases with profitability, tax burden. Sometimes Chinese companies tend to heavily rely on external financing, especially equity financing at the aggregate level (Huang 2005). Calculation from this study, the descriptive statistics shows that almost 50% leveraged financing. Findings from some papers that net equity issuance are negative in the United States during 1991-1993 (Rajan and Zingales, 1995). Also, Myers (1984) points out that, 62% of capital expenditures

came from internally generated cash flow for non-financial American companies during 1973-1982. Myers used such fact to justify the pecking order hypothesis. China is still holds their market economy and their capital financing policy is contrary with GAAP. That's why exploring the huge equity market with controlled financing. Chinese firm's capital structure decision partially depends on ownership structure.

At the end, the results will be more reliable if number of observations and variables can be increased for Chinese firms. China has huge market which is difficult to manage in depth. Personal traits of the managers such as their personal risk tolerance can have impacts on firms' capital structure decision. Further scopes are there to do similar studies by adding more observations and variables. Besides, further studies can also be directed towards finding the optimal capital structure.

Research on the Competitiveness Analysis Model of Industrial Cluster in High-Tech Industrial Zone

Zhan Yuanfang

School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070

(E-mail: diaozf@163.com)

Abstract: This paper argues that the main standard to the high-tech industrial zone's overall competitiveness is the competitiveness in industrial clusters. Based on the above consideration, according to the theoretical framework of Porter's diamond model, the paper built up the indexes system of high-tech industrial zones' industrial cluster competitiveness, which is closely combined with national environmental features of high-tech industrial development zones, and constituted by 7 secondary indexes and 26 third-level indexes. And the analysis model was established with the application of analytic hierarchy process and principal component analysis.

Key words: High-tech Industrial Zone; Industrial Cluster; Competitiveness Analysis; Evaluation System

1 Introduction

Energetically enhancing the competitiveness of high-tech industrial zone is related to our natural scientific and technological innovation strength and the development of high-tech industries. The main standard to the high-tech industrial zone's overall competitiveness is the competitiveness in industrial clusters. If the industrial clusters have apparently competitive advantages in the industry, then this high-tech industrial zone must also have prominent competitive advantages. Therefore, the establishment of the competitiveness analysis model of high-tech zone's industrial clusters is helpful in the scientific evaluation of high-tech zones' industrial clustering competitiveness, and can promote the formation and development of industrial clusters in high-tech industrial zones, which has important practical significance in enhancing the overall competitiveness of high-tech industrial zones.

2 Structure Path

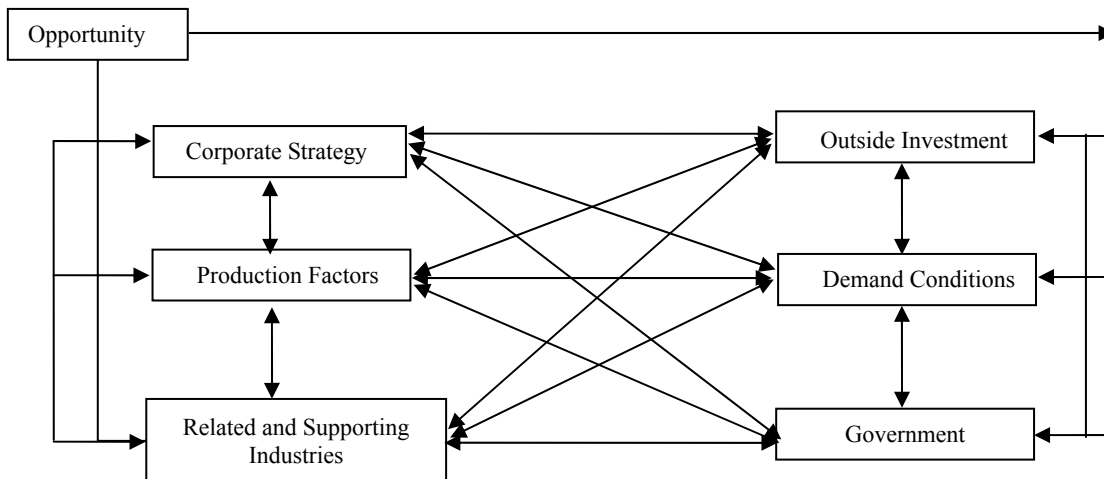

Figure 1 The Industrial Clusters' Competitiveness Model of High-Tech Industrial Zone

By summing the applicability and limitations of Porter theoretical model, in accordance with the theoretical framework of the Diamond Model, this paper further amends and extends the key elements that impacts industrial clusters' development of high-tech zones in building the competitiveness model of industrial clusters, which is closely related with national high-tech zones' features. Problems in clusters of high-tech zones are not only about the enterprises themselves, but closely related the government in site. Our national development in high-tech zones had short history, where still many deficiencies, therefore governments' guidance and support is needed.^[1] Moreover, the rapid development of high-tech zones heavily dependent on the investment from outside companies and governments. Therefore, in addition to

the four key factors that external opportunities production factors, demand conditions, corporate strategies and related and supporting industries, the role of government and external investment gets special consideration in this paper. Based on the above analysis, we constructed the industrial clusters' competitiveness model of high-tech zones, which is shown in figure 1.

Table 1 The Competitiveness Index System of Industry Clusters in High-Tech Industrial Zone

First-class index	secondary index
Production Factors	industrial employed population ratio
	average salary of industrial employees
	ratio of R&D employees to employed population
	living cost
	number of employees with master degree and above
	local universities' number
Requirement Condition	industrial yearly income
	growth rate of industrial yearly income
	industrial market share in nationwide
Enterprise's Strategy	enterprises' number in the industry
	yearly growth rate of enterprises' number in the industry
	the ratio of R&D fund to total income
	enterprise's management efficiency
Related and Supportive Industries	Financial support degree
	number of enterprises in cluster
	related degree with upside and downward industries
Government	support from local district government
	support from local provincial and city government
	support from national government
External Investment	investment mount from foreign countries
	growth rate of foreign investment
	direct investment mount in national investment
	growth rate of national investment
Opportunities	Development opportunities

3 The Building of the Competitiveness Index System

According to the analysis above, the paper builds the industrial clusters' competitiveness index system of high-tech zones from seven aspects: production factors, requirement conditions, Enterprise's strategy, related and supportive industries, external investment, government, and opportunities, which is shown in Table 1.

4 The Evaluation Method of the Competitiveness Index System

As the factors that affecting the industrial clusters' competitiveness of high-tech zones are numerous and complex relationship, the building of the competitiveness model is a typical multi-index problems^[2].

In this model, because first-class indexes are relatively independent to each other, AHP calculation is used to considering the weights. Various decision-making factors are analyzed by a combination of qualitative and quantitative processing. And the secondary indicators are related closely, so the principal component analysis is adopted to get a timely and concise economic process, which is conducive to seize the main contradiction and in-depth understanding.^[3]

4.1 Basic thoughts in AHP

This analysis method is a comprehensive analysis contains multiple levels' statistical research method. It makes analysis by adopted multiple index system with less comprehensive index method,

putting an economic problem into related N samples and P specific observation index. It can be drawn that P indicators are random vectors:

$x = (x_1 + x_2 \cdots x_p)^T$, therefore the sample matrix is:

$$x = \begin{bmatrix} \vdots & \ddots & \vdots \\ x_{n1} & \cdots & x_{np} \end{bmatrix}$$

And, $x_i = (x_{1i} + x_{2i} \cdots x_{ni})^T$, $i = 1, 2 \cdots p$.

Using the sample matrix x 's p vectors: $x_1, x_2 \cdots, x_p$, making linear combination, is:

$$F = a_1 f_1 + a_2 f_2 + \cdots + a_m f_m$$

This equation has the following two conditions: firstly, F_i and F_j is not correlation ($i \neq j, j = 1, 2 \cdots, p$); Secondly, F_1 is the biggest variance in the linear combination of $x_1 \cdots, x_p$; F_2 is the biggest variance among the linear that not related with F_1 's $x_1 \cdots, x_p$. And deduce like this, among $F_1, F_2, \cdots, F_{p-1}$, the biggest one is F_p .

4.2 Calculation process in principle component analysis

There are n samples and p observation variants in the model, therefore, complexity correlation in sample(x_{ij}) ($i = 1, 2, \dots, nj = 1, 2, \dots, p$) decides the complicated relationship among sample statistics. Using a simple method, by confirming m common factors, as let $F_1, F_2, \cdots, F(m \langle p)$ substitutes the complex information among the observation variables.

Common factor F_1 can be statistically expressed by observation variable x_{ij} :

$$F_1 = \sum_{j=1}^i b_{ij} x_{ij} \tag{1}$$

Variance contribution rate is:

$$c_i = \lambda_i / \sum_{i=1}^p \lambda_i \tag{2}$$

and, λ_i is the i common factor's characteristic root in the sample matrix X . Setting A is the sum of variance contribution rate,

$$A = \sum_{i=1}^m c_i \geq 85\% \tag{3}$$

Therefore, the sample score can be calculate by m common factors:

$$S = \sum_{i=1}^m F_i c_i / \sum_{i=1}^m c_i \tag{4}$$

Assuming there are k first-class indexes in this paper, and the calculation equation for first-class index S_k is:

$$S_k = \sum_{i=1}^m F_i c_i / \sum_{i=1}^m c_i \tag{5}$$

4.3 The basic idea of analytic hierarchy process

Analytic hierarchy process is a model of thinking in essential. This method is based on the scientific analysis and decomposing the complex issue into a series of indexes or factors, which are then re-decomposed into secondary or third-level and so on. After the layering, the comparison methods are used to study the weight of each-level's indexes and factors.

4.4 The calculation processes of analytic hierarchy process

The calculation processes can be divided into four steps: Firstly, establishing the total level system; secondly, building the comparison matrix among indexes; Thirdly, confirming the ratio relationships among indexes; lastly, listing the ratio of each index to the total index.

5 Conclusion

This paper argues that the industrial clusters' competitiveness index system of high-tech zones is not only related to external opportunities, enterprise's strategy, production factors, requirement

conditions, related and supportive industries, but also affected by government policies and external investment. The above seven aspects can be separately expressed by a number of secondary indicators. Therefore, the competitiveness index system of industry clusters in high-tech industrial zone can be built by 7 first-class indicators and 26 secondary indicators. Finally, the industrial cluster's competitiveness analysis model of high-tech industrial zones can be established by the combination of AHP and principal component analysis.

A Study on the Marketing Channel Mode Innovation of Traditional Chinese Medicine Enterprises*

Guan Cuiling, Zu Guoqiang, Liu Hui, Qiu Yinggui

School of Management, Hubei University of Chinese Medicine, Wuhan, P.R.China, 430065

(E-mail: guancl@hbtc.edu.cn, 871148558@qq.com, 1047740750@qq.com, 465927652@qq.com)

Abstracts: With literature study and case analysis, this paper provides an in-depth analysis of existing main marketing channel modes of some typical traditional Chinese medicine enterprises of China, such as Kanion pharmaceutical, Shineway pharmaceutical, Dong'e E-Jiao, Tong Ren Tang. It argues that there are some common problems in these enterprises, for example, unreasonable channel structure, serious unauthorized distribution, low channel management level, the ineffective management of terminal market and so on. Based on the analysis of problems, some countermeasures for improving the marketing channel modes are put forward. Future research direction and implications for managing marketing channel are subsequently discussed.

Key words: Marketing channel mode; Marketing channel innovation; Marketing channel management; Traditional Chinese medicine enterprises; Case analysis

1 Introduction

Marketing channels are 'the sets of interdependent organizations which, by an exchange of outputs, are involved in the process of making a product or service available for consumption' and include organizations involved in manufacture, brand ownership, wholesale and retail (Reve T., Stern L.W., 1979).^[1] Marketing channel research is predominantly conducted in the Western world, marketing channel theories and practices may not be generalizable to Chinese markets. Despite the rapid growth of Chinese economies and their increasing importance to the global economy, the understanding of marketing channels in China is limited. This research reviews and integrates studies of marketing channels in the pharmaceutical context. We find the research on pharmaceutical marketing channels focuses on the channel mode, channel conflict, and channel relationships.

1.1 The study on medicine channel mode

According to the traditional theory of marketing channel structure, channel marketing channel is composed of a series of independent institutions and organizations, which have clear target and independent interest. In fact, these seemingly independent institutions are dependent on each other. Due to the interdependence between the marketing channel organizations, marketing channel should be regarded as a network system (Doyle J.D., Bottomly P.A., 2006).^[2] Since the marketing process is becoming more and more complex, the potential economic benefits of coordinated marketing system has become increasingly apparent (Rangan V.K., 2006).^[3] The enterprise can use the company type, management type and contract type three ways to effectively coordinate marketing channel system (Kaplan A., 2006).^[4]

In China, some scholars proposed that Chinese pharmaceutical enterprises combined the typical channel mode according to their characteristics. These enterprises take a variety of channel model, such as dealers' group system, distribution system combining direct channel, direct marketing system, etc. Chinese pharmaceutical enterprises mainly take the investment agent system and the system of factory outlets. From new medical reform perspective, they analyzed the advantages and disadvantages of these channel models. The mainstream pharmaceutical marketing channel model was pyramid, which had some disadvantages, such as high cost, lack of control, functions weakened, poor management, and so on (Wang Y., Yao Y.P., 2011).^[5]

1.2 The study on channel conflict

Channel conflict is that a channel member thinks that the other members harm its legitimate interests, and affect the realization of its aim. Conflicts often manifested as other non cooperative and malignant commercial behavior (Stern. L.W., El Ansary A., 1996).^[6] Mirroring the movement towards the relationship marketing paradigm, Hopkinson G.C., Blois K. (2013) considers the theory's empirical contribution to knowledge of power, conflict, trust and commitment in marketing channels.^[7]

* This paper is supported by Humanities and social science research base of Hubei Province College: The Research Center of TCM development.

In China, some scholars summarized the causes of medical channel conflict. For example, Wang Y., Yao Y.P. (2011) pointed out both internal and external factors of enterprise caused the channel conflict, and the difference in interest between channel members is the main cause of medicine channel conflict.

1.3 The study on medicine channel relationships

Many scholars explored the importance of cooperation and coordination in marketing channels (Payan J.M., 2007).^[8] Zhuang, G., Xi Y., El Ansary A. (2008) explored the impact of inter-personal Guanxi on exercise of power in a Chinese marketing channel.^[9] Some scholars put forward that the relationships between channel members could achieve a transaction from a simple transition to relation by integrating the entire product supply chain and strengthening channel members relationships. Channel members could reduce the cost of sales, increase the operating profit, and improve the comprehensive benefits of marketing channels by constructing the stable channel alliance (Li K. F., 2011).^[10]

Although Scholars have conducted the related research to the medicine marketing channel, there is not special research on marketing channel mode of **traditional Chinese medicine (TCM)** enterprises. Because TCM enterprise marketing channel mode is special, we should make the theoretical research of the marketing channel mode of TCM enterprises in the future, and put forward the channel modes which are consistent with the actual situation of TCM enterprises in order to provide theoretical support for the improvement of mode of enterprise channel of TCM.

2 Analyses of Main TCM Channel Modes

There are four marketing channel modes of TCM enterprises, including the agent system, regional distribution system, direct marketing system, and direct and distribution system. With the development of TCM industry, TCM enterprises should innovate marketing channels. Their Channel modes are not confined to a single channel mode, but combination of several modes. This paper will analyze the main channel modes taking several typical TCM enterprises for example.

2.1 Agent system

Agent system refers that TCM enterprises choose to cooperate with one or several pharmaceutical commercial enterprises, which help the distribution of products, the development of sales channels, the establishment of marketing network, product marketing and after-sales service.

1) The type of agency. Agent system according to the area is divided into provincial, municipal, county agent system. According to the number of agents within the same region, agent system can be divided into exclusive agent system and multi-agent system.

2) The analysis of Shineway pharmaceutical agent system. Shineway pharmaceutical centralizes TCM product R&D, production, sales. Then we shall analyze its marketing channel mode.

Figure 1 Shineway Pharmaceutical Channel Mode

According to its product characteristics, Shineway Pharmaceutical uses the Trinity channel model which relies mainly on the agent system. The using of agent system makes their products quickly enter the target market, increases market coverage, lowers sales and administration costs. Due to excessive levels of lead, it is difficult to manage channel and control channel. Because a lot of channel members maliciously compete, it is difficult to control the price of the terminal. The channel conflict causes to damage the interests of channel members and reduce its channel members' loyalty.

2.2 Regional distribution system

Regional distribution system is that TCM enterprises in a specific area select one or more pharmaceutical commercial enterprises as its middlemen, which help to develop target market, and use its resources to develop new markets and promote product sales.

1) Regional distribution system type. According to the number of pharmaceutical commercial

enterprises within the same region, regional distribution system can be divided into total dealers and distributors system.

2) The analysis of Kanion pharmaceutical regional distribution system. Kanion pharmaceutical is a TCM corporation which provides products R&D, production and trade of TCM enterprises. Then we shall analyze its marketing channel mode.

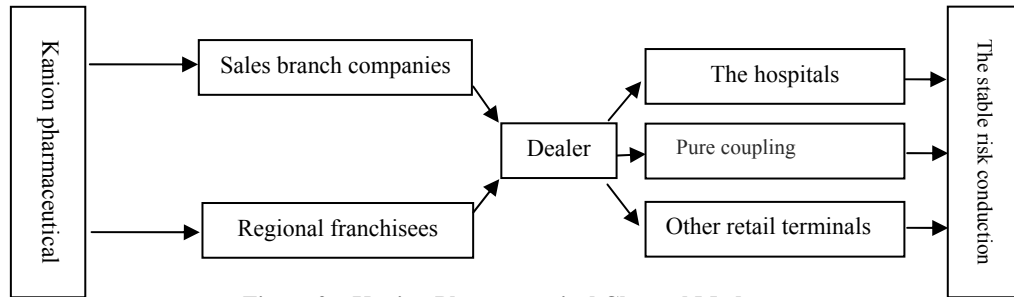

Figure 2 Kanion Pharmaceutical Channel Mode

The distribution system is Kanion pharmaceutical’s main channel model. Kanion pharmaceutical cooperates with 150 pharmaceutical business companies. There are primary dealers 150-160, two distributors 700-800. The cooperation between distributors and sales help to achieve rapid product distribution, and establish strong sales force, strengthen the links with the terminal, and improve the understanding and monitoring of the market. Meantime, the distribution system may bring a lot of problems, for example, sales channels is too long, which led to more channel inventory, low profitability, excessive huge sales offices, high management fees, serious fleeing goods problems, product terminal sales price confusion.

2.3 Direct marketing system

Direct marketing system is that TCM manufacturers without the channel intermediaries (agents, distributors, retailers), through self-built network, including the entity shop and network shop sell TCM products directly to consumers.

1) The Direct marketing system’s type. According to the direct way, it can be divided into entity shop and online shop franchise.

2) The analysis of Tong Ren Tang’s direct marketing system. Tong Ren Tang is a company engaging in TCM product development, production, sales and provision of medical services, and its mode of marketing channels is following.

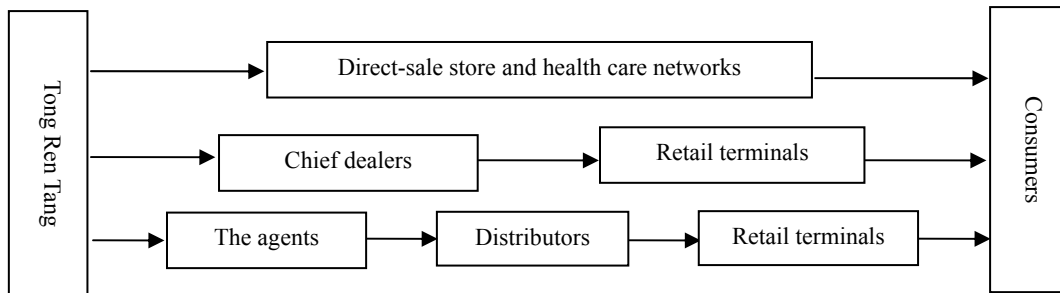

Figure 3 Tong Ren Tang Channel Mode

The direct retail channel and the traditional agency are Tong Ren Tang’s main model. It takes the chief dealer system for the weak products. Its sales network is throughout the country. It has the cooperation relationships with many domestic pharmaceutical business companies, and has more than 1500 franchise stores and more than 130 medical service networks. The using of direct system speeds up the product distribution, erects a direct channel of communication with consumers, and accurately grasps the market dynamics. Since the establishment of its many shops, the sales investment is huge, the management is difficult.

2.4 Combination of direct and distribution System

Combination of direct and distribution system refers that the TCM production enterprises’ distributors include dealers and retailers. In order to achieve rapid product sales, expand market share, TCM production enterprises combine with the distributors and retailers for product sales.

1) The type of combination of direct and distribution System. In accordance with the enterprise

channel focus, it can be divided into two combination system. One is based on distribution system, and the other is based on direct system.

2) The analysis of Dong'e E-Jiao binding system. Dong'e E-Jiao Co. Is a TCM production enterprise which provides production and sale of TCM product, health care products? Then we shall analyze its marketing channel mode.

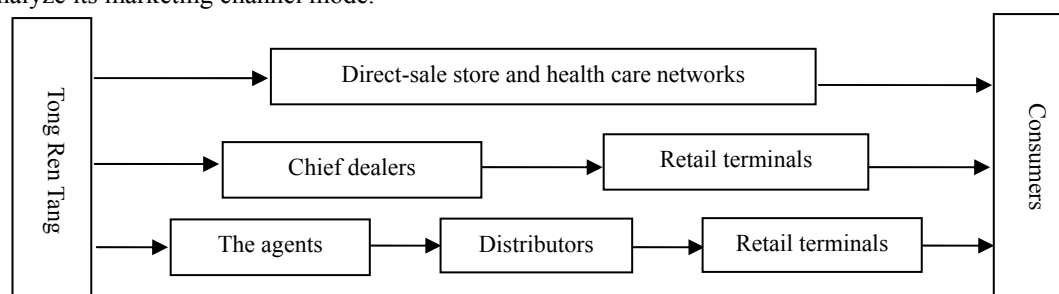

Figure 4 Dong'e E-Jiao Channel Mode

Dong'e E-Jiao mainly adopts distribution system and direct system. It uses the traditional form of networks in the distribution system, at the same time, it provides product for domestic large chain pharmacies through its own direct sales force without middlemen. The direct and distribution system helps to accelerate the sales of the products, establish a platform to communicate directly with consumers, accurately grasp the market dynamics. But there are some disadvantages. At first, it results vicious competition in product distribution process. In the second, it is difficult to manage channel members, and it does not attach importance to the development and maintenance of relationships. Thirdly, it is difficult to control product terminal price.

3 The Problems of Chinese Medicine Channel Mode

Because of the different situation of TCM enterprises, the problems of their marketing channel modes are complex and diverse. This paper combines some typical TCM enterprises, sums up the existing problems of the channel mode, and put forward the common problems of TCM enterprise channel mode.

3.1 Unreasonable channel structure

At present, the majority of TCM enterprises use regional dealer system or agent system, they usually choose distributors or agents in a particular region, for example, Shineway pharmaceutical's marketing channel levels up to level 4 or above, this results that the channel management is very difficult, members' control force is weak, the cost of sales and management is high, market information communication is not smooth. These problems are the common problems of Chinese Medicine channel pattern.

3.2 Serious fleeing goods

Fleeing goods is a common problem of TCM enterprises in product sales, which is general and serious. In order to guarantee the rapid distribution of products, Shineway pharmaceutical, Kanion pharmaceutical etc. usually choose a lot of distributors or agents. But in order to seek self-interest, some dealers sail goods across regions, which causes the market strife and price confusion, makes it difficult to control the terminal price, and also causes the enterprise reputation suffered serious damage.

3.3 Low channel management level

TCM enterprises are at a low level in the channel management and their management is unscientific. In channel management there are some common problems, such as business orientation. Enterprises do not attach importance to the development and maintenance of retail terminal, neglect the channel members training, ignore the relationship between channel members, take improper channel member incentive measures, and so on, which seriously restrict the development of TCM products and TCM enterprises.

3.4 Poor terminal management

First of all, the medicine retail terminal construction is not perfect, which restricts TCM product sales in all. Secondly, the attention on the retail terminal is insufficient. TCM enterprises only attach importance to product sales; do not pay attention to the relationship. In addition, the distribution of sales terminal resources is uneven. The difference between urban and rural is large. In short, terminal sales of TCM products are not perfect and poor management, which restricted the product sales.

4 The Countermeasures to Improve the Channel Mode

The improvements of channel mode of TCM enterprises should start from the existing problems. Combining with its actual situation, TCM enterprises should establish a marketing channel mode fitting the characteristics of its product. In this paper, combining with typical TCM enterprises, in view of their common problems, we will put forward some concrete countermeasures.

4.1 Integration of channel structure

First, flatten the channel structure. TCM enterprises should integrate the structure of marketing channel through making the gravity of the channel down, shortening the channel level as far as possible, reducing the length and width of the channel, adopting wide-short channels. This simplification can not only reduce the cost of sales, but also establish the rapid reaction mechanism, strengthen the control of the channel, reduce inventory in the channel, speed up the product distribution, and increase profitability of enterprise. In addition, make the channel links electronic. TCM enterprises should build modern management information system, establish perfect, smooth and rapid information channel, and improve the efficiency of product supply and distribution.

4.2 Strengthen the management of the fleeing goods

In order to solve this problem, in terms of products, provide code for each product to strict distinction; accurately grasp the product in order to control cross-regional fleeing goods. In terms of price, set strict price system, including clear ex-factory price, total price, the secondary distributor price, retail price, and provide the corresponding profits for the dealers at all levels. In terms of dealers, TCM enterprises can ask the dealer to strictly obey the contract to carry out business activities. In channel management, strengthen the channel member management, formulate strict and trans-regional punishment system, and punish fleeing goods.

4.3 Scientific management of channel members

To carry out scientific management of channels, the first thing is to introduce advanced management concept and methods. On the choice of channel members, strict selection criteria should be formulated; regional resources, sales and business reputation of the channel member should be taken into account. At the same time, regular professional training of channel member is necessary, which can enhance their identity on products and enterprise, and improve the loyalty. On the other hand, TCM enterprises should establish new type of channel relationship with pharmaceutical commercial enterprises and drug retailers, form the channel alliance. Finally, TCM enterprises should determine appropriate and reasonable incentive system of members, strengthen the sales enthusiasm of channel members, and build TCM products supply and marketing value chain together.

4.4 Pay attention to the terminal market

The importance of terminal market is increasingly attached by TCM enterprises. Tong Ren Tang spent a huge sum of money to build stores, to set channel gravity of the terminal down, to promote the rapid sales of the products. it is a successful stories. For the TCM enterprise which don't have the capability to build own terminal, measures should be taken by strengthening links with the retail terminal and making a meticulous terminal market, such as setting the systematic promotion plans according to the management characteristics of the retail terminal, strengthening cooperating relationship, forming the brand chain mode of cooperation to make up for the shortage of this aspect.

5 Conclusions

Basing on the understanding of pharmaceutical marketing channel, combining with some typical TCM enterprises, including Kanion pharmaceutical, Shineway pharmaceutical, Dong-e E-jiao, Tong Ren Tang, we analyze the current situation of TCM enterprises' channel mode deeply, summarize the problems of channel mode. We think that their channel structure is not reasonable, fleeing goods is serious, channel management is not science, terminal construction is not proper, management is poor. We suggest that TCM enterprises should integrate the channel structure, strengthen management of the trans-regional channels, do fine terminal market, and take other measures to relieve the existing problems of TCM channels to promote the sale of products and TCM enterprises' long-term development. At the same time, TCM enterprises should apply related marketing theory to guide the improvement of their marketing channel mode.

In the future, in terms of research on the channels of TCM enterprise, we should further improve the channel mode theory; build a systematic improvement project of channel mode. We should pay attention to channel relationship and channel conflict, and build perfect theory system of TCM channel.

Abstract: Creative industry has become a new economic growth point and the principal aspect of the competition of comprehensive national strength. Creative industry is a talent-intensive industry which stresses individual creativity and innovation. This paper discusses the definition and characteristics of creative talents of the creative industry, applies the combination forecast based on ant colony optimization algorithm to build a new creative talents demand forecasting model, and uses the statistical data of personnel in culture industry of Heilongjiang province to make empirical prediction. Empirical analysis indicates that the forecast model can improve the overall performance of the combined forecasts and meet the actual demand of the creative industry's development for creative talents.

Key words: Creative talents; Combination forecast model; Ant colony optimization algorithm

1 Introduction

Under the background of the knowledge economy era, creative industry, as an emerging industrial development, has raised a wave of economy and made huge economic contribution all over the world. According to the data provided by Hawkins in the book of 'Creative Economy', the global creative economy creates the value of \$22 billion every day, increasing at the rate of 5%. A number of countries have regarded the creative industry as an emerging strategic industry and taken measures to promote the development of creative industry. Creative industry is knowledge-intensive, culture-intensive, technology-intensive and talent-intensive industry, the core of resource is creativity and innovation, therefore, the high-quality of creative talents with the distinctive characteristics of creativity and innovation is the key factor to accelerate the development of creative industry, promote the growth of creative economy, and motivate the prosperity of creative city.

With the booming of the creative industry, the demand for creative talents is also increasing. Although demand forecasting is of the utmost importance in creative industry planning and policymaking for both the public and business sectors, applications of combination forecast methods remain rare. There is great significance about the research on creative talents demand forecasting, on the one hand, to promote the balance of supply and demand of the creative talents, make sure that the development strategy of creative industry can be implemented successfully. On the other hand, by means of the analysis the development trend of the demand, provide important reference value for the government and creative business sectors to make the policy and planning, strengthen the creative industry management, at the same time, to arouse endogenous power of the creative economy and lay a solid talent basement.

In this article, we define the definition of the creative talents and analyze the characteristics from three aspects. Then, we take the creative industry of Heilongjiang province as an example and construct the combined forecasting of which the optimal weight is solved by employing the ant colony optimization algorithm. By means of the prediction error, we verify the effectiveness of the combined forecasting. Finally, we forecast the creative talents demand of Heilongjiang province in the next five years, which is meaning for the better implement the strategy of creative industry and creative talents in Heilongjiang province.

The rest of the paper is organized as follows. Section 2 outlines general notions of creative talents. Section 3 presents a complete description of combined forecasting based on ant colony optimization algorithm. Section 4 provides the results of prediction for the creative talents demand of Heilongjiang province. Section 5 provides the conclusions.

2 The Definition and Characteristics of Creative Talents

2.1 The definition of creative talents

Creative talents are also known as the creative class that was first put forward by Florida(2002). He divided creative class into two parts: Super creative core and Creative professionals. Research on creative talents of China began in 2004. Different researchers defined the concept from various angles. From the viewpoint of talent type, Li(2007) considered creative talents as the elite talents, who owned independent intellectual property rights as the core, characterized by brain work, depended on professional or special skill. From the viewpoint of labor, Zeng(2011) regarded creative talents as the brain workers, who provide high added-value products or services by means of creativity and professional skill.

Above researchers defined the concept from different viewpoints, which provide an essential reference for this article. Based on the above research, this paper defines creative talents from the multi-viewpoint, creative talents refer to the talents, who possess creativity, high level knowledge, innovation spirit and innovation ability, engage in creative activities related to all aspects of the creative industry chain, turn knowledge, inspiration, idea or information into high added-value products or services by means of creativity and profession skills. Creative industry chain includes three stages, creative planning design, creative production and marketing. According to the stages, creative talents can be divided into three kinds of type, creative designers, creative producers and creative marketers.

2.2 The characteristics of creative talents

Although creative talents engaged in different jobs, there are some characteristics in common, such as character trait, job characteristic and geographic feature.

1) Character trait: With knowledge and high quality, the creative talents have creativity and innovation, and usually have inspiration and innovation idea and engaged in creative work. So due to such trait, members of the creative talents tend to be young and generally higher education levels. Furthermore, the creative talents possess shared values, such as respecting personality, cherishing freedom, emphasizing the realization of self-value and self-identity.

2) Job characteristic: The creative talents work mainly in the form of team, because that from an idea or inspiration to high added-value products or services, the process of creative industry development needs many different professional creative talents to complete. Moreover, good working environment affects the creative talents greatly. Creative talents regard job as only a part of life rather than the whole life. So, besides salary, they also pay attention to the cognition of supervisor, colleague relationship, work meaningful and flexibility, good prestige, company's policy and culture and so on.

3) Geographic feature: The creative talents have higher demand for urban living conditions, and tend to be gathered in the creative cities. Florida put toward the noted '3T' (Technology, Talent, Tolerance) theory of creative economic development. Then, another 'T'(Territorial assets) was added, this is so called '4T' theory. Glaeser proposed '3S'(Skill, Sun, Sprawl) theory, which also stressed the quality of place was meaning for creative talents, such as the 'sunbelt' is the important factor to attract the creative talents.

3 Method

3.1 Combination of forecasts

The concept of combination forecast started with the seminal work of Bates and Granger(1969). Given to individual forecasts of a time series, they demonstrated that a suitable linear combination forecasting may result in a better forecast either of the two original ones, in the sense of a smaller error variance. Throughout the years, applications of combination forecast have been found in many fields such as meteorology, economics, sales and price (Clement, 1989). The empirical results of the study (Song, 2009) show that combination forecasting is statistically significantly more accurate than the average single-model forecasts for all combination method. This provides a strong recommendation for forecasting talents demand in a creative industry.

Basically, given a set of single forecasting method from $i=1$ to n over m time periods $t=1$ to m , X_{it} , the problem is to determine the fixed weights W_i over the m periods for each forecasting method $i=1$ to n , which give the minimum squared forecast errors for the actual data values Y_t ($t=1$ to m). This can be formulated as a QP problem with the weights as the decision variables as follows:

$$\begin{aligned}
 & \text{Minimize} && \sum_{t=1}^m \left(\sum_{i=1}^n W_i X_{it} - Y_t \right)^2 \\
 & \text{Subject to} && \sum_{i=1}^n W_i = 1 \\
 & && W_i \geq 0
 \end{aligned} \tag{1}$$

The key of combination forecasting is how to choose the weight. Much work has been done on finding the optimal fixed weights for individual forecasts to minimize the within sample sum of squared forecast errors, such as Simple Average (*AVG*), Variance based (*VAR*), Inverse of the mean square error (*INV-MSE*). Deutsch, Granger et(1994) pointed out that updating weights produced substantially smaller out-of-sample squared errors than those obtained by fixed weights.

This paper further investigates the impact of combination forecasting on forecast accuracy by applying the ant colony algorithm to determine the combination weights for the signal forecasts.

3.2 Combination forecasting model based on ant colony algorithm

Ant colony optimization algorithm based on the foraging behavior of ants has been first introduced by Dorigo and Gambardella. The basic idea of ACO is to imitate the cooperative behavior of ant colonies. As soon as an ant finds a food source, it evaluates it and carries some food back to the nest. During the return trip, the ant deposits a pheromone trail on the ground. The pheromone deposited, the amount of which may depend on the quantity and quality of the food, guides other ants to the food source. Quantity of pheromone on the arc is decreased in time due to evaporating. Each ant decides to a path or way according to the quantity of pheromone. More pheromone trail consists of short path than long path. The technique is based on updating pheromone trail of good solutions and there are many ant models in this way. Continuous ACO algorithm has been introduced and used for optimization of benchmark functions and creative talents demand estimating.

First, transform a continuous search space to a discrete one by differentiating the continuous decision variables, which are so-called the continuous ACO algorithms (CACO). In this investigation, the CACO for the traveling salesman problem are modified to determine three parameters of a combination forecasting model as Eq.(1) in the discrete search space. The probability, $p_k(i, j)$ that an ant k moves from city i to city j is expressed as Eq.(2)

$$p_{ij} = \frac{\tau_{ij}}{\sum_{i=1}^n \tau_{ij}} \tag{2}$$

Where τ_{ij} is the pheromone level between city i and city j .

Once ants have completed their tours, the most pheromone deposited by ants on the visited paths is considered as the information regarding the best paths from the nest to the food sources. Therefore, the pheromone dynamic updating plays the main role in real ant colonies searching behaviors. The local and global updating rules of pheromone are expressed as Eq.(3)

$$\tau_{ij}(t+1) = \tau_{ij}(t) + \frac{Q}{f(i)} \tag{3}$$

Where $f(i)$ is the length of the shortest route.

More detail of the CACO procedure algorithms on this study is as follows:

- Initialization: Set upper bounds of three positive parameters. In this study, in order to discretion those continuous parameters, each digit of the parameters is represented by 100 cities, as follows Eq.(4). Thus, each digit contains 100 equally possible values from 0 to 1. Hence, three ant colonies are defined as W_i -ant colony for three parameters value searching. The numbers of cities for each ant colony are 101.

$$W_{ij} = W_{i \min} + \frac{(W_{i \max} - W_{i \min})}{100} \times j \tag{4}$$

- Assigning tasks to each ant colony: For step one, pathway-structure list of ant-colony would be generated. Each ant will randomly select a pathway from the pathway list in its associate colony and remember the values of the represented parameters. At end of the pathway, pass the three parameters values into the objective function and calculate the forecasting error. The shortest travel pathway in each searching loop would be determined based on the smaller forecasting error.

- Determine the numbers of ants and calculate the distance between cities: The numbers of ants are set to be 101 in each ant colony searching. The maximum number of iterations is set to 1000 to avoid infinite iterations.

- Stop criterion I: While the maximum number of iterations is reached, then stop the algorithm and the shortest travel path of the ants colony is an approximately optimal solution. Otherwise, continue to step 4.

- Calculate the visiting probability: If the maximum number of iterations is not reached, then calculate the probability that an ant k in city i moves to city j in accordance with Eq.(2). Repeat steps 1-3;

- Stop criterion II: If each ant has finished its pathway-structure list from the nest to the food source passing through all cities, then, the shortest path is an approximately optimal solution. Otherwise, conduct the pheromone updating process represented as to Eq.(3) to renew the reinforcement of pheromone, then ,go back to step 4

Notice that, in any iteration, while the shorter path is attained, the appropriate solution is determined, and for those parameters, new search space is then re-discretized.

4 Empirical Results

4.1 Data

There some agreement among academic researchers that the ‘hard core’ of creative industries branches include: Advertising, Architecture, Arts and antiques, Crafts, Design and designer fashion, Video, Film, Music and Photography, Visual and performing arts and music, Publishing, Computer games, Software and electronic publishing and radio and TV. Due to the difference of statistics in different areas, the data of creative talents is scarce. So, this article regards the personnel engaged in cultural industry as the creative talents, which occupies a large proportion in the creative industry, and adopts the data provided by Heilongjiang statistical yearbook. Table 1 lists the number of personnel in cultural industry in Heilongjiang province from 2002 to 2011.

Table 1 Number of Personnel in Culture Industry (Unit: Person)

Year(t)	2002	2003	2004	2005	2006
Number	12768	12700	12304	12574	12704
Year(t)	2007	2008	2009	2010	2011
Number	14297	14022	14517	16245	17416

4.2 Results of forecast models

This article adopts three single forecast models, respectively, Moving Average prediction model(MA), Exponential Smoothing prediction model(ES) and Gray prediction model($GM(1,1)$) to predict the creative talents demand of Heilongjiang province. Table 2 presents the actual value and predict values, as well as the Relative Error.

Table 2 The Predicted Values and Relative Error of Individual Forecasts

Year (t)	Actual Data (Person)	Predicted Value (Person)			Relative Error (%)		
		MA	ES	GM(1,1)	MA	ES	GM(1, 1)
2005	12574	12471	12329	12814	0.82	1.95	1.90
2006	12704	12539	12454	13388	1.30	1.97	5.39
2007	14297	13070	12634	13988	8.58	11.63	2.16
2008	14022	13830	14141	14614	1.37	0.85	4.22
2009	14517	14215	14378	15269	2.08	0.96	5.18
2010	16245	14825	14823	15954	8.74	8.75	1.79
2011	17416	16106	16456	16669	7.52	5.51	4.29

According to the above analysis and calculation, among of the three single prediction models, some prediction accuracy has been very accurate, but even so, in the different years, their performance prediction effect is still very unstable. So, based on the data provided Table 2, a combination forecasting is set up as follows:

$$\begin{cases} \min & Q = e_1^2 + e_2^2 + e_3^2 + e_4^2 + e_5^2 \\ s.t. & \sum_{i=1}^3 W_i = 1 \\ & e_1 = 14297 - (13070W_1 + 12634W_2 + 13988W_3) \\ & e_2 = 14022 - (13830W_1 + 14141W_2 + 14614W_3) \\ & e_3 = 14517 - (14215W_1 + 14378W_2 + 15269W_3) \\ & e_4 = 16245 - (14825W_1 + 14823W_2 + 15954W_3) \\ & e_5 = 17416 - (16106W_1 + 16456W_2 + 16669W_3) \end{cases} \quad (5)$$

Applying the improved ant colony algorithm to calculate the weights of each model, we get the weights as follows:

$$W_1 = 0.26 \quad W_2 = 0.27, \quad W_3 = 0.47$$

4.3 Performance of combination forecasting model

In order to validate the combination forecasting model is effective, we choose two indexes, Mean absolute percentage error (MAPE) and Root mean square prediction error (RMSPE) to evaluate the prediction effect, as follows Eq.(6) and Eq.(7). According to the above two error indexes calculated respectively three individual predictive error indexes and combination forecasting error indexes, the result as shown in Table 3.

$$e_{MAPE} = \frac{1}{n} \sum_{t=1}^n \left| \frac{P_f - P_a}{P_N} \right| \times 100\% \quad (6)$$

$$e_{RMSPE} = \sqrt{\frac{1}{n} \sum_{t=1}^n \left(\frac{P_f - P_a}{P_N} \right)^2} \quad (7)$$

Table 3 The MAPE and RMSPE of Prediction Results for Different models

	MA	ES	GM(1,1)	Combination Forecasting
MAPE	4.12%	4.36%	3.16%	2.58%
RMSPE	5.26%	5.73%	3.60%	3.08%

According to information of the table the two error index values of MAPE and RMSPE, the combination forecasting model error index values is significantly lower than the two individual forecasting model error index values. Thus shows that this proposed combination forecasting method can effectively increase the prediction accuracy.

4.4 Creative talents demand of Heilongjiang Province

By analysis and comparison, the combination forecasting model based on ant colony optimization algorithm has excellent accuracy, so this model can be used to predict creative talents demand of Heilongjiang province in the next five years, the predicted result is presented on the Table 4.

Table 4 The Creative Talents Demand of Heilongjiang Province (Unit: Person)

Year (t)	2013	2014	2015	2016	2017
Number	19419	19011	19863	21683	22655

According to the predicted result, the creative talents demand will increase at a steady growth rate. In order to prevent creative talents become the bottleneck of creative industry development, some measures are needed to take to promote the creative talents growth.

First, the local government should realize the importance of creative talents from strategically highlight, formulate a long-term program for creative talents development, as well as make a macro adjustment and policy planning so as to achieve the balance of supply and demand. Second, reform and improve the creative talents cultivating mechanism, accelerate the training of inter-disciplinary talent with specialty, capability and knowledge, who are not only proficient in creative industry but also skilled in creative management. Last, strengthen the cultivation of professional talents in the universities and colleges. Pay attention to train innovative education and original consciousness, promote the path of combining industry-university-research cooperation in Heilongjiang Province.

5 Conclusion

Creative talents who possess the traits of creativity, high level knowledge, innovation spirit and innovation ability are the key factor to accelerate the development of creative industry. The article has explored the definition and characteristics of the creative talents and put forward a new combination forecasting method based on ant colony optimization algorithm. The method is tested with the data from the number of personnel in cultural industry in Heilongjiang province. Empirical results indicate that the proposed combination forecasting can improve the forecasting accuracy effectively and provide an important reference for the government decisions in the development of creative industry.

Industrial Competitiveness and Industrial Ecology: Case of RING Initiative in Japanese Oil-Related Industry

Yoshiyuki Matsuura, Kazuya Inaba, Nguyen Huu Phuc

Graduate School of Innovation and Technology Management, Yamaguchi University
(E-mail: matu@yamaguchi-u.ac.jp, inaba@yamaguchi-u.ac.jp, phuc@yamaguchi-u.ac.jp)

Abstract: This paper analyzes the reorganization and reformation of the Japanese petro-related industry and industrial complex. Japanese petro-related companies have struggled to compete with foreign competitors enjoying overwhelming economy of scale and promoted business integration beyond firm's boundary for regaining competitiveness. The industry and Ministry of Economy, Trade and Industry jointly initiated a national project to address this issue by facilitating technology development for achieving highly efficient industry complex both economically and ecologically. By applying stag hunt game approach, we discuss the condition for successful coordination project and describe how subsidizing and business environment affect the coordination effort, which previous industrial ecology research fails to investigate.

Key words: Industrial ecology; Petrochemical complex; RING; Stag hunt game

1 Introduction

Assuming value maximization as firm's objective and stable regulatory constraints on environmental issue, energy and material conservation effort of firms cannot apparently come before economic rationality consideration, although energy conservation literature has insisted setting environmental objective having equal importance to economic one^[1]. Economic theory indeed doesn't preclude environment preserving activities, even when short term economic impact is uncertain, as far as those affect expected economic value which is the product of sustainable growth in the future. As energy saving activity and facility and /or product's energy efficiency can achieve competitiveness and thus economic value to firm at least short term, energy efficiency at macro level can be enhanced through competition. As such, Japanese industrial sector, with strong support from governmental body, had long been praised for achieving a balance between financial performance and energy/material efficiency by advanced technology^[2].

Despite overall favorable impression on the progress of the energy conservation efforts, Japan is still on the way to entrench energy/material exchanges, among geographically co-located firms, beyond organizational boundary which make up eco-industrial region in aggregate, so called industrial ecology¹². Previous research found multilateral energy/material exchange, including reuse of waste heat, water and by-product within a region evolved spontaneously, mainly driven by economic reason^[3,4], despite in reality industrial ecology efforts being mainly led by public sector^[5-7]. The literature meanwhile observes economic benefit works as stimuli but doesn't enhance mutual exchange itself and stress the importance of social capital or social proximity among corporate managers as decisive factor^[8,9], drawing much attention to social embeddedness of industrial ecology^[10]. Although we assent the importance of soft factors, analyzing those in isolation from economic benefit masks interrelation between economic factors and non-economic factors and successful industrial ecology cases give inaccurate impression of product of chances contingent on players' characteristics.. Standard finance theory tells us how to handle those soft factors within economic analysis. "Trust" or "openness" between stakeholders can resolve information asymmetry and suppress opportunistic behavior, consequently decreasing discount factor for a project which in turn raises likelihood of agreement on exchange.

¹ Eco town program, being inspired by "Zero emission research initiative," is a notable example. The program was initiated jointly by METI and MOE in 1997 and according to METI, it pursers the goal of "the construction of a resources-recycling economic society through the development of industrial industries by utilizing local industrial accumulations, the prevention, and the promotion of recycling of wastes based on the uniqueness of local districts"⁽¹²⁷⁾, p.2).

² The regional eco-efficient industrial system is sometimes referred to as "industrial symbiosis." We don't use this terminology intentionally as most cited definition by Chertow^[28] states "Industrial symbiosis engages traditionally separate industries in a collective approach to competitive advantage involving physical exchanges of materials, energy, water and/or by-products" (p.2). Our scope is broader and do not require the separation of industries among exchanging firms.

Nevertheless, existing industrial ecology studies concluded successful cases achieved remarkable economic performance as well as environmental load reduction from ex post analysis^[11-13]. Such case studies, while demonstrating best practice, only touched the tip of the iceberg and failed to analyze negotiation process toward exchange and thus incorporate risk inherent to coordinative projects. Moreover, those studies focused on economy of inter-firm exchange but did not pay attention to intra-firm alternatives, a noteworthy exception being done by Wolf et al^[14]. Intuitively, firms may prefer in house competing project if it would generate lesser economic benefit^[15]. There might be therefore enormous negotiations on multilateral exchange ending in failure even when (risk adjusted) economic benefits are expected while mutual understanding being fully nurtured. Given this, simple questions arise. How much expected economic benefits a project should have for reaching agreement? To what extent does required economic benefit in the absence of mutual trust differ from that in the case of strong trust? Is a firm indifferent between in-house project and cross-boundary one when competing projects have equivalent value?

To the best of our knowledge, only few previous researches, such as Andrews^[16] and Rozen et al^[17] with applying transaction cost economics framework, shed light on the factors which affect the fortune of negotiation over multilateral exchange in the context of industrial ecology. We developed analytical framework to investigate economic threshold which coordinative project should satisfy for filling this gap, reflecting on our involvement in a regional industrial ecology project^[18]. Although it may seem contradictory on the surface, this framework helps designing political measures to promote industrial ecology. Political initiative for industrial ecology implies the existence of untapped exchanging opportunities. Given the spontaneous nature of industrial ecology evolution, governmental initiative should not be interventive but supportive by means of subsidizing and creating forum to communicate. As far as additional industrial ecology provides public benefits, public spending for compensating coordinative risk acceptance can be justified but should be cost-effective. As discussed later, our framework gives guideline to determine adequate subsidy and further proposes intermediating value transfer between prospective firms by public sector or third party can raise likelihood of agreement with the given amount of subsidy.

Industry characteristics can significantly affect firm's attitude toward industrial ecology, more generally coordinative effort. Tightly coupled business activities between co-located firms can enhance information exchange and nurture trust which drive industrial ecology. In this sense, industrial agglomeration consisting of process industry such as petro-related industry, by its nature of process connectivity, would likely develop multilateral energy/material exchange spontaneously, as the agglomeration gets matured. However, contrary to widely held view^[19], Japanese petro-related companies had historically preferred individual energy saving effort and for beating price competition they had developed highly eco-efficient production system individually by developing unique energy conservation technology and technique, given relatively small factory size from global standard. Considering path dependency of system evolution, switching cost from intra-firm optimized system from regionally optimized system becomes excessive high, especially if the transition would take considerable time, making co-locating facilities reluctant to coordination. Although additional energy conservation effort can contribute to competitive advantage to some extent, newly established mega-scale petroleum and petrochemical complexes in emerging countries which realize overwhelming economy of scale soon blow such incremental energy saving effort away. Japanese petroleum and petrochemical companies as well as petro-related industrial complexes faced such severe competitive environment around the turn of the century, due to the declining domestic demand and accompanying excess capacity. From company's perspective, promoting coordinative project within existing local industrial region requires higher strategic justification than industrial ecology, as they have economically promising option of establishing sophisticated manufacturing unit abroad. This is particularly true for Japanese petro-related industry because they have mainly used costly naphtha as material for ethylene instead of ethane. Thus, as Esty and Porter^[20] stressed, even local material and energy flow optimization may not contribute competitiveness of corporation.

Meanwhile Japanese petro-related industry in unison created cooperative initiative called "RING (Research Association of Refinery Integration for Group-Operation)" to enhance the industry competitiveness and preserve local industrial complex supported by the government in 2000¹. Industrial ecology related projects, such as by-product multilateral exchange, were developed among others. As

¹ We analyzed RING initiative in the context of longitudinal evolution of petro-related industrial complex in Inaba^[29] and Inaba et al^[30].

will be shown, achieving industry ecology has not been the main objective of the initiative but has been pursued spontaneously (yet somewhat collaterally) for economic reasons, namely surviving in highly competitive global marketplace.

The purpose of this essay is to describe the progress of RING initiative referring to the analytical framework mentioned above. By doing this, we intend to analyze the progress of the industrial ecology within so called brownfield in the context of revitalization of matured industry, to which prior studies didn't give considerable attention. Next section introduces the analytical framework, generalized stag hunt game. Section 3 briefly describes RING initiative. Section 4 discusses the progress of RING within the framework and proposes further research.

2 Analytical Framework

We extended and generalized stag hunt game framework to analyze coordination problem. While some of prior studies adopted game theoretic approach to planning and evaluation of competing industrial ecology ^[21-23], our research focus on the economic condition of successful pre-investment process. Coordination negotiation, as can be seen in M&A cases, takes considerable time. Due to technological development, change in internal or external business environment, either party may find more attractive option or insufficient benefit reflecting production cutback even after agreement and thus the coordination can break down. Our framework allows examining the impact of those possible dynamics onto coordination. The following three factors are crucial in developing the framework:

- (1) Post-investment net amount of coordinative benefit
- (2) Pre-investment risk of coordination
- (3) Existence of other investment alternatives, particularly opportunities of intra-firm investment

It is obvious that coordinative benefit must be high enough to tempt firms into the joint project (factor 1). In the conventional literatures, the assessment of the coordinative benefit is based only on the post-investment cost and benefit. However, because coordination is considered critical to the success of the project, coordination related pre-investment factors like coordination related losses should be included in the analysis (factor 2). Moreover, the project will fail ex-ante if a firm moves alone to other internal opportunity which is expected to bring higher profit. Therefore, in general analysis, firms should be given the right to compare and choose their decisions of participating in the joint project or conducting its own internal investment (factor 3). Analyzing the spontaneity of coordination with or without this assumption will give different results. The novelty of our framework attributes to the inclusion of factor 2, referred as abortive coordination loss, which allows us to analyze the effect of social factors, transaction costs and internal investment opportunity set (including energy saving investment) in the context of coordination problem.

In game theory, coordination problem arises when coordination yields a net positive benefit to be divided between the partners, but it reduces a partner's payoff, if his counterpart does not coordinate. The simple version of this type of game is the stag-hunt game ^[24]. Stag-hunt game depicts a situation in which two hunters must decide independently whether to hunt the stag together or hunt rabbits alone without knowing the counterpart's attitude toward the coordination. Meanwhile, each hunter can get a rabbit by himself. Half a stag is better than a rabbit, but he must cooperate with his partner in order to succeed in hunting a stag. There are two rational outcomes (two Nash equilibria) for this game: hunters together hunt stag as a team, or each hunts a rabbit by oneself. Each would prefer to cooperate in hunting the stag, but if the other player's motives or actions are uncertain, the rabbit hunt is a risk-free alternative.

One concept for determining the equilibria in this kind of game is called payoff dominance that focuses on the payoff level of each equilibrium. Hence, an equilibrium payoff dominates or is more efficient than the other equilibrium, if and only if each player's payoff is greater in the former equilibrium.

However, during real negotiation process, whether to coordinate or not depends on not only their payoffs expected to be earned post investment but also abortive coordination losses if one partner withdraws, which can alter the equilibrium. Chassang ^[25] states that, by introducing incomplete information (i.e. risk) as ex post coordination to dynamic game analysis, "Payoffs upon miscoordination, which play no role when considering the Pareto efficient frontier under complete information, determine the extent of the efficiency loss (p.997)." Thus we exploit different equilibrium concept, called risk dominance which allows analyzing the effect of coordination risk on equilibria determination. Risk dominance concept intuitively depicts a situation where each participant is not sure whether the other

participant will play appropriate role in the equilibrium requiring coordination and then she may be motivated to choose the safer but less efficient equilibrium, given the existence of two Nash equilibria in a game. Technically, it is related to the risk associated with each equilibrium yet its estimation does not require the knowledge of participation probabilities (or the related distribution function) exogenously. With this setting, we formally show that there is always critical economic value for a coordinative project which motivates players moving to risk dominance equilibrium but coordination can fail even when all the relevant information are available. On the other hand, possibility of coordination will increase, *ceteris paribus*, by 1) transferring some portion of benefit between players, 2) changing the proportion of investment cost each player bears, 3) receiving subsidy from somewhere and 4) changing project size.

The interest of this paper is to examine the effect of abortive coordination loss, the product of coordination failure loss for each player, on the evolution of coordinative project within a (industrial and geographical) space over time. Broader strategic uncertainty of each player, for instance the uncertainty of continuous operation of a player, can largely affect the success probability of regional coordinative effort. While a challenge that players perceive in common, water shortage in outstanding industrial ecology case of Kalundburg, Denmark ^[12], can reduce abortive coordination loss, region specific issue by itself can drive coordination to the limited extent unless stable external environment. RING project highlights how broader challenge reduces abortive loss and nurtures industrial ecology.

3 RING Initiative of Japanese Petro-Related Industry

3.1 Background

Japanese petro-related firms had quest for cost advantage for surviving in fiercely competitive global marketplace. In the latter half of the 1990's, industry reorganization had developed, while they had simultaneously continued efficiency improvement at production site level. Positive investments in core business and growth business and participation in foreign industrial complexes had accelerated business integration and made reasonable contribution to enhance competitiveness. Nevertheless, the average scale of Japanese was not equal to their rivals oversea. Many companies were still independent and production facilities of even an individual company dispersed nationwide, mainly across eight industrial complexes, presumably due to the government's industry strategy. As such, Japanese petro-relate companies faced the reality of mediocre cost efficiency due to medium-scale production, excessive competition, surplus of production scale, and all of these factors resulted in disappointing low financial and stock price performance. Besides, coordinative efforts between production facilities belonging to different companies but locating in the same industrial district were underdeveloped due to the organizational, cultural and cognitive obstacles.

Meanwhile they had to address energy security and saving issues reflection of the two Oil Crises, given resource poor Japan's status. They had dealt by developing recycling technologies and consequently environmental and energy saving technologies of Japanese industrial sector, including petro-related firms, have been praised throughout the world. However, petro-related companies felt that further improvement in energy efficiency would not be achieved with isolated efforts. Accordingly, twenty companies in oil industry and chemical industry together to establish Research Association of Refinery Integration for Group-Operation (RING) in 2000 under the Research Association of Technology Law. RING, in close cooperation with METI, has facilitated group-operation projects in industrial complexes. The projects include unified management system and latest technologies development for achieving the goal of virtually single large scale regional production facility. Kashima, Chiba, Kawasaki, Chita, Sakai Senboku, Mizushima, and Shunan industrial complex developed coordinative projects in the context of RING initiative. RING initiative has gradually progressed in three stages so far, while the goal of each project at each stage varied reflecting uniqueness of each industrial complex. The first R&D projects (RING 1) had achieved certain results which worked as the proof of coordinative R&D potential in the each district. It had resulted that strong unity was caused among complex enterprises through these activities. Following this, the second R&D project (RING 2) was executed in 2003. Development of advanced, highly integrated technologies for reducing environmental burdens was performed there. In addition, the action to optimize entire petrochemical complex and carry out advanced function unification was executed in the third R&D project (RING 3) in 2006.

Only common interest could not cultivate coordination. METI thus decided to subsidize attractive projects as trigger and support the Association to mediate business cooperation yet indirectly for ensuring spontaneous and bottom up efforts. With this institutional setting, member companies started

personnel exchange, information sharing and analyzing operation flow with each other for exploring untapped opportunities. Beyond traditional energy saving and efficiency enhancing project, innovative ideas have spurred resulting in an upward spiral through cooperation between enterprises beyond the limit of single company business (See exhibit3).

3.2 Antecedent: Formation of Kashima Industrial Complex

The idea behind RING initiative was inspired by the successful coordinative operation in Kashima complex, one of the latest developed complexes. Open discussion field among participating companies examining the complex-wide issues was strategically organized at the earlier phase of its formation in the late 1960's, by Mitsubishi Chemical Corp., the dominant player in the complex. Kamesaburo Ikeda, the president of Mitsubishi Chemical Corp of the time, who had the considerable share of the credit for petrochemical industry development post WWII, was visionary enough to think about the long term development of the region as well as petro-related industry in Japan from the planning phase. Given the geographical and follower's disadvantage of Kashima region at that time, one of crucial tasks for him was to formulate real "industrial complex" more than simple neighboring which provided investing companies with international competitiveness through highly coordinated production flow, including joint ancillary facility and energy servicing entity, in close cooperation with Ibaragi prefecture. Among those joint facilities and companies, Kashima Joint Facilities Corp, which was established for resolving the conflict of interest among the co-locating business units and is still only one company specializing in managing/maintaining shared facilities of industry complex in Japan, represents systematically planned development in Kashima.

Ikeda particularly placed the importance on creating the opportunities where participating companies discussed district-wide issues at multilevel, from top executives to site workers. Exhibit 4 presents the current structure of promoting information sharing and coordination in Kashima. Corporate Liaison Council in Kashima Seaside Industrial Zone, which is steering body to enhance information sharing and discussion among companies, consists of "General meeting" (all companies), "Operational committee" (nine representative companies), "Environmental standing committee" (12 representative companies), and "Harbors standing committee" (11 representative companies). Senior executives of the representative companies assemble on a regular base (every two months) in Tokyo for discussing problems observed in the field. At middle and lower level, "Factory Meeting Committee," which is composed of "Six Companies Committee", "Administration and Environmental Measures Report Committee," "Labor Report Committee," "Production Report Committee," "Technological Report Committee" and "Security Measures Report Committee," proactively nurtures personal communication on site. Together with "Factory Meeting Committee," there is "Security Measures Liaison Council" ("Manager Committee" is under that). According to the function of their jobs, personal interchanges with same departments of other companies have been promoted in the Kashima complex. The development and interests of the Kashima complex has been shared in the field. Under such a system, they have undertaken actions on some problems, every day operations, and adjustment of regular repair etc. since establishing the complex. They have known well the circumstances of other companies, and always have recognized the advantage of joint management. The member companies naturally started to examine the possibility of multilateral energy and material exchange. METI decided to support the project and disseminate to other districts as a national project.

3.3 Progressive industrial ecology and industrial integration driven by RING

RING 1 projects (total project cost: 20 billion JPY) focused on developing foundations for integrated operation by establishing operation information sharing system, with the aim of nurturing a sense of community among members. RING2 promoted to develop technologies for efficient energy consumption and by product utilization toward industrial ecology. RING 3 aimed to progress coordinative technology development toward total optimization within industrial complex.

For instance, in Kashima industrial complex, Kashima Oil Co. and Mitsubishi Chemical Corp., as RING 1 project, undertook development of integrated operation technology allowing extensive utilization of refinery and petrochemical by-product, for enhancing mutual effective use of by-product material. And they succeeded to enlarge added-value of by-products. RING 2 projects in Kashima went further to execute research in which they efficiently collected olefin fraction of petrochemical raw material from off-gas generated as a by-product at the Kashima Oil facility. The result of this study is expected to be used as high-value-added raw material in the petrochemical sector. RING 3 project was to include other 2 companies and to create technology for highly efficient integrated production of petroleum and petrochemical products, by desulfurizing naphtha within the complex and then optimally isolating and supplying light naphtha fraction, which is materials for aromatic series in petroleum

refinery and ethylene and propylene in petrochemicals through efficient continuous distillation for relieving crude oil price risk.

These collaborative projects certainly encouraged firms to integrate operation further. For instance, Idemitsu Kosan and Mitsui Chemical established a LLP managing ethylene production facilities of both firms in Chiba complex in 2010. Another example was observed in Mizushima complex which led to management integration. Nippon Oil and Japan Energy started business partnership between contiguous refineries in 2006 and Nippon Oil and Nippon Mining Holdings, the parent company of Japan Energy commenced management integration in 2010.

4 Discussion

In the industrial ecology terminology, RING initiative purses to apply the successful planned eco-industrial park model to brownfield and transform it into efficient industry complex. It is still too early to evaluate the achievement of the initiative yet we can safely argue its progress is worth to observe for investigating how and why the initiative affects the transformation path of each industrial complex differently. However, in general, the idiosyncratic evolution trajectory of Kashima complex as a strategic niche implies transformation cost of brownfield, in our words abortive coordination loss, is expected to be high.

Our framework predicts coordination type of sharing utility/infrastructure or utilizing joint provision of services which is expected to be naturally organized for economic reasons^[25, 26], has relatively low abortive coordination loss and thus likely emerges at first phase of industry ecology formation. There are two reasons for that. First, after facility construction, even without coordination, one of them can still use the invested facility. Second, the overall effects from sharing utility/infrastructure are greatly reduced if the project is implemented by a single party (like fire-fighting equipment). The efficient operation in Kashima had not been secret to the industry members for long. The firms locating at Kashima complex has simultaneously have been operating at the other industrial districts together and the successive executives of those firms had met regularly and shared the information about the progress and the economics of the coordinated complex. If firms co-locating at other district which also operate in Kashima perceive the advantage of coordination over switching cost, such effort should already have to be observed. In reality, even coordination like Kashima Joint Facilities Corp mentioned above had hardly emerged in other districts, except joint power plant establishment with electric utility company.

Given this, political concern, to be cost effective, is to find critical value for coordination and subsidize project for filling the gap between the critical value and the expected project value. Although RING initiative commenced with less challenging and easy-to-operating projects jointly, reportedly many member companies were skeptical of the remarkable success of the initiative. Thus METI subsidized two thirds of project cost for RING project much higher than one half for typical coordinative energy saving project for alluring the firms. Even allowing for RING projects were not installation of existing technology but rather technology development thus risky, high subsidizing rate might reflect perceived high abortive coordination loss and presumably long term strategic objective behind. However, while our analysis supports more attractive subsidizing for coordinative project in general, high cost effective coordinative projects often turn out to have relatively high financial benefits of which concerned entities likely agree to cooperate even without subsidies. Our analysis thus predicts standardized grant tends to malfunction since it only gives excess benefits to attractive projects. This theoretical result suggests standardized subsidization differentiated the stakeholders' evaluation of the project across regions, which in turn affected abortive loss of succeeding coordinative projects. For instance, RING 1 intended to develop foundations for integrated operation like Kashima. In accordance to this objective, subsidizing ratio for Kashima, where abortive coordination loss might be low, should be lower if political objective is to evenly promote industry ecology.

Drastic industry reorganization changes rule of game and can promote coordinative efforts. However, it should be noticed that strategic importance of each industrial complex may affect abortive coordination loss in a mixed way. In other words, national or firm-wide level optimality consideration suppresses regional optimizing efforts. As there had been excessive ethylene production capacity, petro-related companies should inevitably eliminate and consolidate at least some ethylene plants which are the core of the complexes and should reconfigure regional supply chain network. Indeed, in the last few years, companies operating ethylene production announced shutdown or consolidation one after another and closure of the core facility would let co-locating firms move away. As coordinative material

exchange requires long term commitment to the participants, perceived possibility of the shutdown among players may raise abortive coordination loss. If RING member companies had considered regional optimization insofar as corporate level optimization enhancement while executing technology development in each complex had been a given, then project selection was largely affected by high abortive loss. The complex with high possibility of continuation would exploit more challenging and regional specific efficiency enhancing project. On the other hand, when the complex facing high uncertainty, for relieving abortive coordination loss, may tend to choose more generic project bringing temporal benefit and free from commitment of specific players. Consequently, even if the all development projects succeeded, the discrepancy of the degree of regional efficiency and industrial ecology will be enlarged between industrial complexes.

Industrial ecology and regional competitiveness are the two sides of a coin, especially for heavy industries. Thus industrial ecology research not counting for dynamics in business environment may keep the concept of industrial ecology stay in theory or at best observed eco-industrial regions as exceptional niches. Nevertheless we still

believe political initiative can turn brownfield into highly efficient eco-industrial park, but policymakers should pay enough attention to outside region dynamics as well as internal conditions. Comparing the longitudinal evolution and reformulation of Japanese petroleum and petrochemical complexes and investigating the consequence of RING will provide plenty of implications for putting industrial ecology into practice.

5 Conclusion

This paper applies generalized stag hunt game perspective to the progress of RING initiative. The efficient subsidizing strategy given different evolution trajectory of each industrial complex and the dynamic interaction between regional industrial ecology and industry reorganization, which the most extant literature fail to investigate, are argued. Theoretical description developed in this paper should be augmented with quantitative analysis yet we believe our theory offers the generic framework to investigate industrial ecology in business context. Although we don't discuss in this paper, our theory also predicts the existence of available internal energy projects and value transfer among players can affect the success of the coordination.

Abstract: This article collected and dealt with the dates of real GDP, capital formation, employment of 31 provinces, municipalities and autonomous regions in China between 2003 to 2011, through the unit root test, cointegration test and the model specific selection, utilizing the panel data model to get the Production Function, calculated total factor productivity(TFP) and its growth rates; then, bring “Index of Comprehensive S&T Progress”, surveyed by the Development Planning Department of National Ministry of Science and Technology, into the Production Function of panel data model to analyze the function and influence of “Index of Comprehensive S&T Progress” to TFP.

Key words: TFP; Panel data; Production Function; Index of Comprehensive S&T Progress (CSTP)

1 Introduction

The experience of the development of developed countries suggested that progress of S&T is the driving force of economic development, at the same time, the needs of the development of economy promotes the progress of S&T fundamentally, meeting with the development of the economic and social has become the target for the development of S&T, and the trend of interactive integration of S&T and economy is more and more obvious.

TFP (Total Factor the Productivity, TFP) is one of the important tools to study economic growth, and reflecting the technological progress of a country, region or industry, an enduring topic in the field of research of economic growth.

How to analyze and quantify the interactive integration of S&T and economy through econometrics model, and to promote this interactive integration with adopting the corresponding policies and measures, is a new problem in the field of macroeconomics. This paper intends to bring “Index of Comprehensive S&T Progress”, surveyed through 34 indexes by the Development Planning Department of National Ministry of Science and Technology, into the Solow Production Function, to analyze the function and influence of “Index of Comprehensive S&T Progress” to TFP, and to explore the preliminary quantitative interactive integration of S&T and economy.

2 Models, Method and Data Description

2.1 Panel data model

Panel data model are mainly the following three categories:

(1) Pooled Regression Model:

$$Y_{it} = \alpha + \beta X_{it} + \mu_{it}, \quad t=1, 2, \dots, T, \quad i=1, 2, \dots, N \quad (1)$$

(2) Individual-Mean Corrected Regression Model:

$$Y_{it} = \alpha_i + \beta X_{it} + \mu_{it}, \quad t=1, 2, \dots, T, \quad i=1, 2, \dots, N \quad (2)$$

(3) Unrestricted Model:

$$Y_{it} = \alpha_i + \beta_i X_{it} + \mu_{it}, \quad t=1, 2, \dots, T, \quad i=1, 2, \dots, N \quad (3)$$

To choice the kind of model will depend on the covariance analysis to check the following two assumptions:

$$H_1: \beta_1 = \beta_2 = \dots = \beta_N \quad (4)$$

$$H_2: \alpha_1 = \alpha_2 = \dots = \alpha_N, \quad \beta_1 = \beta_2 = \dots = \beta_N$$

Test statistics F_2 of H_2 is submit to the F distribution, namely:

* This paper is supported by Key Research Base of Humanities and Social Sciences of College in Hubei Province—Manufacturing Industry Development Research Center on Wuhan City Circle; by “Research on the Comparing and Improvement of the Index of Comprehensive S&T Progress of Hubei Province”, the project of Science and Technology Department of Hubei Province(2012GDA02101).

$$F_2 = \frac{(S_3 - S_1) / ((N-1)(k+1))}{S_1 / ((N(T-k-1)))} \sim F((N-1)(k+1), N(T-k-1)) \quad (5)$$

Test statistics F_1 of H_1 is submit to the F distribution, namely:

$$F_1 = \frac{(S_2 - S_1) / ((N-1)k)}{S_1 / ((N(T-k-1)))} \sim F((N-1)k, N(T-k-1)) \quad (6)$$

In (5) and (6), S_3 , S_2 and S_1 are the sum of squared residuals in (1), (2) and (3), N is the number of cross section, T is the times and k is the number of independent variables.

In addition, the stability of data must be considered in the process of regressions, that is whether the data have the unit root. Only the data have the same order, can the data enter the regression equations. If no stability, the data should be handled by difference.

2.2 Data description

Variable of output, were the regional real gross domestic product(real GDP, was nominal GDP multiplied with the consumer price index); capital, were the regional actual gross capital formation (actual capital K , total capital formation multiplied by the price index of investment in fixed assets); and labor, were the regional employment (L).

All the data come from annual statistical data of 2004 ~ 2012 of National Bureau of Statistics and monitoring data of progress of science and technology from 2004 to 2012 of Chinese Statistics¹.

2.3 Production function

Suppose the production function is:

$$Y_{it} = A_i L_{it}^{\alpha_i} K_{it}^{\beta_i} \quad (7)$$

Y_{it} , L_{it} , K_{it} respectively were the output, the inputs of capital and labor of region i in t period; $i = 1, 2, \dots, 31$; $t = 1, 2, \dots, 9$, respectively region s and periods; α_i and β_i respectively were the output elasticity of capital and labor; A_i was TFP of region i .

To take logarithm on both sides of (7), get:

$$\ln Y_{it} = \ln A_i + \alpha_i \ln L_{it} + \beta_i \ln K_{it} \quad (8)$$

Using the Panel Data Model to (8), the output elasticity of labor α_i and capital β_i can be gotten. Then making regularization:

$$\alpha_i^* = \frac{\alpha_i}{\alpha_i + \beta_i}, \quad \beta_i^* = \frac{\beta_i}{\alpha_i + \beta_i} \quad (9)$$

The TFP is:

$$TFP_{it} = \frac{Y_{it}}{L_{it}^{\alpha_i^*} K_{it}^{\beta_i^*}} \quad (10)$$

The rate of TFP growth from t_j to t_k is:

$$tfp_{it_i \sim t_j} = \left(\frac{TFP_{it_j}}{TFP_{it_i}} \right)^{\frac{1}{j-i}} - 1 \quad (11)$$

2.4 Production function contains “index of comprehensive S&T progress”

There are two intensions of S&T Progress: one is the progress of scale and level of S&T activities; the other is the progress of the influence of S&T on economic development. To monitor the status of activities of S&T in nation and regions, the Comprehensive Evaluation System of S&T progress², including 5 indicators of Level 1 (Environment of Progress of S&T, Inputs of S&T Activities, Outputs of S&T Activities, Industrialization of High and New Technology, and S&T to Promote Development of Economic and Social), 12 indicators of Level 2 and 34 indicators of Level 3 such as “Number of Professional and Technical personnel per ten thousand people”, was built by Development Planning Department of National Ministry of Science and Technology.

Put “Index of Comprehensive S&T Progress” into the production function (a region's “Index of

¹ <http://www.stats.gov.cn/tjsj/ndsj/>, <http://www.sts.org.cn/tjbg/tjjc/tcindex.asp>

² <http://www.docin.com/p-87803495.html>

Comprehensive S&T Progress” in period t):

$$Y_{it} = A_i T_{it} L_{it}^{\alpha_i} K_{it}^{\beta_i} \tag{12}$$

To take logarithm on both sides of(12)and regression with Panel Data Model, the output elasticity of labor α_i and capital β_i will be gotten; then normalization like(9), the $TFP2$ including “Index of Comprehensive S&T Progress” is:

$$TFP2_{it} = \frac{Y_{it}}{L_{it}^{\alpha_i} K_{it}^{\beta_i}} \tag{13}$$

(13) divided by “Index of Comprehensive S&T Progress”, the $TFP3$ not including the progress of S&T is:

$$TFP3_{it} = \frac{Y_{it}}{T_{it} L_{it}^{\alpha_i} K_{it}^{\beta_i}} \tag{14}$$

The contribution ΔT of growth rate of “Index of Comprehensive S&T Progress”, ΔI , to TFP2 from t_j to t_k is:

$$\Delta T = 1 - \frac{\text{Growth Rate of } TFP3}{\text{Growth Rate of } TFP2} \tag{15}$$

3 Empirical Research of Regional TFP of 2003 ~ 2011

3.1 Unit root test

With software of Eviews6.0 to test the stability of the panel data, the results are shown in Table 1.

Table 1 Results of Unit Root Test of Panel Data

		LLC	IPS	Fisher-ADF	Fisher-PP
Level	LnGDP	-0.52958(0.2982)	5.81307(1.0000)	9.01567(1.0000)	22.9536(1.0000)
	LnK	1.93618(0.9736)	6.58754(1.0000)	14.9710(1.0000)	48.8909(0.8871)
	LnL	-9.15507(0.0000)	1.30753(0.9045)	53.0397(0.7842)	96.0182(0.0036)
	T	-7.94894(0.0000)	-0.19680(0.4220)	69.3767(0.2507)	105.387(0.0005)
1st Difference	LnGDP	-21.0177(0.0000)	-8.64289(0.0000)	208.740(0.0000)	246.099(0.0000)
	LnK	-17.8577(0.0000)	-7.00685(0.0000)	179.520(0.0000)	284.674(0.0000)
	LnL	-5.00901(0.0000)	-2.44960(0.0072)	101.742(0.0011)	130.865(0.0000)
	T	-19.4846(0.0000)	-8.04062(0.0000)	193.331(0.0000)	247.793(0.0000)

From Table 2, all the level data of the variables were no stability based on 4 methods, but the 1st difference were stability at the 1% significant level, so the cointegration test can be done.

3.2 Cointegration test

Because of no stability of the variables, the Cointegration Test method proposed by Kao (1999) for the level and the 1st difference data of LnGDP, LnK, LnL and T of each region(as shown in Table 2).

Mean	2.962	0.074	2.865	0.071	0.067	0.014	40.90%		

According to formulas of 3.3 and 3.4, the value and growth rate of TFP, TFP2 and TFP3 from 2003 to 2011 of 31 regions were calculated, and the contribution ΔT of growth rate of “Index of Comprehensive S&T Progress”, ΔI , to TFP2 (as shown in Table 5).

6 Conclusions

“Index of Comprehensive S&T Progress”, surveyed through 34 indexes by the Development Planning Department of National Ministry of Science and Technology, had given the comprehensive, integrated to reflect the S&T progress situation of various areas, so not only did it influence the output elasticity and labor and capital, but also its growth rate had the important influences to TFP2. Therefore, in order to achieve steady growth in real GDP, especially in the condition of environment optimization, the comprehensive S&T progress should be paid great attention. Only in this way, can we fundamentally guarantee the scientific development of economy.

Index of Comprehensive S&T Progress influence Production Function. From analysis results in Table 6, the output elasticity of capital and labor calculated through method of Ordinary Least Square (OLS) and standardization with production function (12), joined Index of Comprehensive S&T Progress, were different from those with production function (7), and the standard output elasticity of capital with (12) was greater than that with (7) (exception of Hebei, Heilongjiang, Henan, Hubei, Gansu, Qinghai, Xinjiang), then changed the production function.

Growth Rate ΔT of Index of Comprehensive S&T Progress influence Growth Rate of TFP2. According to ΔT , 31 regions can be divided into the following four groups:

Regions of Contribution below 70%: Beijing, Tianjin, Shanghai, Jilin, Ningxia, Liaoning, Guangdong;

Regions of Contribution 70 to 80%: Shanxi1, Hainan, Shanxi2, Hunan, Tibet;

Regions of Contribution 80 to 90%: Sichuan, Guangxi, Jiangxi, Yunnan, Zhejiang, Fujian, Jiangsu, Guizhou, Anhui, Heilongjiang;

Regions of Contribution more than 90%: Inner Mongolia, Xinjiang, Hebei, Hubei, Shandong, Henan, Chongqing, Qinghai, Gansu.

Only contribution ΔT of Beijing and Tianjin were lower than the average 54.43%, which showed that the Comprehensive S&T Progress had played a very important role in promoting the development

of economic and social.

“Index of Comprehensive S&T Progress” had given the comprehensive, integrated to reflect the S&T progress situation of various areas, so not only did it influence the output elasticity and labor and capital, but also its growth rate had the important influences to TFP2. Therefore, in order to achieve steady growth in real GDP, especially in the condition of environment optimization, the comprehensive S&T progress should be paid great attention.

Development of regional economic depends on comprehensive S&T progress. There were the orders of the contribution ΔT and growth rate ΔI of 31 regions in table 6, this two orders of most regions were consistent, that is, the high the growth rate of Index of Comprehensive S&T Progress from 2003 to 2011, the high the contribution to TFP2; but the low contribution to TFP2, the high of the starting value of Index of Comprehensive S&T Progress, the high level of comprehensive S&T. So to narrow the gap between regions, it is necessary to close the gap between regional scientific and technological progress.

Chinese Cement Industry Transition, Status Quo, Policy Trend and Challenge

Guofei Ren, Kazuhiro Fukuyo

Graduate School of Innovation and Technology Management, Yamaguchi University,
Yamaguchi, Japan

(E-mail: s009wc@yamaguchi-u.ac.jp, fukuyo@yamaguchi-u.ac.jp)

Abstract: Chinese cement industry has been changed tremendously with economic development of China. This article reviews the history of Chinese cement industry and analyzes the current situation of cement industry from the political, environmental, and the other aspects by using the PEST analytic method. The challenges for the evolution of Chinese cement industries are also clarified.

Key words: Cement; Survey; Energy Conservation; Thermal energy; Environmental policy

1 Introduction

With the economic growth, China has become the “factory of the world”. Instead of that, however, it is now burdened with serious economic and environmental problems.

Source: Edited by Mineral Commodity Summaries USGS

Figure 1 Cement by Country Share of World

Cement production has expanded greatly. The world production of cement has increased from 1.6 billion tons in 2000 to 3.3 billion tons in 2010 (Figure 1). As the demand for cement in developing countries has increased, China’s share of world production has surged from 36% in 2000 to finally reach 54% in 2010, which accounts for more than half of production.

Reducing CO₂ from cement production and improving its energy efficiency are now nationwide propositions¹⁾. In order to improve energy policies in China, a plan to optimize the production system in the cement industry was implemented that has been targeting cement businesses from 2004 onwards to reorganize inefficient companies and weed out those that have kilns with low energy efficiency. According to these policies, the proportion of production using the New Suspension Preheater (NSP) has expanded to roughly 70%.

In 2006, Chinese government declared a policy to reduce the number of cement companies from 5000 to 2000. As the result of it, approximately 1500 production lines were closed by 2008, the volume of production was reduced by 52 million tons, and 1066 plants were removed²⁾.

These policies, however, have not been sufficient and there are still many natural resource and environmental problems in the industry. Chinese industry greatly affects the world’s resources and the global environment. Thus, it is necessary for China to receive support from developed countries, such as technology transfer regarding to energy and environmental management.

2 The Status Quo of Chinese Cement Industry

2.1 Cement classification and production methods

Cement consists of pulverized limestone, clay, silica, and iron raw materials. Cement clinker is

made by heating the above mentioned materials at high temperature. Portland cement can be obtained by the addition of plaster and pulverization.

Cement in Japan can broadly be divided into three types, “Portland cement”, “blended cement”, which is a combination of mixed materials of primarily Portland cement, and also “special cement”. The one mainly used in construction is Portland cement (Table 1, 2).

Table 1 Structure of Cement

Portland cement	=	Clinker	+	Plaster
Mixed cement	=	Clinker gypsum	+	Mixed material
Special cement

Table 2 Type of Cement

Portland cement	Ordinary Portland cement High-early-strength Portland cement Ultra-early-strength Portland cement Moderate heat Portland cement Low-heat Portland cement Sulfuric acid salt Portland cement White Portland cement
Mixed cement	Slag cement Fly ash cement Silica cement
Special cement	Alumina cement Ultrafine particle cement Cement solidifying material

Source: The Institute of Cement Association

According to the Chinese National Standard (GB), general cement is classified into as shown in Table 3. Special cement is classified according to its use and performance.

Table 3 Kind of Common Cement China

Type	Sign	Component		
		Clinker	Plaster SO ₃	Admixture
Portland cement type I	P. I	95~98%	<3.5%	—
Portland cement type II	P. II	90~97%	<3.5%	<5%
Ordinary Portland cement	P.O	80~92%	<3.5%	6~15%
Slag Portland cement	P.S	25~78%	<4%	20~70%
Pozzolana Portland cement	P.P	45~78%	<3.5%	20~50%

		Long wet kiln
		Retour kiln
		Suspension preheater kiln with Suspension Preheater (SP)
		New dry kiln outside cracking furnaces (NSP)
	Vertical kiln	Usually vertical kiln
		Machine vertical kiln

2.2 Cement manufacturing processes in China

Cement manufacturing can broadly be divided into five processes, such as (1) mining of raw materials, (2) blending and pulverization of raw materials, (3) firing, (4) finishing, and finally, (5) shipping (Figure 2).

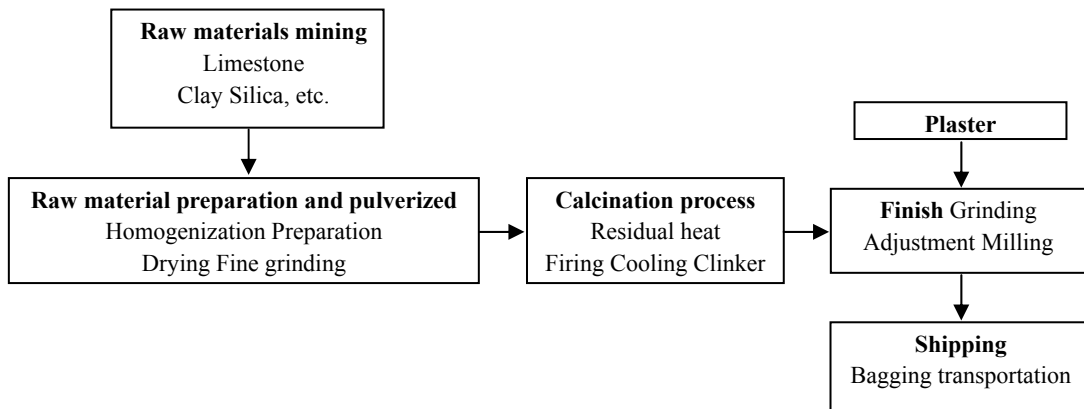

Figure 2 Cement Manufacturing Process Diagram

2.3 Changes in China’s cement industry

The cement industry has supported China’s socio-economic development through the supply of foundation materials for construction. Chinese cement industry has developed at very high speed over the approximately 63 years that have passed since the founding of the state of New China in 1949³⁾.

1949~1957	After the founding of recovery And Initial stage of development 1949: 34 companies, 1952: 2.86 million tons, 1957: 6.86 million tons, Imported from abroad: production line, 1957: The published standard cement
1958~1965	Great Leap Forward policy outcome And Economic adjustment stage 1958: 34% increase from the previous year, 1959: 27% increase from the previous year 1965: 16.34 million tons "Established one company large and medium-sized cement companies in each ministry properly The spread across the country 3.2 million tons stand kiln domestic
1966~1978	"Three line" construction And Stage of promoting "Cultural Revolution" 1970: Established rotary kiln standard 4.4×180m production line 1978: 65.23 million tons Cultural Revolution started, stagnation of economic activity, production of continuous decline Energy consumption and raw materials increase
1979~1984	Cement recovery of adjustment Announced the "About acceleration of cement industry development" Imports the new dry process production line from Japan and Romania NSP method is standard, I show how the development of the cement industry
1985~1995	The cement industry vigorous development stage Innovation to the new dry process kiln from the wet Cement companies listed, accelerate the development and expansion 1995: 593.99 million tons production capacity
1996~2000	Cement industry structure adjustment steps 1996: Change to modernization building materials industry 1998: To overproduction in the proliferation of small and medium-sized enterprises 2000: Lose the 3108 production line
2001~2011	New dry process high-speed development And Stage mergers and restructuring of industry 2002: Lose the 4894 line small kiln, 2007: Conducted mergers and reorganizations 2011: 2.1 billion tons

Figure 3 History of China Cement Industry

Source: Resized by each data

2.4 The current status of Chinese cement

According to the statistics on the cement industry by the National Bureau of Statistics of China, the volume of cement produced in 2012 increased by about 7% on 2011 to reach 2.21 billion tonnes (Figure 4).

Figure 4 Annual Production of Cement in China
Source: National Bureau of Statistics of China

Due to the effect of the real estate restraint policies, from the latter half of 2011, the growth rate of cement production decreased. Amid a swelling stock due the downturn in demand, plants began to either stop or cut back production. Reflecting the trend in supply and demand, the price of cement then dropped continuously up until the end of 2012⁴⁾ (Figure 5).

2.5 Chinese government’s policies

The Chinese government has continued to uphold “industrial consolidation” and “environmental protection” as two major themes in the 12th five-year plan of 2011. As to the “industrial consolidation”, the Chinese government promotes the consolidation of the cement companies and increases the market share of the ten largest cement manufacturers up to 35% by 2015. As to the “environmental protection”, the Chinese government facilitates the replacement of small-scale, old-fashioned, and inefficient plants with large-scale, state-of-the-art, and efficient ones, with the consolidation of the cement industries.

2.6 The leading Chinese cement companies

The leading private companies in the Chinese cement industry are located by region, because of the logistic problems of the procurement of raw materials and distribution of products. Thus, the leading companies locate in the economically-developed coastal regions. Table 6 shows the five largest cement companies for clinker production volume in 2012.

Table 6 The Five Largest Cement Clinker Company in China, 2012

	Corporate group name	Location (China)	Production volume (Billions of tons)	Growth rate (%)
1	CNBM	Northern, Central Southwest, South	2.95	50.51
2	CONCH	Eastern, Southern	1.50	12.00
3	SINOMA	North, Northwest	0.72	29.17
4	JIDO	Central, Northern	0.67	26.87
5	CRCHL	Southern	0.54	3.70

Source: network number midoro

2.7 The energy consumed by the cement industry

The energy-saving methods of the cement production are the Suspension Preheater (SP) method and the NSP method, and their utilization ratios in some countries are shown in Figure 6.

Figure 6 Penetration of SP • NSP (Production Volume and Capacity Based)

Table 7 shows the energy efficiency for cement production in China and the developed country (Japan).

Table 7 Advanced Level Compared to International Energy Use and Efficiency of China

	china	Advanced level international comparison
Cement energy consumption [kg ce (coal equivalent) / ton]	126	118 (Japan)

Figure 7 International Comparison of Cement Energy Efficiency

2.8 PEST analysis for China’s cement industry

The PEST analysis was applied to the Chinese cement industry. The results are shown in Table 9 and it describes that the opportunities for and barriers to the expansion of Chinese cement industry can coexist.

Table 8 Energy Consumption of Various Production

Production methods	Clinker heat consumption (kJ/kg)	Clinker coal Consumption (kg ce/t)	Relative value (%)
NSP • SP	3269	111	100
Reporu kiln	4096	140	126
Vertical kiln	4180	143	129
Long hollow drying kiln	5434	186	168
Long wet kiln	5852	200	180

2.9 China’s cement supply chain

Figure 8 shows the supply chain of Chinese cement industry. It consists mainly of the 3 parts such as purchasing model, manufacturing model, and sales model.

As manufacturing models, firstly, in the “single plant type”, the processes, purchase → clinker manufacture → milling → finishing → sales, and so on, are all completed at the same plant, the second is the “clinker + finishing plant type”, in which, while the purchase of raw materials and clinker

manufacture is completed in a suburban plant, milling → finishing → sales, and so on, is completed in an urban neighbourhood, and thirdly, the “finishing type” consists of just the processes clinker → milling → finishing → sales, and so on.

Figur 8 Industrial Chain of China Cement

Table 9 PEST analysis

Political factors	Due to policy, industry consolidation and reconstruction is accelerated
Economic factors	Expansion continues to infrastructure investment
Social factors	Promotion of energy efficiency
Technology factors	Birth and spread of new technologies

3 Problems Faced by Chinese Cement Industry

With the structural adjustment of the world’s coal industry due to restrictions on natural resources and energy, as well as the environment, the business is feeling pressure from such factors as the continuing high coal price, shortage of electrical power, a shortfall in rail transport capacity, and the high-level cost of fares.

Although the tendency of China’s cement industry to show a healthy increase is continuing, manufacturing technology is lagging when compared to developed countries, and a lack of investment in research and development means that the small capacity for innovation now presents a large obstacle (Table 10).

Persistent problems of imbalance exist: firstly, in the distribution of production; secondly, in the amount of fixed assets investments; and thirdly, in the distribution of total assets in cement.

Table10 The Comparative Cement Industry Technical

Item	Developed countries	China
Company size	World 60-120 million t Europe 70-80 million t Japan 260 million t	8 million t
Rate of production	France 3000 t / worker Germany 3000 t / worker Japan 15000 t / worker	District 160 t / worker National 280 t / worker
Kiln system Utilization rate	94%	89%
Clinker Heat consumption	World 2800kJ/kg Japan 2900kJ/kg	3900kJ/kg (Long kiln average)
NSP heat consumption	2888 kJ/kg Clinker	3555 kJ/kg Clinker
Clinker production Coal consumption	100kg Soot /t	175kg Soot/t
Cement manufacturing Power consumption	85kWh/t	115kWh/t
Clinker strength	70	60
Kiln dust emissions	25mg/ Nm ³	57mg/ Nm ³
Kiln exhaust gas NOx	200 mg/ Nm ³	500~1200 mg/ Nm ³
Kiln exhaust gas SO2	50mg/ Nm ³	200~400mg/ Nm ³

Source: China the Energy Statistics etc.

Eastern China, Southern China, Central China, and Northern China have become separate market leaders, respectively.

The top 10 companies in China only occupy 23% of China’s market share, whereas the top 10 companies in the world occupy nearly 50% of world’s market share, China’s poor industry-intensive

situation is thus evident.

The government has accelerated the transfer and weeding out of companies which do not conform to environmental policies, and has prohibited any new construction and expansion of cement companies that discharge large amounts of pollutants (Table 11).

Table 11 Chinese and Overseas Cement Plant Emission Standards Limit Comparison

Country	Dust (mg/Nm ³)		SO ₂ (mg/Nm ³)	NO _x (mg/Nm ³)
	Kiln	Chiller		
Germany	50	50	400	500
France	50	100	500	1200
U K	40	50	200	900
U S	70	40	750	900
Japan	50	50	750	500
China-1	100	100	400	800
China-2	150	150	800	1600
China-3	100	100	600	400

Source: China Cement Association

Note: China-1: Grade 2 Long kiln, China-2: Tertiary long kiln, China-3: Class vertical kiln.

The government has laid down goals for the cement industry to help build a recycling-oriented society that is energy and resource-saving. Business expansion is being constrained due to lack of policies and standards. Study on policy and financial support to the technological development and the installation of waste receiving and treatment facilities is underway.

4 Conclusion

The Chinese cement market is the largest one in the world, and is also an open up market. All the world's top cement companies have entered this market. In recent years, along with the strengthening of national policy on environmental protection and the improvement of production technique, the large Chinese cement companies have helped China cement industry to reach the global advanced standards gradually through both self-driven technology innovation and acquisition of international advanced technologies.

That said, when compared with international cement companies in the global cement market, China cement companies should further strengthen capabilities in the following areas including competitive edge, emerging- and resource-saving technologies, energy consumption, labor production, and utilization of resources and wastes. The following points help highlight the directions for further study and observation: (1) To consider the investment made by Japan's cement industry in China, (2) To consider the possibilities of transferring Japan's energy- and resource-saving technologies to China, (3) To consider the effects on the environmental protection if advanced technology were to be introduced to China, (4) To propose the required mechanisms to allow innovation in China's production.

A Study on the FDI's Influence on the Technological Innovation Ability in Wuhan of China

Wei Zhengfu

Huazhong University of Science and Technology, Wuhan, P.R.China, 430070

(E-mail: weizhengfuhust@126.com)

Abstract: Based on the analysis of the demonstration effect, competition effect, and training effect of technological innovation ability that FDI affects, the thesis uses cointegration analysis and error correction model, to analyze the relationship between FDI flow and technological innovation ability from 1990 to 2007 in Wuhan. The result shows that there is a long-term stable equilibrium relationship between FDI and technological innovation ability in Wuhan, however, the contribution of FDI flow to the granted patents is not obvious in the short run. There is a causal Granger causality between FDI flow of two-year lag and the number of patent authorization.

Key words: FDI; Technological innovation ability; Influence; Cointegration

1 Introduction

Technology innovation is the eternal subject of social survival and development, FDI plays an important role in promoting China's economic development since we join WTO. Many experts and scholars at home and abroad study the technological spillover effect and the influence of which to economic growth in the host country from different perspectives, the common view is for capital inflow countries and regions, FDI can not only provide capital to promote local economic growth, but also can produce the technology spillover effect, upgrade effect, trade effect, environmental effect and employment effect etc. Most economists emphasizes, FDI is one of the important indicators to explain China's sustained and rapid economic growth miracle and technological progress since more than 30 years. Generally speaking, the research on relationship between FDI and technological innovation ability, was explored by scholars at home and abroad the last 10 years. Although previous literature has involved it, which was mainly based on nationwide, lacking of regional research.

Wuhan began to take advantage of FDI since 1980s, up to 2007, actual utilization of foreign capital in Wuhan was 2250.05 million dollars, and foreign-invested enterprises in the proportion of the above-scale industrial added value reached 15.63%, the contribution rate of foreign investment total assets in the above-scale industrial enterprises is as high as 29.78%. Wuhan is the largest capital city in central China, which has advantages of good natural conditions, relatively good resource advantage, superior traffic communication position, relatively strong industrial base, intelligence-intensive science and education, and human resources, and so on, whose economic progress has been made. With the central China strategy, "two-oriented society" and Wuhan "1+8" city economic circle, the economic and social development in Wuhan will more and more depend on technology progress and innovation. Therefore, there is certain theory value and practical significance to take Wuhan as an example to make a research about FDI's influence on the technological innovation ability.

2 The Effect of FDI on Technological Innovation Ability

Generally, multinational enterprise is the carrier that FDI affects host country's technological innovation ability, FDI makes a far-reaching influence on technological innovation ability by operating multinational enterprise in host country. Multinational enterprises set up factories in host country in forms of Chinese-foreign joint venture, Chinese-foreign cooperation and wholly foreign-owned, which can offer technology to the host country subsidiary, and promote the technological innovation ability enhancement. At the same time, host country can make independent innovation by learning advanced technology from multinational enterprises, to promote technological innovation ability.

2.1 Demonstration - imitation effect

As there is technological gap between Multi-national Enterprises (short for "MNE") and the host country enterprises, the host country enterprises can enhance its technology and productivity levels by learning and imitate their behavior. This is also called the contagion effect. Foreign enterprises not only introduce new equipment and new products or new processing method into domestic market, but also brings dematerialization technique like product selection, sales strategy and management ideas etc. Under some circumstances, domestic companies can improve their productivity just by watching and

learning the neighboring foreign companies.

2.2 Competition effect

This effect occurred most among various manufacturers within the industry. Competition effect on the one hand, refers to MNE subsidiaries and the host country enterprises competing for the limited market resource, increasing the market competition, stimulating local manufacturers to use existing resources effectively, and promoting efficiency of indigenous technology; On the other hand, it means that in the industry with strong industrial barriers originally, due to the entry of MNE, monopolies has been eliminate to a certain extent, which can improve social welfare.

2.3 Training effect

We can confirm from the experience of developed countries, the competitive advantage of foreign capital is they can not be divorced from the human resource, fully materialized in equipment and technology. Therefore, the overseas investment projects' efficient operation of MNE, often combines with the development of local human resource. Such as local technical and management personnel work with experts who are dispatched by headquarter of MNE; Training local personnel; Local technical personnel take part in improvement work of technology, product and process and even R&D activities. Senior management personnel to learn and participate in the operation process of MNE's global network. It should be pointed out that, the researches of most scholars aimed at one of the channel of FDI's innovation ability in host country, without considering the relationship among the channels, lacking of systemic consideration. In addition, there is little theory research about the influence factors of technology spillover effect.

3 Cointegration Analyses of Data from 1990 to 2007 in Wuhan

3.1 The selection of indexes and data sources

When measuring technological innovation ability, the first problem involved is the index measuring technological innovation ability. Commonly used index of measuring the output efficiency of science and technology on the international are: patent, thesis of science and technology, high-tech products or technology-intensive products, technology trade, etc. Section 22 of the Patent Law provides that "patentable inventions and utility models, must possess novelty, inventiveness and usefulness." The article based on practical research, selecting the number of patents as an index to evaluate technological innovation ability of region in many of the scientific and technological output evaluation indexes.

In terms of FDI index, the article selects the index of actual utilization of FDI as FDI variable's index which was released by Wuhan Statistics Bureau. Since the actual utilization of FDI is priced in ten thousands of dollar, for convenience, the annual FDI raw data is converted to foreign direct investment in RMB price (RFDI) in this article, then taking the logarithm of RFDI values (LNRFDI). FDI flows and the number of patent authorization has been as the instead index finally, which is used to study the influence that FDI makes to innovation ability of region. It can be found that, LNRFDI and LNPTN change over time, therefore, it is a stationary time series, "spurious regression" phenomenon exists, the article used cointegration test of Granger-Johansen.

3.2 Model specification

The article made LNPTN as the explained variable, PNRFDI as the explanatory variable, the FDI and technological innovation ability model was set as follow:

$$LNPTN = \alpha + \beta LNRFDI + \xi \tag{1}$$

3.3 Model test and analysis

3.3.1 ADF test

Making ADF test to LNPTN, LNRFDI and DLNPTN、DLNFDI after first-order difference respectively, then draw the first-order difference time sequence diagram, the result is as follow:

Table 1 Stationary Test

Variable	Test types(I,T,L)	ADF test value	Critical Value	P Value	Results
LNPTN	(1,0,3)	0.107921	-2.666593*	0.9565	Nonstationary
LNRFDI	(1,T,5)	-2.167483	-3.297799*	0.4758	Nonstationary
DLNPTN	(0,0,0)	-3.124494	-2.717511***	0.004	Stationary
DLNRFDI	(0,0,3)	-2.312326	-1.96627**	0.0245	Stationary

Notes:Test types(I,T,L)shows respectively that whether there is constant term in ADF test (Intercept)、time trend item, and maximum lags.-2.717511*** means the value is critical value under the 1% significant level;-1.96627** means the value is critical value under the 5% significant level;-2.666593* means the value is critical value under the 10% significant level.

Although the time sequence of LNPTN and LNRFDI are nonstationary, however, their first-order differences are stationary. That means, time sequence of LNPTN and LNRFDI are integrated of order one (namely I (1) sequence). Therefore, the two times sequence may exist cointegration relationship, namely there is a long-time and stable relationship between LNPTN and LNRFDI.

3.3.2 Cointegration analysis

The article used E-G two-step method to make test to cointegration relationship between LNPTN and LNRFDI, the detail processes are as follow:

The first step: model estimation—Ordinary least squares method

Making regression to model (1) by EViews 6.0, the results are as follow:

$$LNPTN = -0.316421 + 0.522958***LNRFDI \quad (2)$$

$$t = (-0.169743) \quad (3.761860)$$

$$R^2 = 0.469348 \quad \bar{R}^2 = 0.436182 \quad F = 14.15159$$

According to above analysis, the ordinary least squares method that LNPTN conducted on LNRFDI, has got a significant elastic coefficient, on the whole, the model fits the sample data well, it indicates that an increase in FDI per unit, the number of patent authorization will increase 52.3%.

The second step: Unit root test of residual.

According to the estimated equation (2), we can get residual estimation:

$$U = LNPTN - 0.522958LNRFDI + 0.316421 \quad (3)$$

Using EViews 6.0 software, we can get residual diagram and residual sequence ADF test.

Table 2 Tset Result of Residual Stationary

Variable	Test Type(I,T,L)	ADF Test Value	Critical Value	P Value	Result
ξ	(0,0,2)	-3.335266	-2.717511***	0.0245	Stationary

Notes: “***” is the same meaning as 3.3-1.

Table 2 shows that ADF value is -3.335266, less than -2.717511 which is the critical value under the 1% significant level, thus residual sequence ξ reject the null hypothesis under the 1% significant level, the unit root is not exist, namely residual sequence ξ is integrated of order zero. According to the above results, we know that there is cointegration relationship between LNPTN and LNRFDI, and the cointegration vector quantity is (1, -0.522958, 0.316421). The test reflects on the flow of FDI and technological progress, we can find that in the long term, the elastic coefficient of RFDI to technological innovation ability is 0.522958, that means an increase in RFDI 1%, the number of patent authorization will increase 0.522958%. It indicates that the stimulating effect of FDI to technological innovation ability is not obvious.

3.3.3 Error correction model

According to the above analysis, the error correction model describing technological innovation ability makes long-time equilibrium adjustment with the change of FDI flow is:

$$\Delta LNPTN_t = \alpha + \beta * \Delta LNRFDI_t + \text{aecmt} - 1 + u_t \quad (4)$$

We select the four order lag variable at first, then eliminate some nonsignificant variables gradually, finally we get the error correction model after estimation as follow:

$$DLNPTN = 0.457621*** - 0.480393**DLNPTN(-2) - 0.544131***DLNPTN(-3) - 0.315339*DLNPTN(-4) - 0.235761*ecmt - 1 \quad (5)$$

$$R^2 = 0.885520 \quad \bar{R}^2 = 0.771039$$

We get follow conclusions from the above analysis: (1) There is a long-time dynamic equilibrium relationship between FDI flow and the number of patent authorization in Wuhan. (2) The number of patent authorization is influenced by itself and the change of FDI flow during a period of time. It can be seen from the equation (5) that growth change of two-year and three-year lag of numbers of patent authorization and FDI flow change of three-year lag whose influence to numbers of patent authorization are significant under the 5%, 1%, 10% significant level respectively. (3) The coefficient of error correction item ecm is negative, which conforms to the economic sense. If the previous period is more than this one, the economic system will produce a negative effect during this period, which can make the two variables of PTN and GDP achieve equilibrium in long run. On the contrary, if the previous period is less than this one, it will make a positive correction, all of the correction intensity are 0.235761, the correction coefficient indicates the degree of deviation from the long-term equilibrium relationship between the number of patent authorization and FDI flow short-term change is not great, namely the

equilibrium relationship between numbers of patent authorization and FDI flow makes little correction adjustment to unbalanced error current period.

3.3.4 Granger causality test

According to cointegration analysis, we know that there is a long-term equilibrium relationship between numbers of patent authorization of Wuhan and FDI flow. Making Granger causality test further, as Engle-Grange causality test only adapt to the stationary sequence, thus we use the data after first order difference; the result is shown in Table 3.

Table 3 Causality Test of FDI and Technological Innovation Ability

LAGs	DLNRFDI does not Granger Cause DLNPTN	DLNPTN does not Granger Cause DLNRFDI
1	1.59765(0.2284)	3.70663(0.0764)
2	7.57410(0.0099)	5.78409(0.0214)
3	30.9628(0.0002)	4.29580(0.0513)
4	1.57366(0.3356)	0.32338(0.8500)
5	1.45216(0.5556)	0.51146(0.7791)

Notes:The first sequence is lag phase, the second and third sequence is the null hypothesis of Grange causality test, In brackets is P value, out of brackets is F statistic.

The above table shows that when the lag period is two years and three years, under the 1% significant level, FDI flow constitutes the Grange reason of the number of patent authorization. As the same, under the 5% significant level, numbers of patent authorization of two-period lag constitutes the Grange reason of change of FDI flow. Under the 10% significant level, numbers of patent authorization of three-period lag constitutes the Grange reason of change of FDI flow.

4 Conclusions

4.1 Basic conclusion

From the cointegration analysis of time sequence data of the number of patent authorization in Wuhan and FDI flow from 1990 to 2007, we can find that there is a certain relationship between FDI flow and the number of patent authorization, although both of the increasing is nonstationary time sequence, they keep a long-term stable equilibrium relationship. In the short run, under the 5% significant level, each of the numbers of patent authorization of two-period lag and the FDI flow is the Grange reason; Under the 1% significant level, FDI flow of three-period lag is the Grange reason of numbers of patent authorization change; Under the 10% significant level, numbers of patent authorization of three-period lag is the Grange reason of FDI flow. Under other circumstances, there is not significant causal relationship between numbers of patent authorization and FDI flow, it shows that in short-term, the contribution of FDI flow to numbers of patent authorization is not obvious.

4.2 Countermeasures and suggestions

The economic development of Wuhan is a way of endogenous type development which relies on small and medium enterprises, private enterprises, the ability of introducing foreign capital is poor, which inhibiting the enhancement of local technological innovation ability. If a country or a region wants to possess real core competencies, and occupy the leading position in technological competition, getting rid of the dependence on external technology is necessary, it must rely on itself, enhance its technological innovation ability by independent research and development activities, namely carrying out independent innovation

4.2.1 Pay attention to the utilization quality of foreign capital

We should improve the foreign investment environment further, and expand the scope of drawing foreign capital, and improve the utilization level and quality of foreign capital. With the rising of central China, "two-oriented society" and Wuhan "1+8" city economic circle, the economic development model of Wuhan urgently need to change from endogenous type into endogenous growth combined with extroverted development coordinated development. Learning from the experience of the coastal provinces, taking active part in introducing foreign capital, and taking advantage of the advanced technology resource abroad, grasping the opportunity of international industrial division of labor and transfer, accepting and absorbing the transfer of foreign advanced manufacturing and R&D center. Therefore, Wuhan should strengthen the construction of infrastructure further, and in the basis of carrying on improving investment hard environment, striving to improve the soft environment for

investment. A foreign investment access system of unified, standard and open should be established, and the approval procedures for foreign investment should be simplified, and the work efficiency of examination and approval should be promoted, and we should improve the service to foreign investment enterprises, and improve the administrative environment further, in order to enhance the enthusiasm of foreign investment. Meanwhile, we should build a fair and effective market environment, to promote the transfer of technology from multinational enterprises to Wuhan, and increase the influence of technological innovation ability to Wuhan. Changing the way to use foreign capital from quantity to quality, and establishing a reasonable quality evaluation system of investment promotion, paying attention to the introduction of science and technology innovation investment projects, environmental friendly projects, and resource saving investment projects, to promote the introduction of advanced management experience and technology.

4.2.2 Encourage enterprises for independent innovation

The local enterprises in Wuhan on the basis of introduction, digestion and absorption, has achieved great success by imitating innovation to improve its technical level. However, the improvement of technology not only need external forces, but also need spontaneous source of technology, they can rely on itself to carry out independent innovation by independent research and development activities, and to get the core key technology, gain the competitive advantage. Though two ways of integrated innovation and introduction, digestion, absorption and re-innovation to promote independent innovation ability of enterprises and regions. In terms of strengthening the enterprise independent innovation ability, The most important is to enhance technological innovation power of enterprises, to make enterprises to actively become the innovative subject. However, independent innovation is an "accumulate steadily" process, with high investment, long cycle and high risk, which is hard to work. All of enterprises have strong dependence to the existing development model, and without powerful outside force or internal change, they will not change traditional path easily. From technology import to independent innovation, is the shunt of enterprises technical route. It must have strong external and internal cause to promote enterprises to decide to shunt. Generally speaking, external cause mainly comes from the external pressure and attraction of enterprises. For example, policy incentives from government, pressure coming from enterprise survival environment, the pressure of market competition, all of these will push enterprises to walk the road of innovation. Internal cause mainly comes from endogenous pursuit and passion, which shows in long-term strategy of company and entrepreneurship. Thus, in order to promote enterprises to become the innovative subject, government needs to and is making a series of encouraging policies, such as offering preferential policies for independent innovation enterprises, which fully shows the national determination of promoting enterprises to carry out independent innovation. But all of these are external because, if we can not mobilize intrinsic motivation of the enterprises and entrepreneurs, the government's call, the pressure of cadre examination may only make the enterprises "ordered innovation". it is difficult to believe that there is good effect to compete the innovation for "task assigned". Therefore, it is necessary for enterprises to formulate long-term strategy, and to strengthen culture and values of enterprises, keep strong entrepreneurial spirit, produce desire and passion for independent innovation endogenously, so as to promote the independent innovation power fundamentally.

4.2.3 Encourage R&D of foreign merchant to be localization

To promote FDI on technological innovative ability, we need strengthen the embeddedness of foreign capital enterprises in the host country, and encourage R&D of foreign merchant to be localization. MNE as the innovative subject can interact with domestic enterprises to improve the technology innovation. However, the achievement of this purpose is based on R&D of MNE to be localization. Nowadays, there are part of foreign investment enterprises which are value of some local governments' preferential policies, and set up factories in the mainland one after another, after enjoying the preferential, they will repeat the investment in another places, with little technology spillover to local enterprises, let alone have promoting effect on technology innovation of local enterprises. Therefore, if we hope to improve the positive promoting effect of FDI on technological innovation, it is necessary to make MNE take root in host country, only after foreign enterprises have strong embeddedness, will they take the advanced technology into production, and transfer which into the locality. Thus, Wuhan should improve policy measures to encourage foreign investment of high-tech industry and setting up R&D center, try to create foreign investment policy and market space which are suit for the development of high-tech entrepreneurial enterprises, promote R&D institution of MNE to be localization, and encourage MNE to set up R&D center in locality, and take part in developing patents. In addition, it is necessary to strengthen the foreign company integrated with the local industrial

enterprises, to help local enterprises finally achieve imitative innovation by introduction, digestion and absorption, and improve technical innovation level of local enterprises.

Regional Difference Regression Analysis of Contributions to GDP by Three Types of Patent

Li Yahong

University of St Andrews, St Andrews, Fife, Scotland, UK, KY16
(E-mail: YL496@st-andrews.ac.uk)

Abstract: Contribution to GDP by the output of patent is one of the most important indicators to measure the quality of regional economic growth. Using linear regression and ridge regression, this paper established functional model between the number of granted patent and regional GDP in four different regions. Research showed that in the region where industries are more prominent, its GDP will be more influenced by the output of patent and patent for utility models contributes most significantly to regional GDP. Based on the research results, this paper analyzed the corresponding reasons and put forward some suggestions in the perspectives of economic development stage, attributive character of patent, and regional economic structures.

Key words: Patent; GDP; A linear regression; Ridge Regression; Contribution

1 Introduction

Because of the unbalanced development of economy, the extensive growth mode becomes one of the major problems that the regional economic development in our country has to face in a long term. From the perspective of locations, resources and mechanism etc., scholars have had in-depth discussions about the internal causes of regional economic differences and brought up corresponding proposals and suggestions. In the era of knowledge economy, technological innovation has become the major driving force of promoting the regional economy. Patent, as an important manifestation of technological innovation, is not only one of the important indexes of comparing and measuring the status differences of regional technological innovation ability, scientific and technological level and marketization process^[1], but also an important indicator of revealing the regional differences and predicting the future differences of economic development.

Patent is legally-protected invention and greatest technical information sources-including 90%-95% of scientific and technical information in the world. Patent is not only an effective and convincing form of innovation output in a stage, but a basis of knowledge and technology in the next stage as well. In the transition from technology to benefit, despite of the problem of the knowledge transformation effectiveness, patent is still a generally accepted index and a credible measure both at home and abroad, from the perspective of using technological innovation indicating regional economy differences. The famous U.S. patent statistical analyst F Nalin had proved in 1994 that the number of scientific research patent had a close relationship with the economy of a country^[2]; Mark Croshby (2000) used patent to compare and analyze the innovation and development in countries like Australia and Canada^[3]. Domestic scholars Liu Hua (2002)^[4], Xu Zhuqing (2004)^[5], Fang Shu (2006)^[6], Zhang Jihong (2007)^[7], and Li Yemiao (2009)^[8] etc. made in-depth discussions about corresponding relationship between the number of patent and national or regional GDP. Looking through the works from experts and scholars, the research results are fruitful, most of which discussed patent as a whole, however in China, we divide patent into three types—inventions, utility models and designs, and those three types vary quite a lot in technological content, the contribution to and the influence on regional economy. Therefore the research of the correlation between patent classification and regional economy is a supplement of the current research. At the same time, it can deeper reveal the internal causes of the regional economic differences from the perspective of technological innovation, and further guide different regions to make corresponding measures and policies according to practical situations, which has important practical significance.

2 Relation Between Patent Licensing and Regional GDP

2.1 Regression analysis between the total number of granted patent and GDP

The objects of this paper were the 31 provinces and cities excluding Hong Kong, Macau and Taiwan, of which have been divided into the east, the central, the west and the northeast part. And the east part included Beijing, Tianjin, Hebei, Shanghai, Jiangsu, Zhejiang, Fujian, Shandong, Guangdong and Hainan; the central part included Shanxi, Anhui, Jiangxi, Henan, Hubei and Hunan; the west part

included Inner Mongolia, Guangxi, Chongqin, Guizhou, Yunnan, Tibet, Shanxi, Gansu, Qinghai, Ningxia and Sinkiang; the northeast part included Liaoning, Jilin and Heilongjiang. The statistics of GDP were from 2001-2010 Statistical Yearbooks by NBS and the information of patent was from 2001-2010 scientific statistical data by SIPO and NBS.

On the basis of the former research both at home and abroad, we presumed that the logarithms of the number of granted patent and the logarithms of regional GDP may have the following power function relation:

$$LnG = a + b LnP \tag{1}$$

Where: G=GDP, P=Patent, *a* was a constant coefficient, showing the part of GDP which is not influenced by the number of patent; according to the change of function relation, coefficient *b* can be expressed as $LnG/LnP + a/LnP$, whereby a/LnP was a constant, therefore *b* was the flexibility coefficient of GDP about LnP , meaning *b* can reflect the influence that each unit change of patent can exert on GDP—how much contribution each unit of patent can make to GDP^[9].

Using Formula (2) to do the correlation test between the logarithms of the number of granted patent in four major parts and the logarithms of regional GDP, the results showed: the correlation coefficient in the east part reached 0.931, 0.927 in the central part, 0.932 in the west part and 0.943 in the northeast. All the coefficients of correlation were above 0.8, meaning that the logarithms of GDP correlated significantly with the logarithms of the number of granted patent.

$$r_{xy} = \frac{\sum(X - \bar{X})(Y - \bar{Y})}{\sqrt{\sum(X - \bar{X})^2 \sum(Y - \bar{Y})^2}} = \frac{n \sum XY - \sum X \sum Y}{\sqrt{n \sum X^2 - (\sum X)^2} \sqrt{n \sum Y^2 - (\sum Y)^2}} \tag{2}$$

Using SPSS, the results of the regression between the logarithms of the number of granted patent in four major parts and the logarithms of regional GDP were shown as Table 1:

Table 1 Results of the Regression According to Regions

Region	R square	Constant a	LnP Coefficient b	Sig.
East	0.867	3.247	0.643	0.000
Central	0.859	2.954	0.723	0.000
West	0.868	3.047	0.676	0.000
Northeast	0.888	2.102	0.795	0.000

The results showed that the degree of fitting of LnP and LnG in those four parts are all above 0.8, meaning the model had extremely good fitting degree; P values of the significance testing were all 0.000 < 0.01, approved by significance testing.

2.2 Regression analysis between the number of classified granted patent and GDP

The above analysis has proved the power function relationship between the total number of granted patent and regional GDP, however, patent has been divided into inventions, utility models and designs, besides those three types vary quite a lot in technological content, and the contribution to GDP may differentiate as well. To further understand the root causes of the economic differences in those four regions, we have to further go into the relations between GDP and those three types of patent separately. Taking logarithm of three types of patent and GDP respectively and the results of correlation coefficient were shown as Table 2.

Table 2 Correlation Coefficient Between Three Types of Patent And Regional GDP

	R(LnG, LnI)	R(LnG, LnU)	R(LnG, LnD)	R(LnU, LnI)	R(LnD, LnI)	R(LnD, LnU)
East	0.796**	0.950**	0.870**	0.887**	0.738**	0.890**
Central	0.820**	0.919**	0.856**	0.847**	0.716**	0.886**
West	0.914**	0.934**	0.861**	0.932**	0.833**	0.894**
Northeast	0.922**	0.932**	0.774**	0.838**	0.795**	0.876**

Note: **. meant significantly related at confidence level of 0.01(both sides)

According to the power function relationship between the total number of granted patent and GDP, we can presume that the number of granted patent by types and GDP share the similar function relationship^{[2]-[9]}:

$$LnG = a + b LnI + c LnU + d LnD \tag{3}$$

Where: G=GDP, I=Invention, U=Utility model, D=Design

However, according to Chart2: the logarithms of GDP correlated significantly with the logarithms

of the number of classified granted patent, and the logarithms of those three types had high correlation with each other as well. Because of the multi-colinearity among the explanatory variables, Ordinary Least Squares cannot be used; therefore we used ridge regression to build the model. Ridge Regression Analysis is a nonlinear partial estimation method which is dedicated to deal with collinear data. It can better tolerate the morbidity of data than OLS, because the regression coefficients are acquired at the cost of lowering the precision by losing part of the information and giving up the unbiasedness of OLS. The R-squared value of the ridge regression is a little less than it of the normal regression, but the significance level is always obviously higher than the normal one. Using SPSS to implement the model, input syntactic command as followed:

INCLUDE 'D:\SPSS\Ridreg regression.sps'.

RIDGEGREG DEP=LnG/ENTER=LnI LnU LnD.

After running, we can see from the ridge trace graphs that when $k > 0.3$, the ridge parameter of each variable has been basically stable, therefore, we chose k between 0.0 and 0.3, step $INC=0.03$, and did the ridge regression again, getting the charts (omitted) and the figures as followed:

Figure 1 East Part

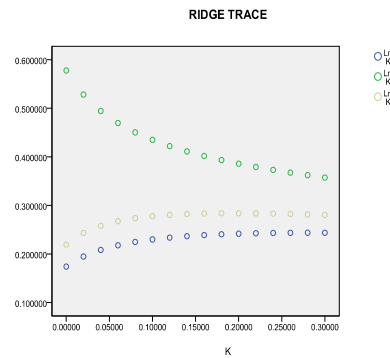

Figure 2 Central Part

Figure 3 West Part

Figure 4 Northeast Part

The ridge regression coefficient has already been stable while the ridge parameter k was between 0.00-0.03; with reference to the multiple coefficient of determination R^2 , we did the ridge regression again to the four regions respectively, getting summarized analysis as Table 3 showed.

Table 3 Coefficients of Multiple Linear Regression Model According to Regions

Region	K	R square	Constant a	LnI Coefficient b	LnU Coefficient c	LnD Coefficient d
East	0.16	0.883	4.177	0.070	0.361	0.180
Central	0.12	0.857	4.053	0.153	0.327	0.200
West	0.16	0.882	4.115	0.255	0.243	0.153
Northeast	0.18	0.926	3.813	0.298	0.369	0.012

The above chart showed that the degree of fitting between LnP and LnG in the four regions were all over 0.800, meaning the model had extremely good fitting degree; besides the significance had been approved by F-test.

3 Conclusion and Reasons

3.1 Main Conclusion

According to Chart2 and Chart3, we can conclude as followed:

Firstly, the output of patent is closely related to the regional economy. In the region where industries are more prominent, its economy will be more influenced by the output of patent. Comparing the four regions, we can know that the least influence that the output of patent exerted on regional economy was in the east part (constant coefficient was the largest), while the most was in the northeast part (constant coefficient was the least).

Secondly, contributions of patent for utility models to regional economy were the most manifest, then patent for inventions, and the least was patent for designs.

Thirdly, in the east part, among the three types of patent, patent for inventions made least contributions to regional economy; in the central part, contributions made by patent for designs were much greater than contributions it made in other three regions; in the west, the contributions to GDP from patent for inventions and utility models were similar; while in the northeast, patent for utility models contributed most to GDP, and the contributions from patent for inventions were obvious as well.

3.2 Reason Analysis

Combined the history of development with the current situation of regional economy, we concluded that the internal causes of the above situation were from the following three aspects.

Firstly, the macro-economy determines and influences the contributions that different types of patent can make to regional economy. Thanks to over 30 years of reform and opening up, China has entered a specific historical stage that has rapid economic development, further industrialization and sustainable transition of growth mode and industrial structure. During this stage, there has been a rapid increase in high and new technology industries, but the traditional industries aiming at scale and profit are still the economical backbone and the main body of our country (in 2011, the industrial added value of high and new technology industries in our country amounted to 10.49 billion, which only accounting for 12.4% of the added value of the second industry). The traditional industries are now of high maturity and most of the key technologies of the industries and fields have already become recognized as a standard. The profit of the companies mainly comes from the back-end of the industrial chain and the lack of technologies is mainly acquired by introducing and trading. This kind of mode leads to insufficient motivation for companies to pursue the patent for inventions, but encourages companies to develop large amounts of patent for utility models tailor-made for Chinese market in the process of introducing advanced foreign technologies. As a result, statistics showed that patent for utility models contributed a lot to the economy. In a meanwhile, another reason for the small contributions that patent for inventions made lies in the lack of the capability of independent innovation of high and new technology industries. Under the state policy of strongly promoting high and new technology industries, until 2011, our country have established 88 national high-tech zones and a huge number of provincial high-tech zones; however, from the overall development, there have been several common problems such as low level of high and new technologies, lack of self-owned innovation brands, and weak industrial cluster effect. Most of the high-and-new-technologies leading companies in China are either introduced enterprises or joint ventures, and those companies always aim to take over the Chinese market, build technological monopoly barriers and realize maximum benefits, which means very few of them would engage in independent research. As a result, high and new technology industries flourish, but the growth of patent for inventions is slow and its contributions to GDP are weak as well.

Secondly, the features differentiate among different patent. Patent for utility models means new practical technical proposals made for the shape, the construction or both of the products. It is called gizmo or petty patent as well, since its creative and technological level is relatively low, however, because of its low R&D cost and short production cycle, it can better adjust to the market-oriented economy, therefore, its practical value is high and its effect on economy is the most apparent. By contrast, patent for inventions has higher requirements on innovativeness of technologies, and also requires more amounts of resources and time; meanwhile, the market application will be more difficult, the marketization cycle will be longer and the economic benefits will have an obvious lagging effect owing to the high technological and creative level. Currently, small and medium-sized enterprises dominate the Chinese market (SME account for 99.8% of the total number of firms, and the output value account for about 60% of GDP). The low utilization and development capacity of SME about inventions is also a significant reason why patent for inventions has limited influence on the regional economy.

Thirdly, the economic structure varies from region to region. The east part is the early-developing

region. In 2010, its GDP reached 23.2 billion, among which 10.29 billion were from the tertiary industry, accounting for 58.3% of the state overall output value of tertiary industry. The modern service industry, which can be represented by finance, logistics, commerce and real estate, is very prosperous and the economic structure is high and light. Apart from manufacture-related service industries such as information service trades and creative industry which are highly associated with the output of patent, more consumer service industries and some manufacture-related service industries have a relatively weak correlation with the output of patent. Meanwhile, the east part of China owns the most private enterprises, and it is the biggest region for private economy which relies mainly on the introduction and utilization of the mature technologies. The ability and motivation of those companies for technological innovation is insufficient and their preference for patent is to purchase mature patent or the transformation of patent for utility models. SIPO did a research about the application and the authorization of private enterprises' patent during 1985-2005 and the data showed that during the 10 year period, the application quantity for patent from private enterprises made up 1/3 of the total amount. However, among the applications, only 13% is patent for inventions, less than 1/7, moreover, the granted patent for inventions only accounted for 3.1% of the total granted patent. The poor quality of patent directly affects its contributions to regional economy.

The overall economy in the central, west and the northeast part share the similar structure. In 2010, the proportions of the first, second and the third industries were 13:52:35, 13:50:37, 11:53:36, respectively; and in the second industries, industry accounted for 87%, 84%, 88% of, respectively. The statistics of patent showed that in the region where industries are more prominent, its economy will be more influenced by the output of patent. Therefore, the influence of patent on the regional economy in the northeast part was the greatest and meanwhile it is the most important heavy industrial base whose heavy industries take up over 80%. Besides most heavy industries are traditional industries whose technologies are already very mature, so patent for utility models played a major role in the development of economy in the northeast part. In the west part, the proportion of extractive industries such as mining is much higher than it is in the central and the northeast part, besides, the reliance of and the motivation for patent with regard to this kind of resource-based industry is insufficient, therefore, the influence of the granted patent on the regional economy in the west is less than it in the central.

4 Implications and Suggestions

Patent is an important manifestation of technological innovation, and the contributions to regional economy made by the output of patent reflect the quality and the structure of the growth of the regional economy. The data showed that the four regions in China all had huge space to adjust and improve. The east part has already taken the lead in economic strength at home, and the future economic growth should depend on the leading realization of technological capacity and the increase of output and utilization of patent for inventions, guiding the development mode of industries from OEM to ODM, OBM, and even to OSM. As for the northeast part, the traditional heavy industrial base, we should actively promote the integration of information and industrialization and seize the major strategic opportunity of readjusting the industrial structure. Moreover, we should achieve significant technological breakthroughs, strengthen the civilization of important scientific and technological achievements, and promote the great-leap-forward development of industrial economy by big projects like the new large aircraft, manned space flight and new energy development. The economic scale in the central and the west part is relatively small, and they mainly rely on the traditional industries. Therefore, we can rapidly increase the economic scale by vigorously promoting the R&D of patent for utility models. In the meanwhile, under the condition of fully considering the constraints of environment and resources, the transfer of such industries from the east to central regions should be undertaken. The central region should exploit its intensive science and education advantages to the full, make some breakthroughs in strategic emerging industries and modern service industries, and further strengthen and promote the economic contributions made by those three types of patent.

Abstract: In the “eleventh five-year plan”, Liuzhou put forward to Change “Liuzhou Manufacturing” into “Liuzhou creation”. As a pillar industry of Liuzhou, to improve the creativity of the auto industry is an extremely important part to realize “Liuzhou creation”. So this paper tries to establish a creativity evaluation index of the auto industry with the fuzzy synthesis method and provides some reference opinions for Liuzhou auto industry to improve its creativity.

Key words: Auto Industry; Creativity; The Fuzzy Synthesis Method

1 Introduction

Because of its profession characteristic, auto industry has become an important symbol of the development level of national manufacturing industry. There are 192 manufacturers in Liuzhou for automobile and engineering machinery parts and components and some large related enterprises, such as SGMW and Liuzhou machinery factory. Be stimulated by a series of positive policy, such as the national reductions of small displacement car purchase tax and the car preferential sold to the countryside, in the first half of 2009, the car industry output value reached 34.635 billion yuan, a year-on-year increase of 36.49%. The booming automobile industry contributes great to Liuzhou’s industrial production growth. The gross industrial output value completed by large-scale automobile manufacturing accounted for 43.16% of the total industrial output value of Liuzhou. Its contribution to the increase of the gross industrial output value reaches up to 117.33%, and pulls the gross industrial output value increase of 12.80%.

The development of Liuzhou’s automobile and automobile parts enterprise is one of the key factors of Liuzhou’s industrial development. Therefore, in Liuzhou’s “eleventh five-year plan” science and technology development program, automobile and engineering machinery parts and components technical r&d and industrialization projects are prioritized as one of Liuzhou’s ten key projects. If Liuzhou wants to transform “Liuzhou manufacturing” to “Liuzhou creation”, auto industry creativity ascension must be paid enough attention to. To evaluate the creativity of the car industry can find out the present problems during the process of automobile enterprises’ innovation, and enterprises can solve these problems by improving their creativity continuously. So the auto industry’s creativity assessment is very necessary.

2 The Foundation of the Creativity Index System in Liuzhou’s Automobile Industry

In order to make the evaluation index system can accurately and objectively reflect Liuzhou’s auto industry creative reality, this index system closely combines with actual situations of the development of China’s automobile industry of the time, follows the inherent law of the creativity development of domestic and overseas automobile industries. It can not only objectively reflect the true situation of automobile industry creativity, but also can reflect the related factors which influence the automobile industry creativity. All indicators determined are related to the auto industry, and each step of the evaluation indicator system construction is under the guidance of the system view and integrates all relevant factors. It can reflect the evolution trajectory of the automobile industry creativity systematically and comprehensively. And it avoids the repetition of the index assessment. Its each index evaluation content is relatively independent, and there aren’t include-relationship, overlapping and similar parts between each other.

* This paper is supported by Scientific research project of Guangxi department of education: “Industrial creative strategic planning research on Liuzhou” (Project Number: 200812LX306)

This paper evaluates the creativity of the automobile industry from following four aspects: the degree of innovation and investment; the ability of management and innovation; the construction of the innovation environment and the innovation output. It is shown in Figure 1 below:

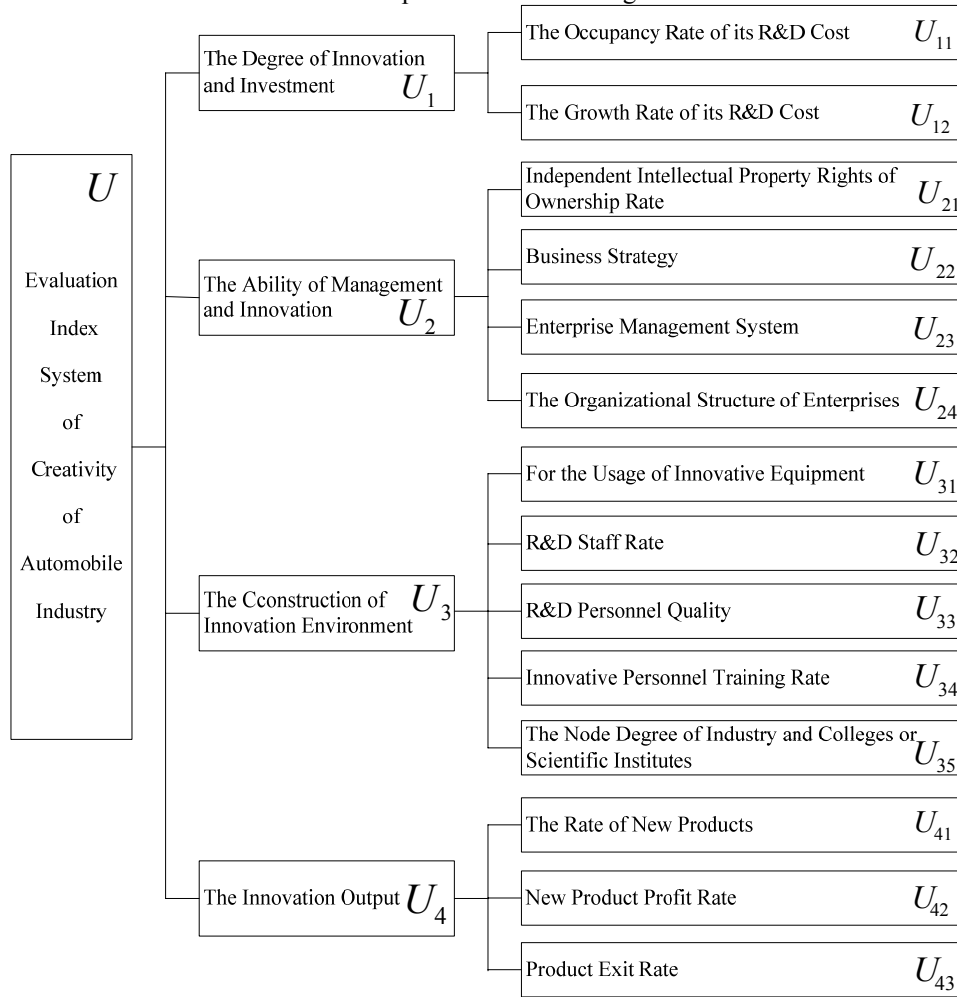

Figure 1 Evaluation Index System of Creativity of Automobile Industry Of Liuzhou

3 The Foundation of the Fuzzy Synthetic Evaluation Model

The evaluation indexes in table 1 contain qualitative and quantitative indicators, but not all of them can make accurate quantitative analysis, some indicators need to rely on the qualitative analysis and logical judgment made by evaluation subjects. To this kind of fuzzy phenomenon, we can use the theory and method of fuzzy mathematics to make fuzzy comprehensive evaluation. Fuzzy comprehensive evaluation model can make an overall evaluation to those uncertain rules, based on fuzzy mathematics theory and applying fuzzy transformation principle and the maximum membership degree principle, at the same time considerate and evaluate the various factors related to the evaluation object. The main steps are as follows:

3.1 Determining the Evaluation Factors and Evaluation Set

The evaluation set is divided into two levels. The first level is the general objective factors set U . It includes innovation investment degree U_1 , management innovation ability U_2 , innovation environment construction U_3 and innovation output U_4 these four primary indexes. The second level is the subtotals factor set. It includes 14 secondary indexes like the occupancy rate of its research and development cost U_{11} , the growth rate of its R&D cost U_{12} and so on.

The evaluation set is a kind of language description of all levels of evaluation index. It is a set of evaluation reviews. The evaluation reviews in this model can be divided into five grades. The specific comments collection is:

$$V = (V_1, V_2, V_3, V_4, V_5) = (\text{excellent, fine, so so, bad})$$

3.2 Weight Determining

This model adopts expert evaluation method and to be marked by experts with different disciplines background in view of the three main principles, and finally gains the weight.

(1)The innovation investment level, the management innovation ability, the innovation environment construction and the innovation output are all in the same important position in the creativity assessment of automobile industry. To despise any one of them will not provide the real auto industry’s creativity.

(2)In the innovation environment construction, scientific research innovation personnel’s quality is the most important. Only people’s active creativity can construct a suitable and innovative environment for scientific research to develop.

(3)How many innovation values a new product has and if it has some meaningful innovation or not, the most fundamental indicator is how much profit the new product will create.

According to the above three principles and integrated the expert opinion, this model weight is set as follows:

$$A = (0.25, 0.25, 0.25, 0.25) \quad A_1 = (0.6, 0.4) \quad A_2 = (0.25, 0.25, 0.25, 0.25) \\ A_3 = (0.1, 0.2, 0.3, 0.2, 0.2) \quad A_4 = (0.3, 0.4, 0.3)$$

3.3 The Determination of Fuzzy Judgment Matrix

Select some scientific research personnel and experts in auto enterprises to make up a jury to evaluate each single factor in the second level of the evaluation index system. In the construction of this model, we used a questionnaire survey. Based on the sorting and statistics to the results of the survey, we got a single factor fuzzy evaluation matrix.

$$R_1 = \begin{bmatrix} 0.5 & 0.4 & 0.1 & 0 \\ 0.3 & 0.4 & 0.2 & 0.1 \end{bmatrix} \quad R_3 = \begin{bmatrix} 0.2 & 0.4 & 0.3 & 0.1 \\ 0.2 & 0.5 & 0.2 & 0.1 \\ 0.2 & 0.5 & 0.2 & 0.1 \\ 0.2 & 0.2 & 0.4 & 0.2 \\ 0.2 & 0.3 & 0.4 & 0.1 \end{bmatrix} \\ R_2 = \begin{bmatrix} 0.2 & 0.3 & 0.4 & 0.1 \\ 0.3 & 0.4 & 0.2 & 0.1 \\ 0.2 & 0.3 & 0.3 & 0.2 \\ 0.1 & 0.3 & 0.4 & 0.2 \end{bmatrix} \quad R_4 = \begin{bmatrix} 0.2 & 0.3 & 0.4 & 0.1 \\ 0.2 & 0.3 & 0.4 & 0.1 \\ 0.2 & 0.3 & 0.3 & 0.2 \end{bmatrix}$$

From $A_1 = (0.6, 0.4)$, we can get the “innovation investment degree” evaluation vector:

$$B_1 = A_1 * R_1 = (0.42, 0.4, 0.14, 0.04)$$

From this we can see, the auto industry investment in innovation is in a good condition. To innovate, automobile industry spends a lot of money and the inputs on the innovation fund are increased year by year.

From $A_2 = (0.25, 0.25, 0.25, 0.25)$, “Management innovation” evaluation vector can be obtained.

$$B_2 = A_2 * R_2 = (0.2, 0.325, 0.325, 0.15)$$

From this we can see, management innovation ability of the auto industry is not good enough, there is further room for improvement. They should make efforts from the enterprise strategy, enterprise system, enterprise organization structure and independent intellectual property rights to better manage enterprises’ innovation ability.

From $A_3 = (0.1, 0.2, 0.3, 0.2, 0.2)$, “Environment construction innovation” evaluation vector can be obtained.

$$B_3 = A_3 * R_3 = (0.2, 0.39, 0.29, 0.12)$$

From this we can see, the construction of the innovation environment in automotive industry is good. This shows that the car companies already learned the importance of the introduction and the training to the scientific research personnel to improve the creativity of the automobile industry. In recent years, the automobile enterprises adopt corresponding measures to strengthen the combination of production, teaching and research to provide a good environment for the automotive industry’s innovation.

From $A_4 = (0.3, 0.4, 0.3)$, “Innovation output” evaluation vector can be obtained.

$$B_4 = A_4 * R_4 = (0.2, 0.3, 0.37, 0.13)$$

From this we can see, the innovation output of automotive industry is just so so, the enterprises need to speed up new product research and development, reduce the cost of new products, increase the profit of new products, and increase product exports.

At the same time,

$$R = \begin{bmatrix} B_1 \\ B_2 \\ B_3 \\ B_4 \end{bmatrix} = \begin{bmatrix} 0.42 & 0.4 & 0.14 & 0.04 \\ 0.2 & 0.325 & 0.325 & 0.15 \\ 0.2 & 0.39 & 0.29 & 0.12 \\ 0.2 & 0.3 & 0.37 & 0.13 \end{bmatrix}$$

$$\text{So, } B = A * R = (0.255, 0.35375, 0.28125, 0.085)$$

According to the maximum membership degree principle, we can see the creativity of Liuzhou's automobile industry is in a good condition. Compared with Guangzhou's automobile industry, the innovation output capacity of Liuzhou's automobile industry are relatively weak. It is closely related to their car types. Liuzhou should actively take measures to promote the class of their automotive vehicles to make a single car create more profits. Compared with Guangzhou, Liuzhou city still has some defect in the construction of innovative environment. It needs to optimize its innovation environment and vigorously introduce talents. While Liuzhou invests more in innovation, so that its automobile industry can obtain more resources and has more development potential.

4 Conclusion

In conclusion, the creativity of the auto industry is a connecting link between the preceding and the following in auto industry develop and construct. We can evaluation the Present Situation of the creativity of the auto industry throughout establish the evaluation index system and grasp the creativity status from the macroscopic, confirm improvements and corrective measures, so as to assurance the effectiveness of creativity input. What's more, specified the countermeasures in next development stage and made foundation of overstepping development.

This paper establish the evaluation index system of creativity of automobile industry of Liuzhou. Applicate the comprehensive evaluation method to evaluate the creativity, which make enterprise adopt the creativity strategy and continuously pursuing progress. Various aspects show that Liuzhou's automobile industry is booming. It is inseparable from the auto industry's good creativity. It also confirms the correctness of the data analysis in this paper.

What Lead to the Successful Mobile Phone Game? —Story of Birds Who Cannot Fly but They Have Enough Angriiness

Jaakko Iivonen, Yang Liu

Department of Production, University of Vaasa, PL 700, 65101 Vaasa, Finland

(Email: iivonenjaakko@gmail.com, yli@uva.fi)

Abstract: This article will consist of analyzing some factors which are the most important for the successful mobile phone game. There are going to be some common history of how mobile phone games are developed and how this whole game application business has started. Main focus in this article is based on analyzing and finding some key factors which are the most relevant for successful mobile phone game and how they can be designed. This article is not based on technical details of mobile phones and there is only some information which consists of a little bit of technical phrases. Angry Birds mobile phone game is excellent example of successful mobile game and it will be analyzed rather deeply in this article. Analyzing will not be based on only how to play game but whole Angry Birds phenomenon will be considered. Developments of mobile phone games have been very fast even though the first and nowadays classic mobile phone games (such as Snake) become in 1970s. Last year has been golden age for mobile phone game designers and this business area is still developing very fast. Rovio Entertainment is one of the winners so far. Since few years ago Rovio was close to bankruptcy and nowadays it is globally known entertainment media company. Rovio is behind the Angry Birds which is the most popular mobile phone game.

Key words: Angry Birds; Iphone application; Mobile phone game; Rovio Entertainment

1 Introduction

Designing successful mobile phone game may sound very simple task because smartphones does not offers very high technique to play the games. This is the tricky point when designers had to focus on create something especially which is at the same time very simple. Characters behind one of the most successful mobile phone game (Angry Birds) ever are birds whose are not able to fly or walk. This sounds as simple as it can ever be but how they can be so attractive and addictive to become global phenomena and spread to other business areas too.

This article is focused on analyzing why some of the mobile phone games are successful and some other does not have similar success. Aim of the article is to find if there are some elements which are repeated in successful games or are they just so well created. The first mobile phone games and even nowadays still many of them are not designed for smartphones. Normally games are designed to other game platforms such as personal computer or game consoles before and afterwards game designers are just copied or modified games to work in smartphones. One of the best known mobile phone games ever is the Snake which was released in Nokia 6110 –model. Nowadays the Snake is a classic mobile phone game but its history is similar as many other games too that it was firstly designed to be player by personal computer.

After the most of the mobile phones become smartphones also game designers realize that games are not so easy to modify from other platform to smartphones. Touch screens are one of the biggest reasons for this because control commands are so different when using touch screen comparing to buttons. Also at least some of the designers have realized that mobile phone games must be designed straight to smartphones if they want the game become successful. Other important element for mobile phone game is gamers profile and when and where those games are played. Normal mobile phone gamer is not willing to spend lots of time to learn how to play and they are not willing to watch tutorials before they can start playing the game. Mobile phones applications are used approximately less than one minute at the time so gamers are not willing to use lots of time for loading games. Also games cannot be based on some story because games concentration to play the game is not very high. Normally games are played when smartphone users are waiting something or they just have some extra time. Mobile phone games are not played similar as console games are when players focus is totally on game.

Angry Birds mobile phone is the one of the most popular game applications ever. Idea of game is very simple and player will achieve high results with a little bit of work when game will be addictive. Angry Birds is easy to learn and it can be played in very short-term. Nowadays Angry Birds is not anymore only successful mobile phone game, it is something bigger. It is phenomena spreading in many

other business areas also and only future will show us what kind of new things Angry Birds will be. Creators behind Angry Birds have told in many times that their dream is to be bigger than Disney. They want that Angry Birds is in future Disney 2.0. This is a huge dream and will it ever come true is something nobody knows at the moment but Angry Birds is already conquer so many areas and people hearts so why not.

2 Development of Mobile Phone Games

History of mobile games reaches over ten years, even there have been portable game devices since 1970s. Nokia released new 6110 - mobile phone in 1997. New mobile phone has also Snake-game, which is nowadays classic game and Nokia has estimated in year 2005 that there are about 350 million mobile phones which included Snake-game. Probably Snake is one of the most familiar and played mobile phone games. Idea of Snake is based same named video game which was released in 1970s and over the years there are published many different kind of versions of Snake. In fact Snake shows a very good which kind of mobile phone games are played and where those games are coming from. Usually mobile phone games are developed of games which are originally designed to be video games played by personal computer or video game console. Certain game cannot be said to mobile phone game only if it is possible to play game with your mobile phone. Game must take into consideration of special features and use of mobile phone. Real mobile phone game differs clearly of games which are designed to play only of portable game devices, such as Sony PSP and Nintendo DS. (Paavilainen, Korhonen & Saarenpää 2009.)

Original reason why Nokia added Snake into mobile phones was introduce mobile phones entertainment features and data transfer which based on infrared communication. Basic idea of Snake is very simple, player mission is to give directions to snake and try to eat snacks which makes snake to grow. Snake cannot be stopped so it must be steered all the time and if snake hits to wall or itself then game is over. After Snake there was installed to mobile phones lots of other classic games, like Tetris, Pong and Breakout. All the games were two colored since colorful screens to enter the markets. In 2003 Nokia released new mobile phone model (N-Gage), which include lots of gaming features. N-Gage reminded gaming devices from 1990s, like Atari Lynx and Sega Game Gear. N-Gage was not success in markets and afterwards is has been changed to be base for one of the Nokia's smartphone series. (Paavilainen et al. 2009.)

Current mobile games are mostly designed to mobile phones just take care of restrictions and they are not designed to take into consideration of mobile phones special features. Mainly game designers are fighting with mobile phones restrictions and they are not trying to develop mobile phones special features. Usually games have very modest audiovisual because devices have such a poor sound systems. Many of games which are designed in mid 2000s (like Tower Bloxx in 2005 and Nom in 2006) were based to hit one button in right time. Like it was earlier mentioned game is not a real mobile game it does not take into consideration of mobile phone special features. For example console video games are designed very accurate taking into consideration of consoles special features and these special features designated mainly which kind of games are designed to video game consoles. (Paavilainen et al. 2009.)

A real mobile game should consider the requirement of use mobile phone device and according to these it should also consider special features of device which are connectivity, socializing and the use of cultural. Nowadays mobile phones are all the time in network and this is reason why connectivity is the most clear special feature and it is also starting point for other special features as well. Even mobile phone devices are networked all the time, playing multiplayer games is not popular. Multiplayer games are very popular when games are played by personal computer or video game console. There is no mobile game which allows playing multiplayer games in real time, in other words synchronized games, so this is of course one reason why they are not so popular. Sociability is very important to mobile games and especially communication between players should be one of the starting points to design mobile game. (Paavilainen et al. 2009.)

Connectivity and socializing are supporting and essential related to each other. Mobile phone differs from so called static devices (like personal computer and video game console) clearly in culture of use. Mobile phones are always with user not depending on time or place. Normally using mobile phone is very short-term and the use of often interrupted. (Paavilainen et al. 2009.)

Average using continuously of one application is approximately one minute at a time, but anyway average using of mobile phone in a day is about one hour. Different kind of applications are used in different time of day, for example news applications are used mostly at morning, such as using game

application is the most active in evenings. Communication applications are used evenly during all the day time. (Böhmer, Hecht, Schöning, Krüger & Bauer 2011.)

Context of use mobile phones is posing challenges to game designer because in the beginning of designing they should consider many things, such as players cannot concentrate all the time to playing or playing games cannot cause too much distraction to other people whose are around the player. Playing mobile game may be interrupted by coming phone call and message. Communication is still principal use of mobile phones and it is not limited only to phone calls because communication possibilities with smartphones are versatile at which time game sessions might be very disjointed. (Paavilainen et al. 2009; Böhmer et al. 2011.)

The most restriction in smartphones is size of screen as this will affect what can be displayed in the game and game designer have to make a decision to focus on the action or the wider environment. Mobile games that are trying to put too much at once, the problem is that the player is not able to accurately detect what is going on in the game. For example in Splinter Cell –action game which is based on shooting scenes there are so much action and activities that the player is hard to detect from which direction the enemy shoots at him. (Duke & Westwater 2011.)

Using smartphones is based on touch screens and games which are especially designed to smartphones are using very accurate when player is using touch screen. In general, the problem occurs by the game controlling the touch screen when the mobile game is developed of game which was originally developed for the console game. This kind of situation usually game designer seek to emulate control system of console games and this leads to problems where controlling game with the touch screen is very hard and even it is foreign to user who has learn to use control command which is based on touch screen. Often sport games, like Madden NFL American football suffers from problems arise the fact that the control commands are attempting to move directly from one system to another. (Duke & Westwater 2011.)

Mobile environment is a limited factor in mobile games that game designer should keep in mind. Games played on smartphones are not suitable for those games that require several hours of gameplay. Mobile games are often played with intend to fulfill some short period of time, such as waiting to bus or train and those games that require more time are not suitable for mobile games. Angry Birds is a good example of successful mobile game, as it can be played in very short period of time and continuing play after interruption does not require any special actions. Smartphones is often played out in public places which are also likely to impact on what kind of games consumers are willing to play. (Duke & Westwater 2011.)

3 Secret of the Successful Mobile Phone Game

Demand for mobile phone games is very high at this time. Since the prevalence of smartphones, mobile game designers have developed the most curious and versatile mobile phone games. For consumers this is a great thing because consumers who are gaming enthusiast this offers possibility to try lots of different kinds of games. Unfortunately, the issue has another side also; consumers must wade through a jungle of games which is full of really bad games to find those few excellent mobile phone games. Some of the game designers are not able to figure out why some of mobile phone games are so popular with customers, so their self-designed mobile phone games proves to be only a waste of time and money. (Burton 2012.)

Burton (2012) concluded that there are a number of repetitive elements which the most successful mobile phone game includes. These elements are:

- simple game mechanics,
- a little bit of work should follow great results,
- game should proceed simply without deep tutorial or story and
- levels of game should be simply and short.

Simple game mechanics is emphasized even at that stage when you are looking at profile of mobile phone gamers. Major of mobile phone gamers are average mobile phone users. So this group is full of pretty ordinary consumers whose may not be playing personal computer games or console games at all. Ordinary mobile phone gamer play games its suits for him/her and playing can be ended very quickly, so these consumers does not explicitly arrange time for playing games, such as other platform gamers may be doing. For mobile phone gamers it is important that the game can be start as soon as they want to play and also ended when they are willing to and playing a game should not require any previous experience of playing games. Thus, to be successful game it is requiring simplicity and number of

commands must be minimized also. (Burton 2012.)

Playing mobile phone games should be easy to learn. It is one of the key factors for the successful mobile phone game. Smartphone users are not willing to spend time to learn how to play game. Correspondingly console game players are using lots of time to modify and customize settings, but such activities are not willing to do playing mobile phone games. Getting easily and fast started is one of the most important factors. Usually, the game is available in a free version (lite version), which should be easy to learn, simple and addictive game. If the game fails in one or several of these three factors, then the game is unlikely to be played again and the player will not be going to download full version of it, which normally is chargeable. Anyway consumers are not willing to either invest in a very large amount of money to chargeable games. (Duke & Westwater 2011.)

An interesting mobile phone game should offer great results with a little bit of work. Perfect example for this is the game Angry Birds. The player activates catapult by moving finger on the screen and then lifting finger on the screen will release the catapult. After effect is chaotic when there are lots of explosions, buildings collapse and birds will be released out of their cages. This satisfied players and will make them come back to playing game again. The most successful games, such as Angry Birds, Cut the Rope and Doodle Jump operates in a similar concept, there are very simple control commands and successful recipe is a simple tactic will lead to success, and that is not a coincidence. (Burton 2012; Duke & Westwater 2011.)

At the moment one of the most popular mobile phone games is called Tamago. Idea of this game is to download an egg on the smartphone screen which is to be broken by tapping the screen one million times. Next to the egg there is counter which counts every tap on and on every thousands tap will make a small crack to the egg. Tamago is considered to be very addictive game and some of the players feel this is good way to be less stressed. Some of players have already given up hope because there were nothing visible results. The simpler game may be difficult to develop.

The idea of mobile phone game concept may not be based on the complexity of the story or plot, such as it is in personal computer and console games which story is a meaningful factor. Mobile phone gamer wants to pass the level and after that player is able to end playing and come back afterwards and continue playing from the same spot. Idea of mobile phone game should be simple and possible plot may not have important role in terms of gameplay, as the player may easily ignore some important issues for the course of the game which may affect that passing a level is not possible anymore. (Burton 2012.)

Mobile phone games level should be concise and passing levels should not demand too long period of time. Game designers should take into consideration that player attention to the game is short-term, because there is lots of distraction when games are usually played, for example waiting the bus or train. This is reason why levels should be designed to be short enough to catch players' attention. If levels are too long and the player progression in the game is not going on, the player will easily get bored and will not come back to play anymore. In order to create user-friendly mobile phone game it should be easy to grasp and simple control commands. All in all behind the successful mobile phone game is simplicity of all related factors to a game. (Burton 2012; Duke & Westwater 2011.)

4 Rovio Entertainment Ltd and Angry Birds

Rovio Entertainment Ltd, better known as Rovio, is a Finnish company. It is established in 2003, when the company operated under the name Relude. In 2005 name was changed to Rovio Entertainment Ltd. Rovio is working in entertainment media business area and it is the well-known game design company. In 2009, Rovio was close to bankruptcy before they succeeded to develop well-known Angry Birds mobile phone game. Rovio was forced to downsize the number of employees from 50 to 12. Nowadays Rovio employs over 500. Rovio's headquarter is in Espoo, Finland; in addition Rovio has operation in Tampere also. The rest of world Rovio has operation in United States, China and Sweden. Rovio has three main persons who are the heart of the company. CEO is Mikael Hed and his cousin Niklas Hed is one of the co-founders. Peter Vesterbacka's official title is chief marketing officer, but he is the best known as the "Mighty Eagle". Rovio is now a world-wide company and employees represent more than 30 nationalities. (Rovio Entertainment 2013; Wikipedia 2013.)

Relude was established to contribute to success of the game King of The Cabbage World, which was developed by three students (Niklas Hed, Jarmo Väkeväinen and Kim Dikert) to mobile phone game contest, which was sponsored by Nokia and Hewlett Packard. After the contest Sumea company bought the game King of the Cabbage World and renamed it to be Mole War and the advertising it was

said to be the first mobile phone game than can be played in multiplayer mode. Before Angry Birds game Rovio (and Relude) published a total of 51 games. Some of the games were resold by millions to third party (such as Namco and EA). Rovio decided to create and design their own game, which original copyrights they will own. (Cheshire 2011; Magrigal 2011.)

Angry Birds is a random puzzle game where the aim is to fling birds using catapult towards a different kind of structure which are full of different blocks and some pigs. The aim is to hit directly to pigs or to structures so that they will collapse on top of pigs. The game idea is to destroy the pigs, and usually this requires destructing the structures around the pigs. The player has available a certain number of birds, which have different special abilities, such as the one birds is able to diffuse into a plurality of birds, a one birds may be used as bomb and one bird is able to use as rocket, and so on.

Rovio's problem was not to create and design good games, but company's the biggest problem was the marketing and distribution channels. Release of the first iPhone and thereby created App Store opened a new patch to reach consumers without that they had to negotiate with every mobile phone manufacturer separately. App Store opened the whole world, because with on single contact Rovio was able to reach worldwide distribution. Rovio realized that in iPhone platform environment there was very high competition, but if you succeed in that environment, then you are able to extend to other smartphone platform, personal computer and consoles as well. Rovio decided to focus on designing its own mobile phone game to iPhone platform and discard the other mobile phone platforms for a while. This plan was made long before idea of Angry Birds became. The aim was to conquer App Store, but before invasion to App Store they needed to analyze iPhone user profiles very accurate. They found that target group of iPhone users are all kind of persons. So they need to create and design mobile phone game that everyone can play it. Previous Rovio had focused mainly to design sci-fi and horror games, so this new idea differ lots of previous games. Rovio decided to change game designing criteria, in which case a new game should be extensible to other application platforms, but is should work like game which is designed to iPhone. Other factor was that game should be based on the physics, it should not include introduction section or tutorial, time to start and end game should be as short as possible to maximize satisfaction when game is played short period of time. The last factor was that there should be such icon, which will allow it differentiates in App Store. (Rovio Entertainment 2013; Cheshire 2011.)

In early 2009, Rovio's game design director Jaakko Iisalo introduced bird characters who did not have the legs and do not know how to fly, and they were looking very angry. Rovio's team began to wonder why the birds are so angry and even birds were very simple characters, they forced the team to think very much and they feel the characters to be somehow magical. Structure of the game and the characters evolved and changed a lot from the beginning to how consumers see them nowadays. The most significant changes during the development phase were that the birds initially responded to the colors of boxes and when the birds hit corresponding box it was crushed. Also the catapult which flings birds was added at the end of design project. Reason why there are pigs is that team needed to come up with the reason why the birds want to break down structures and idea for pigs green color appeared from news of swine flu. Green color reflects to a sick pig. Still team had to develop a story why the birds are so angry to the pigs whose seem to be very docile and wise; result for the birds' anger is that the pigs have stolen their eggs. (Cheshire 2011.)

Angry Birds was released in App Store on December 2009. The first few months was not success at all, Angry Birds was flop in the most profitable App Store markets. Rovio's strategy was not to achieve exponential invasion to the App Store, but the strategy was more of like a guerilla war to achieve better position first in smaller App Store markets. Rovio was realized that large markets would be difficult to break in, but success in the smaller countries markets did not needed to have large amounts of purchases. For example, the number one place on the Finnish App Store market needed only few hundreds purchases. The same situation was also in Sweden, Greece and Denmark. Nowadays, the UK and U.S. App Store markets are about 90 per cent of Rovio's total markets, but to get first purchase from these App Store it took to get about 30 000 to 40 000 downloads before from smaller markets. This amount of downloads is not particularly large, but it is still about four times what the average application normally sells. Rovio also used a help of self-publisher company (Chillingo), who had managed to take a number of applications in the App Store and Chillingo also had a good relationship with Apple. (Cheshire 2011.)

In February 2010, Apple approved the Angry Birds to UK App Stores front page in week of the game list. At the same time Rovio made a promotional video of the Angry Birds to Youtube-video service. This video was the second in history which was made of Iphone game. Today, this video has more than 17 million views. Rovio also added 42 levels to Angry Birds and released the first free

version of the game. These all were released within three days and after advertising Angry Birds rose from 600th to the first place in UK App Store, and in April Angry Birds achieved the first place in the United States. (Cheshire 2011.)

After the first Angry Birds release it took a few months that the game had become an international phenomenon, and today it is the all-time most popular chargeable application. Rovio has released eight successful games so far, they are; Angry Birds, Angry Birds Seasons, Angry Birds Rio, Angry Birds Space, Angry Birds Friends, Amazing Alex, Bad Piggies and Angry Birds Star Wars. Angry Birds success in mobile phone games has been expanding rapidly to other business areas also, such as entertainment, publishing and licensing activities. Angry Birds has become a beloved international brand. (Rovio Entertainment 2013; Cheshire 2011.) It is interesting to see how far birds can go without legs and ability to fly. Angry Birds have shown to whole world that with certain angry everyone is able to achieve dreams.

5 Conclusions

There are few main factors which reflect success or failure of mobile phone game. They all are as important and they cannot be ordered anyway. There they are just mentioned in random order. Story behind the mobile phone game should not have main or even essential role because mobile phone gamers do not have enough concentration to follow up stories or tutorials. This element has also other meaningful point because mobile phone game need to be easily ready to play; there not supposed to be long loading times and every extra tutorial will slow down to start playing. Game mechanics have to be very easy to learn. Gamers are not willing to spend their time to learn how to play game; they just want to start playing when they have time to do it. Easy game mechanics should also include easy control commands. Nowadays mobile phone games are played on smartphones and controlling games with touch screens offers many possibilities but also some restrictions. Control commands should be quite simply because as it was earlier mentioned gamers concentration is not totally focused playing games and normally gamers are doing something else at the same time. One key element to successful mobile phone game is to offer great results with a little bit of work. This element represents the main idea of mobile phone game because successful game is addictive and which is more addictive than gamer make some commands on screen and afterwards there are lots of actions on screen. Maybe the most important key element to successful game is that it should be simply and short in every way. Gamers are willing to play the game for a short-term and the must also allow some disruptions for example incoming call and incoming SMS message and the game should be easily to continue after some disruptions.

The history of mobile phone games is very short and they are at the beginning of their development. At the moment gamers are willing to play very simply games which offers just fun for short-term. Technology and innovations are developing very fast on smartphones so it may be totally different story after few years. Smartphones screen sizes are one of the biggest restrictions to develop wider stories but this may be changed very rapidly because bigger sizes screescreen seems to be trend at the moment in the most popular smartphones models, such as Samsung Galaxy S4 (screen size 5" versus Samsung Galaxy S3 screen size 4,8") which will be released soon. Nowadays consumers have lots of different kind of entertainment devices like smartphones, personal computers, tablets and game consoles. There may not even be demand to more developed games to mobile phones because consumers are willing to fill out extra times (for example waiting friends or bus) with playing mobile phone games. Then games are not needed to be complex and versatile but they need to be entertaining and addictive because it is so easy to download new game if gamer is not satisfied with it. Angry Birds have become phenomenon and there have been continuum when gamers have been able to download more levels or new game without need to find totally new game. Angry Birds have also spread to other business areas too so it is real phenomena and it is still conquering new business areas all the time. Creators behind the Angry Birds have dream to become like Disney 2.0. It is a huge dream and there are lots of people who are thinking they have to be totally out of mind. Anyhow they have succeeded so far with Birds who are not able to fly or walk but they have had enough angriness to become phenomena. Within next year there are going to be more Angry Birds moving around us or there are going to be something else which will entertain us.

Abstract: This paper takes the opto-electronic information industry cluster in East Lake High-tech Zone as the research object. Firstly, we depicted the development status quo of electronic information industry cluster. Based on which, we then analyzed the problems in the opto-electronic information industry cluster including lack of coordination and linkage mechanism, short in prospective studies, poor stability of the backbone R&D personnel, and lack of benign soft environment which is essential for the development of industrial cluster. Finally, we put forward countermeasures and suggestions from perspectives of building basic research and development platform, improving the industry chain of opto-electronic technological innovation, stabilizing the backbone of R&D personnel, and establishing supermarket platform of professional service.

Key words: East Lake High-tech Development Zone; Opto-electronic information industry; Industrial cluster; Industrial chain ; Independent innovation capability

1 Introduction

The industrial cluster is a new trend of the industry development to adapt to the global economic and increasing competition, and an organization of the industry space which is to create their own relative competitive advantages. The other organizations are difficultly compared to the industrial cluster which has a group of competitive advantages and economies of scale. It is of great significance to research the industrial cluster for the rationalization of the economical layout, the optimization of resource allocation, forming the competitiveness of regional economic. Since the 1980s, the theories of industrial cluster flourish, causing the widespread concern in theoretical circles at home and abroad. Based on the high-tech park development strategies of industrial cluster, many countries and regions made high-tech parks become a new growth point of economic development, which highlights the positive effect of high-tech parks in the regional economy.

Based on the opto-electronic Information Industry in Wuhan East Lake High-tech Development Zone, the “Wuhan·Optics Valley of China” is the first national opto-electronic Information Industry base approved by the Ministry of Science and the National Development and Reform Commission in 2001. As one of the leading industries in Wuhan East Lake High-tech Development Zone, the opto-electronic Information Industry has formed an industrial cluster of specialization and collaboration including the optical communication, laser, information networking, opto-electronic products, and so on after several years of construction and development, which created the conditions to form an industrial chain that the upper, middle and downstream are interrelated. But the development of opto-electronic Information Industry still exist some difficulties. Selecting the opto-electronic Information Industry Cluster in Wuhan East Lake High-tech Development Zone as a case, the paper analyses the problems of its development in-depth and proposes some corresponding countermeasures and suggestions.

2 The Status of Opto-Electronic Information Industry Cluster in Wuhan East Lake High-Tech Development Zone

The industrial cluster refers to an organic system on a specific area forming by some interrelated (complementary or competing) enterprises and institutions concentrating in a certain geographical area, which has characteristics like the structural integrity of the upper, middle and downstream (from raw material supply to distribution channels or users), a sound industrial system of peripheral supporting, flexibility and so on. The cluster includes a number of interrelated industries and other entities which

* This paper is supported by Humanity and Social Science Project from Department of Education of Hubei Province in 2013 “Research on Development Strategy of Opto-electronic Information in Wuhan East Lake High-tech Zone (Item Number: 13g569)”.

play an important role on competition. Therefore, the enterprises in the clusters establish a close relationship which is both competitive and cooperated through the specialization and collaboration. The clusters also include some corresponding supporting mechanisms that provide ancillary services such as the local government, industrial associations, financial services and training institutions, etc. So, the clusters are a kind of soft production complexes and represent the regional core competitiveness. Since the Wuhan East Lake High-tech Development Zone was approved as a “National Opto-electronic Information Industry Base” in 2001, it has achieved remarkable success to develop the opto-electronic information industry cluster replying on the national and local support, the traditional opto-electronic information industry base in the region and the regional abundant resources of technology and education.

Table 1 Main Economic Indicators of East Lake High-Tech Zone Opto-electronic Information Industry

Indicators	2011	2009
General Income	145000 million	83562 million
The Average Annual Growth Rate	30%	30%
Domestic Market Share	More than 50%	50%
The Number of Enterprises	About 1000	828
Research and Development Institutions	700	454
Employees	200 thousand	95474

(Data source: According to the network data and the statistical yearbook of Wuhan East Lake High-tech Zone arrangement)

2.1 Opto-electronic Information Industry clustering within the region distinctive characteristics

Up to 2011, opto-electronic Information Industry reached 145 billion yuan of total revenue in Wuhan East Lake High-tech Development Zone, the average annual growth rate of over 30% in the past five years, its fastest growth compared with other industries, it has been among the world-class industry clusters. Optical fiber cable, optical devices, lasers and other products share of more than 50% in the domestic market. In which, the Production scale of fiber-optic cable is the world's first, formed a complete industrial from rods, drawing to cabling, domestic market share of over 66%, international market share of 25%. East Lake High-tech Development Zone is China's largest production base of optical devices research and development and laser industry base, optical devices products in the domestic market share of 60%, international market share reached 12%. Laser and other related products in the domestic market share of over 50% for 11 consecutive years. At the same time, in the opto-electronic Information Industry, the number of enterprises above designated size increased year by year, by the end of 2012 already exceeded more than a thousand. In which, Laborers technology, Yangtze Optical Fiber, Tianyu Information has been identified as a national innovation-oriented enterprises, FiberHome selected the first batch of national technology innovation demonstration enterprise. In addition, Consumer electronics, optical display, semiconductor lighting, photovoltaic solar energy industry is accelerating the development. Geo-spatial information, networking, smart grid, cloud computing and other emerging industries achieved initial success. The scale of software and service outsourcing industry rapidly expand, digital creative industry is booming. Huawei, ZTE, Lenovo Group, Deutsche Telekom, France Telecom, Wuhan Tianma and other famous enterprises settled in Optical Valley Technology Industrial Park. Opto-electronic Information Industry has shown rapid development momentum in Wuhan East Lake High-tech Development Zone.

2.2 Regional innovative resources provide effective intelligence support to the development of clusters

“Wuhan-Optics Valley of China” is a national and provincial key projects, planning area of 224 square kilometers, approximately 90 square kilometers have been built, gathering 42 colleges and universities, 24 national key laboratories, engineering technology centers, enterprise technology center, more than 700 technology development institutions, more than 200,000 professional and technical personnel and more than 70 million college students, 51 academicians, in which 10 academicians are leader of opto-electronic Information Industry. Up to 2013, Wuhan East Lake High-tech Development Zone has introduced and nurtured 431 high talents(including Hubei Hundred, national Thousand Talents Program, East Lake 3551 Talents Scheme), the number of Dr. is 4294, talents of opto-electronic Information Industry proportion accounted for one third. Opto-electronic Information technology is based on cutting-edge knowledge, the universities and research institutions just to be able to provide a

high level knowledge-based talents and high-level management talent to the opto-electronic Information Industry. "Wuhan-Optics Valley of China", relying on universities and research institutions to provide a strong talent and technology advantages, is second only to Beijing Zhongguancun and Shanghai High-tech Industrial Development Zone, China's third largest intelligence-intensive areas.

2.3 Industry cluster network system based on innovation network has been initially formed

As of 2012, East Lake High-tech Zone has 20 photoelectron information incubator industries, and being the representation of them are Wuhan East Lake New Technology Venture Center, Wuhan laborers technology business incubator and Wuhan Students Pioneer Park. The total hatching area are 1,624,000 square meters, and more than 700 enterprises are in incubation. The degree of specialization is higher within the region, and the core enterprises have a stronger driven effect. The products cover almost all of the photoelectron field and it forms the leading enterprises such as Fiberhome technology group, Yangtze optical fiber and cable company, Chinese science and technology, Yangtze River communication and Roton electronic. Other SMEs are complement to the industrial cluster. These enterprises not only compete with each other, but also promote the mutual development. What's more, due to the technology spillovers and the flow of talent and production coordination, these enterprises promote the development of related industries, and jointly create industrial clusters brand.

3 The Problems of Opto-Electronic Information Industry Cluster in East Lake High-Tech Zone

3.1 Enterprises in the cluster has not yet formed a complete industrial chain labor-division system, and are lack of coordination linkage mechanism

In addition to a small part of large cluster photoelectron enterprises, most SMEs can only be regarded as "assembly plants". A large number of electronic devices and integrated circuits are imported from abroad. Enterprises in the cluster lack the necessary coordination linkage mechanism, including the connection of product supply and demand mechanism, the collaboration of research and development mechanisms, strategic alliances, etc. In order to obtain profits, the large companies try to suppress the price of supporting parts which SMEs provide. Without any cooperative support, the SMEs has no corresponding increase in technology and management. Similarly, the international manufacturers also want to profit through lower prices way, rarely cooperating with companies to develop products within the cluster. In addition, the enterprises within the cluster have no real specialization. With the coordination of industrial chain being poor, the enterprises has not yet formed the mutual recognition of the cooperative system which is based on common cultural background. Due to the low business relatively, enterprises in the cluster are lack of technical cooperation and exchanges, and the efficiency of cooperation of industrial cluster reduce seriously.

3.2 Being lack of prospective studies, most enterprises are still in imitative innovation

The R&D capability of Wuhan photoelectron information industry cluster exists defectiveness. Very few enterprises have advanced technology. Only in the Yangtze, Fiber home technology and several big laser enterprises have advanced technology in optical communication, optical fiber and cable and optical devices. But they only keep pace of the advanced foreign technology. There is no advantage in innovation and R&D. Investigation shows that more than 80% of the enterprises in the cluster are absorbed in innovation results, rather than the innovation process itself. Not to mention the prospect, the enterprises have a serious shortage of independent innovation ability. Prospective studies are mostly pre-competitive basic research, generic technology research and the product innovation for future technical precipitation. It usually forms the new technical standards. If enterprises want to make achievements in technological innovation, firstly they should measure whether the prospective study of their own businesses meet the future market. Only do the enterprises' research is based on market development, they can lead the market. At present, the independent intellectual property rights of enterprises in the cluster is extremely insufficient. The core technology is shortage and the key technology is controlled by others. The overall level is not optimistic.

3.3 The stability of opto-electronic information industry's R&D team backbone talents is poorer

The stability of opto-electronic Information Industry's developing R&D team backbone talents is poorer. On one hand, the "internal brain drain" phenomenon of the opto-electronic Information Industry's R&D team backbone talents is serious. For the opto-electronic Information Industry has the characteristics of big investment and long cycle, and the fact that wuhan has rich human resources, most of the global important opto-electronic information companies set up R&D center in wuhan. But wuhan does not have independent intellectual property rights, so as to the R&D dominant position was

dominated by others, leading to a large number of "internal brain drain" phenomenon. A lot of excellent R&D backbone talents' and team's innovation ability was solidified in the existing R&D system framework of multinational enterprises, so they can't form the atmosphere for local enterprise to jointly overcome the difficult. On the other hand, the domestic enterprises lack of first line R&D talents. In recent years, along with the return of the returned oversea Chinese talent and team, the gap of R&D leading talents in domestic opto-electronic Information Industry is not effectively filled yet. Enterprises in the cluster generally show that many "sea turtles" choose the university scientific research institution or self-employment, but the number of who choosing the first line enterprise in domestic industries is not that much. In addition, despite the industrial park of East Lake High-tech Development Zone having a more perfect hardware supporting measures and relatively high quality human resource base, the attractive is also slightly obviously insufficient when compared to the investment attraction condition and the rich treatment for the foreign capital enterprise in Beijing, Shanghai and other places. According to the survey, if there is a better development space and a higher salary, more than forty percent of the team backbone R&D talents will choose outflow. Therefore, the quality and quantity of the domestic enterprise backbone R&D talent and R&D team are in the condition of slow growth.

3.4 The soft environment needed of industrial cluster's development is missing

According to the survey, some respondents said that the leading talents who want to establish a business with in Hubei province, not only do the research or start a company, but also do something in the fire control, environmental assessment, water, electricity, communications department is closely related and so on. For the relatively insufficient government professional service platform, the leading talents especially those from the colleges and the research institute was tired by the administrative affairs. It is essential for the government to provide training, coaching and mentoring for the leading talents, including the product approval deadline, industry listed process consulting, industry norms, administrative examination and approval, the investment and financing, etc. All the problems are caused by the absence of government function in East Lake High-tech Development Zone.

4 The Countermeasures and Suggestions for Promoting the Development of Opto-Electronic Information Industry in East Lake High-Tech Development Zone

4.1 Building basic development platform in opto-electronic information industry

The government set up basic development platform based on the industry chain or industrial cluster in order to effectively integrate the same or similar industry's science and technology resources. So it can share the scientific data and literature of science and technology, provide professional technology and technology incubation services etc, avoid inter-industry bulk type and segmentation development model, strengthen the transverse connection and exchange mechanism between enterprises by opening the instrument equipment and research base. Moreover, it can inject vigor for the enterprise, reduce the cost, increase the appeal for R&D talents, and then realize the purpose of driving talent gathered by industrial development.

4.2 Valuing the exploitation of advanced technology and perfecting the innovation industrial chain of opto-electronic technology

Wuhan opto-electronic industrial cluster should base on leading and special industry such as Optical fiber and cable, photoelectric device, laser equipment to form a tech-innovation industrial chain which is inter-pervasion, inter-dependent and upstream and downstream complementary, making industrial cluster more sizable and stronger. They should build local networks with collaboration to arrange project according to the formation of industry cluster, and attach great importance to the union, also pay attention to the cooperation of big, small and medium-sized enterprises, division of labor based on specialization and the well-equipped website system. Foster a technology environment, financial environment, logistics environment and humanities environment within the group according to allocation of resources in the market, shaping the mechanism of mutual coordination, cooperation and division of labor, fulfilling the role of the leading enterprises such as Fire Science & Technology, HUST Science & Technology, speeding up the development of cutting-edge technology, and gaining more patents, breakthrough of technology and industry.

4.3 Designing attractive salary system and execution system to stay the cores of research and development personnel

First, implement the plan of holding stock shares of core developers, getting personnel and enterprise development prospects together, sharing the benefits and taking the same risks. Second, allocating income due to scientific and technological achievements. Researchers can obtain certain

proportion of economic benefits if their scientific and technological achievements can apply in factory production successfully, which creates economic benefits in the continuous 3-5 years. Third, establish the Outstanding Contribution Awarding Fund. Outstanding research and development personnel can gain a large amount of reward if their work is sufficient and leads significant social effect. Fourth, enhance the intensity of spiritual motivation. Award the work staff honorary titles such as professional and technical experts, technical leaders, to stimulate developers to both keeping foraging ahead and working hard.

4.4 Building photoelectron information industry specialization service supermarket

First, pioneering innovation, integration of optoelectronic information field management consulting, administrative examination and approval, coordination and transactional proxy advantage resources. Boosting demand docking with the resources, to build brand, enhance the open sharing of resources, to provide patent data, the current national standard and industry standard queries. Second, the integration of optoelectronic information enterprises in research projects across the country, establishing the talents database of experts in the field, published online network platform functions such as optoelectronic information industry newsletter. Once again, building a diversified investment and financing service system. Optoelectronic information field, establish property right trading platform, and actively introduce risk investment funds and venture capital management companies, set up the province of photoelectron information industry investment fund, key support with independent patent technology product research and development and industrialization.

5 Conclusion

This paper takes the opto-electronic information industry cluster in East Lake High-tech Zone as the research object, through visiting many representative opto-electronic companies in Optics Valley, we summed up the development characteristics, existing dilemma and possible solution of current opto-electronic information industry cluster. The main conclusions are as follows:

The clustering feature of opto-electronic information industry cluster within the region is distinct; regional innovation resources provided effective intelligence support for the development of the cluster; industrial network system which based on innovation network has been initially formed. But the development of opto-electronic information industry cluster still exist some difficulties, including enterprises in the cluster has not yet formed a complete labor division system of industrial chain, lack of coordination and linkage mechanism; most enterprises are still in imitative innovation, and lack of prospective studies; Backbone talents in R&D team of opto-electronic information industry is less stable; soft environment required for the development of industrial clusters is missing. Therefore, this article put forward countermeasures and suggestions from perspectives of build basic research and development platform, improve the industry chain of opto-electronic technological innovation, stable the backbone of R&D personnel, and establish supermarket platform of professional service.

Market Risk and Its Prevention of Discontinuous Technological Innovation

Liu Yaosheng, Yan Jingdong

School of Management, Wuhan University of Technology, Wuhan, P.P. China, 430070

(E-mail: lyshwhut@163.com, yjdong02@163.com)

Abstract: In the 21st century, enterprises are marching toward the fourth generation of technological innovation, represented by the DTI (Discontinuous Technological Innovation). More and more companies have realized that DTI is an important strategic choice to conduct enterprise technological innovation, build technical shields, win new industrial markets and achieve market share breakthroughs. This paper analyzes the features, symptoms and origins of DTI market risk, suggesting to prevent DTI market risk by engaging leading users, combining production, teaching and research, predicting scientifically, testing market demands and establishing strategic alliance based on industrial chains.

Key words: DTI, Market risk, Risk prevention

1 Introduction

Technological innovation, divided into CTI (Continuous Technological Innovation) and DTI (Discontinuous Technological Innovation), is the key point for a country's economic growth and a company's technological advance. Based on the evolving trend of international technological innovation, our world is embracing the fourth generation of technological innovation featuring DTI. DTI, through reorganization of existing knowledge, changes in production techniques and procedures, changes in potential consumer demand patterns, has become important means for today's high-tech enterprises' international competitiveness in developed countries; Thanks to DTI, many companies have achieved a leap forward in technology, got rid of the technical control of others in market competition and created innovation opportunities to produce both new products and new production processes. By opening new market opportunities to companies, DTI is crowned as the driving engines of companies. Although CTI has its own strengths, it is easy to be beaten by DTI (Jill Keyes, 2000). As mentioned by Peter Drucker, we are now in a DTI era, CTI can only be used by companies to maintain their market superiority after the success of DTI.

According to the data, although DTI has 20% success ratio to take back the technological innovation investment and obtain the corresponding returning profit, DTI is also a high risk activity characterized by its systematic and complicated process. As is shown in the research findings by E. Mansfield in 1981, only 60% of research and development by technological companies succeed, among them, only 30% products end up selling to the market. What's more, only 12% of these products win consumer assent. Therefore, if a company wants to gain profits from its technological innovation project, it should take effective means to eliminate or reduce market risk as a priority. In a word, studying DTI market risk management is of vital significance to advance China's independent innovation ability and realize technological advance.

2 Current Situation of DTI Research Both at Home and Abroad

Alfred P. Sloan Foundation from US Rensselaer Polytechnic Institute (RPI) and IRI have a cooperation team working on discontinuous innovation research. After studying a number of cases, they found that success lies in the discontinuous innovation process. Therefore, they concluded that both DTI and CTI would face uncertainties from market and technologies, but uncertainties from resources and organization only belong to the innovation of new business. Growth opportunities matrix proposed by H. Ansoff validates that uncertainties from the market and technologies are vital for DTI. Leifer also conducted a conclusion on the features of DTI life circles. To analyze uncertainties in DTI, Rosenberg proposed six interdependent uncertainties, namely, uncertainties in the competitive market, uncertainties in the innovation technologies, uncertainties in the systematic reorganization, uncertainties in realizing short term profits, uncertainties in satisfying consumer demands and uncertainties in existing competitive technologies. According to Soude and Moenaert, four uncertain factors, namely, competition opponents, consumers, production technologies and costs, will cause huge uncertainties in DTI projects. From the risk perspective, Lynn found that DTI suffers a lot of uncertainties from technologies, market and time arrangement. As mentioned by Hite and Hesterly, uncertainties from task

environment prevent companies from gaining access to the required resources. Bstieler summarized the major effect of environment uncertainty and the regulatory role based on his empirical research. Hareberg discovered the characteristics of non-continuous technological innovation are to put the product from the old market cycle to a new market cycle. According to Richard, Gina and Mark, DTI distinguished its life cycle from CTI as its uncertainties and discontinuation. Lambe and Spekman held that DTI is related to the external links of companies. Foster and Sarah Kapland found that companies which control market channels while proceeding DTI simultaneously can control the invincible position in the market. As we all know, consumer demands are discontinuous in the market. Christian believes discontinuity innovative products should focus on the future needs of consumers through constantly refined methods and it is for more effective to take consumer environment as the foundation than take the consumer characteristics as the foundation. Song and Montoya-Weiss believe that difference in product innovation has an impact on the development process and performance of new products. Marisa Maio and Mike proposed a multiple prediction technique on the effectiveness of combination theory and the philosophy of multiple views.

Compared with overseas studies, research on DTI by domestic scholars is only still in its infancy with relatively fewer corresponding results. According to Liu Yulin, as DTI is established on the basis of new knowledge or knowledge fusion, DTI is much more difficult than CTI. Xu Hejun and Gao Jian think that DTI provides new product values to consumers in the new type of market. After analyzing the relationship between the four modes of technological environment scanning and DTI, Jiang Lihui and Zhang Pengzhu believe that the enterprise's cohesive force when facing market risk decides its DTI decision-making power and control to the innovative risk. Li Anmin designed a new mode of market management after analyzing features of product research and development process, and vertical collaboration research and development form in combination with the features of potential consumers engagement for DTI. This new mode, from the perspective of enterprise knowledge theory, explains the technological and market uncertainties of DTI, knowledge interaction and fusion, knowledge accumulation and creation in the DTI process. Si Chunlin discusses CTI and DTI from both technology and market, holding that discontinuous innovation will adjust and upgrade the existing market structure after its success. Based on the analysis of DTI connotation and features, Ren Jing and Zhu Fangming conduct a special research on DTI in traditional advantage companies, pointing out their setbacks and countermeasures.

From the above analysis, scholars both at home and abroad have developed lots of research on DTI concepts, technological features, market research methods, and so on, which serve as a good basis for future DTI research, but we can also find that studies on DTI market risk prevention are far from sufficient. This thesis studies features and origins of DTI market risks and gives corresponding preventive measures.

3 Features and Origins of DTI Market Risk

3.1 DTI market risk

The DTI market risk refers to the possibilities or chances of non-continuous innovative product not adapting to the consumer market demand and not accepted by the mass market. Such risks originate from enterprises' incomplete understanding of the potential needs of users, unawareness of a potential market and uncertainties of how future market can be transformed into technology and product knowledge. Due to wide time span of the whole DTI process, any link has a high degree of uncertainty, from research and development, selection, project planning, specified marketing strategy, market analysis, sample trial manufacturing, small-scale trial to widespread promotion. The DTI market risks, mainly including the extension risk and the market environment risk, are composed of risks arisen from the preparation stage to the marketing stage.

Continuous risks accumulated in the entire project implementation erupt at the marketing stage most probably. Several situations may lead to continuous risks. Firstly, if a company fails to develop a targeted market research and investigation at the initial stage of a new project, continuous risks may arise. Secondly, if a company fails to develop a tailored research and development for consumers at the new DTI product research and development stage, technical risk will spread to market link which will directly be transformed into market risk. Thirdly, at the new product formation stage, if the product fails to be advanced or useful than the original ones in its quality or concepts, consumers would not be satisfied. Or if there exists some craftsmanship problems, production cost may be too high. All the situations may lead to the eruption of market risks, finally leading to the failure of whole DTI project.

Fast changing market environment will also bring market risk to DTI. First, changes in the macro-environment, such as the legal and regulatory environment, changes in the national policy environment and impact of changes in the production environment on innovation projects; Second, market uncertainty due to changes in the demand and supply for new product acceptance; Third, market entry timing uncertainty which may lead to a blocked marketing channel, causing overstock or dead stock. Fourth, consumers' needs or preferences for products change, thus leading to poor sales; Fifth, fake products or duplicated products of competitors flourishing, which will result in decreased market share of generic products and in product backlog and slow sales of marketing channels Sixth, the industrial chain changes, which leads to fluctuation in the supply and price of raw materials, which will have an impact on DTI, making technical innovation of product faced with sales crisis.

3.2 Features of DTI market risk

DTI is opening up new potential markets for new technologies in orbit, it also faces a high degree of technological uncertainty and market uncertainty, so market risk has its unique characteristics. Firstly, irreversibility. DTI testing starts from the market and ends up with the market, therefore the DTI project needs to formulate effective market risk management to contain each kind of risk from technological innovation, project initiation stage, research and development stage to production stage. Only through continuous improvement and enhanced vigilance can the occurrence of such risks be effectively prevented or corrected. Secondly, source ambiguity. DTI project faces market which cannot be precisely quantified, therefore it is ambiguous. Thirdly, high risk. Since DTI is discontinuous technological innovation rather than original technical improvement, it is faced with bigger technical and market uncertainties.

3.3 DTI sources of market risk

DTI market risk derives from various aspects, among which five main sources may lead to market risk: discontinuous technologies, consumers, competitors, companies and a macro external environment. Firstly, discontinuous technologies causing market risk is shown in the following ways, including discontinuous technologies failure to meet market demand, discontinuous technologies bringing uncertain market opportunities, and discontinuous technologies being uncertain in diffusion extent and tracks. Secondly, market risk brought by consumers. As DTI products end up in satisfying the consumer demands, products which are popular among consumers are successful ones. Since consumer is a vital factor to influence DTI market risk, it is indispensable to develop some research and investigation on consumers. Thirdly, market risk brought by competitors. After DTI products are promoted to the market, they are likely to be imitated or pirated by CTI products, as a consequence, profits are reduced for those new products on market. Companies suffer from gains reduction, with market shares and market returns of the company being impaired, which is manifested in changes in the number of companies, existing competitor strength, potential competitor and substitute condition. Fourthly, market risk caused by companies themselves. As companies are executors of DTI, successful companies should have good marketing strategies, smooth marketing networks, scientific market investigation and analysis, accurate product market positioning, and ample funds, otherwise, companies would find it hard to promote their DTI projects. Strengths and management levels of companies are also vital to the success of DTI products, which can be shown in their effectiveness of marketing strategies, scientific nature of market investigation, accuracy of market positioning, closeness between companies and their supply chain, and funding supply. Fifthly, market risk brought by the macro- environment mainly shown by political environment, economic environment, social environment and technological environment.

4 DTI Market Risk Prevention

4.1 Engaging leading users

Since leading users reflect potential needs of mass consumers to companies in a quick and clear manner, it is necessary for companies which are initiating innovation projects to know the potential demands and thinking pattern of those leading users. During the development stage, companies should strengthen the engagement of leading users and know more clearly about their needs. Only in this way can companies produce popular products, reduce future market risk and increase their profits. As is shown in figure 1, firstly, after predicting the potential market trend, a DTI group is formed, which develops a further market investigation, collect information, expound future trend and potential needs of consumers. Then, an innovation project with its personnel, time and funds will be decided after companies analyze innovation opportunities and business target. At last, an innovation group is set up. Secondly, DTI group positions their leading users, and selects and invites proper ones to engage into this

innovation process to offer help on consumer needs and other information. In this way can innovation group develop products which will be popular in the market based on the information provided by those leading users. More specifically, needs and ideas of products provided by leading users will be studied and developed by the group. After the product is successfully developed, leading users will try them and give their feedback. Then, companies will upgrade their products based on these feedbacks to their satisfaction. Thirdly, after products get their qualification, companies can organize production, marketing and market development.

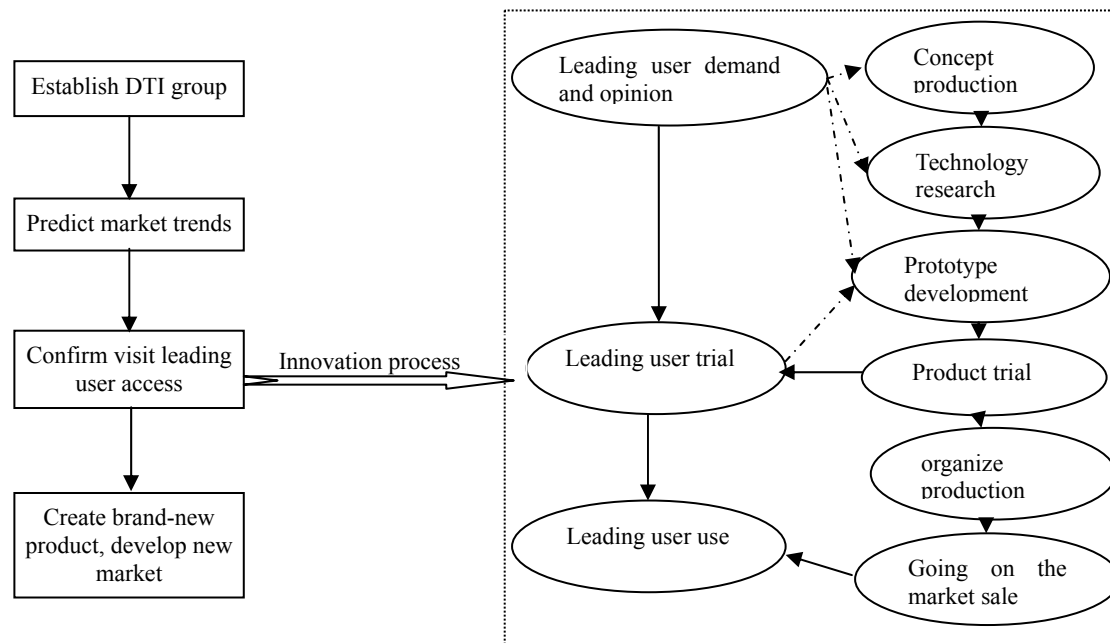

Figure 1 Process of Engaging Leading Users

4.2 Combining production, teaching and research

¹As the consequence of high degree of market risk, and slow progress of discontinuous technologies, DTI products usually have a long period, even the whole period of cooperation with universities or scientific and research institutes. Universities or scientific and research institutes will analyze their respective profits and confronted market risks they starting a segmented cooperation. At the stage of technology preparation, a combination of production, teaching and research will be developed mainly by universities or scientific and research institutes, as they can develop their specific technologies advantages and development abilities, which means they focus more on the technological level. In this stage, companies mainly assemble information collected from feedbacks from leading users and share them with universities or scientific and research institutes. At the stage of technology development, technologies which meet the demands of mass consumer market will be transferred into products, therefore, technical personnel and research resources will be exchanged. Finally is the stage of technical production with enterprise as main position. With the development of new products, enterprises need to have sufficient funds, sufficient workers and strong market channels to promote products, thus gaining profits.

4.3 Scientific prediction and test of market demand

Scientific market demand forecast and precise market test involve the following aspects. Firstly, predicting market demands requires covering all the necessary estimation or data, collecting ideas from key shareholders and keeping their original ideas. Secondly, market test refers to develop trial sale through a selected channel for a product in a specific small area. According to the rule of Chinese market, the trial sale of product will be arranged in coastal areas or the provincial capital of central China as consumers in these areas can represent potential needs of most consumers. If the products sell well in those cities, they can be launched into the national market. Market test enables companies to

¹ Ge Ruyi. Zhang Pengzhu. Continual technological innovation industrial-university collaboration evolution model study [M]. China science and technology forum, 2008

know if their technology has satisfied consumer needs, and find wrong supposition and unexpected results. In this way, companies can adjust incorrect behavior, define user preferences and target market positioning. Moreover, market test can predict how large consumer group is and whether they can distribute products on a large scale or not. If new products fail to pass a market test, companies should stop production and curb market risks as early as possible.

4.4 Establishing strategic alliance based on industrial chains

To reach common profit goal, allied companies will assemble their respective strengths and good resources, thus developing new innovative products, exploring a new consumer market and winning more profits for companies. In implementing DTI process, it is of vital importance to establish strategic alliance based on industrial chains. Technology patent owners will provide strategic theory research for products, material suppliers producing products with mature and stable production lines, consumers giving feedback on products through improved sales and service channel, and technology patents developers improving their quality to meet market demands again. Thanks to the complementation of advantageous resources of all allies, values of resources are maximized. The whole ally has become the symbol of the industry. Therefore, seeking cooperative industrial chain partners can Enhances the competitive advantage of entire alliance, complete the development of discontinuous innovative product jointly and reduce market risk.

Analysis of Synergy Development System of New Energy Automobile Industry

Zhang Yan

School of Foreign Languages, Wuhan University of Technology, Wuhan ,P.R.China 430070
(E-mail: swallowgarden@163.com)

Abstract: This paper has made a research of the development of new energy automobile industry (NEAI) by means of synergetic theory. NEAI is regarded as a system, a performance function is proposed for analysis of the new energy automotive industry. At the same time, collaborative development models are used to analyze the synergetic relationships between new energy automobile industry and other subsystems. After the new energy automobile industry development system meet disturbance, how to dynamically adapt and adjust so as to keep the coordination development will require intensive study by means of the synergy mechanism.

Key words: New energy automobile industry; Synergetic theory; Synergetic development

1 Introduction

Wang et al. ^[1] analyzed the industrialization of new energy vehicles in the policy problems facing the technology research and the product standard infrastructure problems, and carried on the thorough system's research. Du et al. ^[2] developed an enterprise collaborative management system based on synergetic theory. This system is used to make an integration of enterprises, upstream and downstream resources so as to achieve comprehensive collaborative management of all kinds of resources in addition to the manufacturing, inside or outside the business. Liu et al. ^[3] analyzed on the status of China's new energy automotive industry collaborative innovation, and constructed a theoretical model of the new energy automotive industry collaborative innovation by means of the modular theory. Pan ^[4] illustrated the need for the development of new energy vehicles in China, and demonstrated a detailed analysis of the current domestic and foreign new energy vehicle development status quo, and clearly pointed out a few questions of the development of new energy vehicles, focuses on the development of new energy car policy recommendations.

Above mentioned methods are qualitative analytical methods. Therefore, in this paper, the concept of "functional structure" in ^[5] is introduced to quantify the collaborative relationship between new energy automotive industry and other corresponding industries.

2 Function Analysis of New-Energy Automobile Industry Development System

2.1 Basic evolution equation of the system based on synergetic

According to synergetic theory, basic evolution equation of the system is q and its different-order derivative equations. The general form of the equation is $q(X,t) = N(q(X,t), \nabla, \alpha, X, t, F)$. This equation has the following characteristics:

(1) It can be represented by the state variables. q , which is a function of both coordinates and time, is the representation of the system's state variables in the equation. Since synergetics is an enormous one, it consists of a great number of subsystems. The number of state variables used to describe behavior of the system can be huge. Given this, for simplicity, state variables are always used to represent this.

$$\mathbf{q}(X,t) = (q_1, q_2, \dots, q_n)$$

(2) All-order derivatives of state variables are related to state variables itself and as basic evolution equation of the system are nonlinear. They reflect the interaction of the internal different factors of system.

(3) Factors such as diffusion or wave transmission to be deal with is in a heterogeneous medium. Space derivative should be included in the basic equations, Hamiltonian operator and Laplace operator. Basic evolution equation using the form of partial differential equation:
 $\Delta = \partial^2 / \partial x^2 + \partial^2 / \partial y^2 + \partial^2 / \partial z^2$

The evolution behavior of the system can be studied by determining the dependence of state variables to space-time. From a mathematical point of view, the basic equation can be solved in principle, as long as the appropriate initial conditions or boundary are given.

2.2 Functional function of new-energy automobile industry system

The function of new-energy automobile industry system is reflected in four aspects: the status of new-energy automotive industry itself, the status of economic subsystem, the status of social subsystem, the status of ecological subsystem. According to the basic evolution equation of the system, the function of new-energy automobile industry system can be expressed as $TF = f(S_1, S_2, S_3, S_4)$, where S_1 is the status of new-energy automotive industry, S_2 is the status of ecological subsystem, S_3 is the status of social subsystem, S_4 is the status of ecological subsystem.

To improve the value of TF , intense research of $f()$ function must be done. However, since the specific form of $f()$ function is hard to proof in the tier of theory. But if we consider it from the specific meaning of $f()$ function, since the function of new-energy automobile industry system is continuously changing, it is always continuously differentiable although the speed of TF varies. We can get the expansion of TF as $TF = f(S_1, S_2, S_3, S_4)$, and then let $M^i, i = 3, 4, 5 \dots$ $\mathbf{I} = [1, 1, \dots, 1]$, a variation method is adopted for TF function $\delta TF = TF - f(S_1, S_2, S_3, S_4)_0 = \mathbf{I}(\mathbf{M}^1 + \mathbf{M}^2 + \dots)\mathbf{I}' = \Delta_1 + \Delta_2$

In the above formula, $\Delta_1 = \mathbf{I} \cdot \mathbf{M}^1 \cdot \mathbf{I}'$ means contribution of improvement of each of the four subsystems which is a direct role in contribution to δTF , $\Delta_2 = \mathbf{I} \cdot \mathbf{M}^2 \cdot \mathbf{I}'$ means contribution of subsystems after they coupling between every two subsystems which is a second role in contribution to δTF and $\mathbf{I} \mathbf{M}^i \mathbf{I}'$ is i th role in contribution to δTF . $\sum \mathbf{I} \mathbf{M}^i \mathbf{I}'$ means the sum of contributions of interaction of the i th items. In this way, the following situations may occur: Case1 $\Delta_1 > 0$, $\Delta_2 < 0$, $|\Delta_1| > |\Delta_2|$, $\delta TF > 0$; Case2 $\Delta_1 > 0$, $\Delta_2 < 0$, $|\Delta_1| < |\Delta_2|$, $\delta TF < 0$; Case3 $\Delta_1 > 0$, $\Delta_2 > 0$, $\delta TF > 0$; Case4 $\Delta_1 < 0$, $\Delta_2 < 0$, $|\Delta_1| > |\Delta_2|$, $\delta TF < 0$; Case5 $\Delta_1 < 0$, $\Delta_2 > 0$, $|\Delta_1| < |\Delta_2|$, $\delta TF > 0$; Case6 $\Delta_1 < 0$, $\Delta_2 < 0$, $\delta TF < 0$. The first two situations indicate that the status of subsystems improved while the overall function is destroyed. But case1 is a little better because it still does some contributions to the overall system as $|\Delta_1| - |\Delta_2| > 0$ while case2 is made a negative contribution as $|\Delta_1| - |\Delta_2| < 0$. Case3 is the best situation, the function of both the overall system and subsystems are improved. In Case4 and Case5, function of subsystems are weakened while improve the function of the overall system. Besides, in Case 5, improvement of the overall system's function is bigger than in Case4. Case6 is the worst one which the function of both subsystems and the overall system are destroyed.

On the basis of the above analysis, we can conclude that the improvement or attenuation of subsystems can lead to the decline of function of the overall system, but it can rise. The essence of improvement of the system's function is weather the changes of subsystems is collaborative or not, from which we can get the biggest value of Δ_1 and Δ_2 .

3 Synergy Analysis of New Energy Vehicles Industry Development System

According to the above analysis, the realization degrees of function of new-energy automobile system depend on the coordinative degree of its subsystems' changes. In other words, the essence of the development of new energy automotive industry is the process of coordination and co-evolution of new-energy automotive industry itself, economic subsystem, social subsystem and ecological subsystem. For example, linkage of the subsystem: $H = h(h_1(s_1), h_2(s_2), h_3(s_3), h_4(s_4))$, where, H is coordination of new-energy automotive development system, h is collaborative coefficient. Performance of collaborative of subsystem itself:

The new-energy automobile industry is of high-input industry needs substantial capital investment which is depend on the market risk of the high-tech industry and the character of high-tech's knowledge intensive and talent-intensive. As new-energy automobile industry is high-tech industry, fast in technology update speed, large in equipment investment, short in product life cycle, enterprise needs a large number of investments to achieve economic scale quickly and meet the needs of the development. Some of new-energy automobile industry is strict controlled by the government. Product development conditions and quality of products have a great affection on public security and new-energy automotive

safety. So the government has strict regulations in this industry. For example, we have strict statutes, regulations, quality specifications, and marketing approval in the development, production and sales. Industry regulations and industrial policies are important factors to influence the development of new energy automotive industry.

Effective organization and integration of industry resources and elements can lead to a good market performance using appropriate market behavior in a rational market structure. We can achieve the function of subsystems through adjusting the structure of the system. The industrial structure of new-energy automobile is made up of the ownership of productions of the new-energy automobile industry, industrial demand, factor supplies, trade and investment. Adjustment and optimization of the industrial structure can improve the function of subsystems and promote development of industry. The behavior subjects includes the core behavior subjects-enterprise within the industry and intermediate behavior subjects-government organizations, academic institutions and intermediary organizations related to corporate activities. The innovation ability of enterprise is built in industrial administrative level. Industrial development is the highest level and the end-result of enterprises development.

The coordination between the subsystem of new energy vehicles industry and economic subsystem bring satisfactory economic benefits, the new energy auto industry has a good economic benefit, which is the most direct power of the industrial development and the most basic requirements. Only when enterprises think that the industry brings them to the expected economic benefits, they will invest in the industry. The synergy between social subsystem and new energy vehicles industry is refers to the industry to meet the requirements of the local people, drive the development of relevant industries, solve the problem of employment, improve the level of income and life quality, improve the culture and health conditions, promote the balanced development of society, plays a positive role for social progress and development. Generally, direct economic benefits easy to appear, but from the perspective of the whole society, is more emphasis on social benefits. Figure 1 has shown us that the car sales enjoys an continuous increasing due to the growth of GDP which contribute a lot to the nation's need of cars.

Figure 1 The Trend of Car Sales and China's GDP During 2006-2012

The coordination between new energy vehicles industry and ecology is refers to the industry sectors by means of the rational allocation of resources to achieve profits, and the continuous changes of the regional and national ecological environment policies to adjust their behavior, improve the utilization rate of resources, environmental protection measures, reduce waste emissions and pollution of the environment, improve the ecological environment of external influence. Which will significantly affects the costs and benefits. In the long run, industrial development of the external economy will gradually internalize so that synergy between new energy vehicles industry and ecology will reduce the external economy, which is conducive to the sustainable development of the industry. Overall coordination development of new energy automobile industry is that the developments of the new energy vehicles industry itself, and the economic, social and ecological subsystem are synergetic, such as reasonable composition, technological innovation, organizational innovation and market innovation synergy development, industrial core competitiveness are simultaneously improved, which conforms to the social needs, solves the employment problem, improves the living standards, maintains public health security, save resources, reduces pollution, and maintains the ecological balance. Synergies between each other can realize the sustainable development of new energy automotive industry. For example, Fig.2 shows car sales of EV and HEV in China during Nov.2011 to August 2012, from which we can see the prospects of HEV is better than EV. Because the general used of EV needs infrastructure construction such as charging stations which is mainly collaborative with EV products.

Figure 2 Car sales of EV and HEV in China During Nov.2011 to August 2012

4 Conclusions

The synergy theory was introduced into the research of new energy automobile industry development in this paper, function analysis and coordination analysis were also carried about new energy automobile industry development system, and put forward new energy automobile industry coordinated development pattern. But between the subsystems of new energy automobile industry development system, how to make the government guide ability, science and technology support ability, the market supply ability and the enterprise competition ability cooperate much more. Due to the openness, flow resistance, complexity of the system, the system always meet all kinds of interference, old collaborative state must be broken, system evaluate to a new state. After the new energy automobile industry development system meet disturbance, how to dynamically adapt and adjust so as to keep the coordination development will require intensive study by means of the synergy mechanism.

Research on the Innovative Design of Tourism Products in Jingzhou of China

Zhao Junjing

School of Art and Design, Wuhan University of Technology, Wuhan, P.R.China,430070
(E-mail: Id_zhao@126.com)

Abstract: This paper mainly discusses the innovative design of tourism products in Jingzhou China. With probing into the current condition of the tourism products in Jingzhou, the paper adopts the SWOT approach to demonstrate the strengths, weaknesses, opportunities and threats of the innovative design of tourism products. Based on the exploration of the traditional artistic and cultural features in Jingzhou, the paper proposes the positioning strategies of innovative design on tourism products in Jingzhou, and determines its design concepts, major consumer groups and design style. With the combination of the macro and micro analysis, the paper provides a sensible insight into the innovative design of tourism products in Jingzhou.

Key words: Tourism product; Product innovation; Design orientation.

1 Introduction

Product innovation is the main focus and major difficulty in the development of modern enterprises and regions. Due to lack of rigorous and unified definition about product innovation, Organization for Economic Cooperation and Development (OECD) states that product innovation is a kind of technical adoption of products with the aim to provide advanced or better service for product consumers. Professor Fu Jiayi from Tsinghua University credits that the purpose of product innovation is to get new or improved products. Professor Hu Shuhua in Wuhan University of technology announces that product innovation has a very wide range of content which includes functional innovation, formal innovation and service innovation, corresponding to the stage of product planning, the stage of design and manufacturing, and the stage of market entry. From the above-mentioned opinions, product innovation is the focus of industrial enterprises and the target of regional product planning and design. Therefore, the thesis mainly deals with the innovation design of tourism products in Jingzhou.

As a famous historical and cultural city, as well as the birthplace of Chu culture, Jingzhou has abundant tourism resources. However, present tourism development in Jingzhou is still at an early stage. Among the great reasons, the most important one must be insufficient design and research on local tourism products. If full understanding about the unique characteristics of Jingzhou's tourism resources were done and deepening exploration of Jingzhou's tourism products were made, distinct and attractive design could be achieved to promote and facilitate the tourism and economic development in Jingzhou, and could assist Jingzhou in setting up and spreading city image.

2 Present Status of Tourism Products in Jingzhou

2.1 Status analysis

At present, Jingzhou's tourism products can be basically divided into the following categories:

Tourist handicrafts: Hu Zuo Niao Jia Drum (the drum with tiger-shape seat and bird-shape stand); Hu Zuo bird (A flying bird on the tiger-shape seat); Lying Deer; Jing Satin, etc. Being significant symbols of Chu culture and revealing great commemorative functions, the above handicrafts possess regional characteristics and distinctive Chu cultural features.

Tourist goods: Honghu feather fan.

Tourist food: Jiangling eight-treasure rice pudding (stewed glutinous rice with bean paste, lotus seeds, preserved fruit, etc.) Jiu Huang cake (traditional food in Jingzhou which gets the name due to beautiful color of chrysanthemum around the Double Ninth Festival); Sha Daoguan Chicken; Jingzhou fish cake, etc. This kind of tourist food, as the above mentioned, usually has a strong flavour, a long history, exquisite allusions, beautiful legends and certain reputations. They commonly possess elegant craft and beautiful packaging, novel style and distinctive commemorative and practical meanings.

However, Jingzhou's tourist commodities generally lack variety and high quality. Therefore, foreign and domestic tourists always find it difficult to purchase satisfying tourist goods in Jingzhou.

2.2 Existing problems in the exploration of tourism products in jingzhou

(1) The tourism commodities which can reflect regional characteristics, such as handicraft articles

or local special products are nearly under insufficient development or undeveloped.

(2) As far as the developed products concerned, a class of phenomena, such as going after the far-away at the expense of the near-at-hand, or a turtledove taking over the nest of a magpie, is of common occurrence, due to one-sided pursuit of profit.

(3) There is no systematic and programmed administration on the developed products. Moreover, the supply and marketing are sometimes disconnected.

(4) The quality and packaging of tourism commodities need to be further enhanced.

(5) Originality and elegant taste are required.

(6) Propaganda and notability are to be promoted.

3 SWOT Analysis Method in the Innovative Design of Tourist Commodities in Jingzhou

3.1 Analysis of strengths

Jingzhou's strengths lie in its profound cultural deposits. Jingzhou is one of the well-preserved ancient cities in China. It is located in the intersection of three kinds of culture which include Chu culture, the culture of Three Kingdoms and water culture. As multicultural convergent points attract more and more domestic and international attention and exploration, their significant value grows to be recognized by more and more people. In particular, the fusion of the novel *Romance of the Three Kingdoms* and the historical facts of the wars among Wei, Shu and Wu becomes the great wealth of Jingzhou. In addition, Jingzhou is rich in historical and cultural tourism resources. The strength activated by the integration of history and culture seems a powerful magnet.

The surrounding cities, such as Wuhan, Yichang, etc. are inferior to Jingzhou, as far as Jingzhou's abundant cultural connotation, deep Chu culture basis, and moving stories of the Three Kingdoms concerned.

3.2 Analysis of weaknesses

Firstly, the foundation for product development is weak. Concerning product type, Jingzhou has developed various tourism products for sightseeing, leisure, festivals or significant events. However, a transitional and promotional tourism product chain has yet to be formed. In Jingzhou, only static display is provided to promote the vast majority of tourism products. Tourists can only appreciate the illustration of scenic spots and listen to the explanation given by tour guides, but seldom participate in interactive activities, which contributes to low interest and low re-travel rate of tourists.

Secondly, tourism marketing does not reach the designated requirements. As a special industry, tourism needs effective promotion and marketing, because of the immovability of the tourist attractions.

3.3 Analysis of opportunities

Firstly, Hubei province sets the Three Kingdoms culture tourism as the key to cultivate and develop. In order to launch the Three Kingdoms culture tourism hotlines, great efforts are exerted in integrating resources and attracting extensive investment. Besides, the Three Kingdoms culture is hot recently throughout the country and around the world. As a key part of the Three Kingdoms culture, Jingzhou need to usher in this rare exploring opportunity and broad developing space.

Secondly, vigorous support is given by authorities to develop the tourist industry in Jingzhou. Without effective support of the government, it is impossible for a city to establish well-developed tourist economy. Moreover, it has already been confirmed that Jingzhou municipal party committee and municipal government has incorporated tourism development into the national economic and social development plan, and will support its development as the important pillar industry.

3.4 Analysis of threats

Firstly, regional tourism is now faced with great pressure of competition. Jingzhou is surrounded by Wuhan East Lake, the Three Gorges, Zhangjiajie, and Wudang Mountain. These scenic spots, having had high popularity and great reputation at home and abroad, all belong to state-level scenic spots or world cultural and natural heritages.

Secondly, as the tourist market becomes fully open, and more and more tourists from all over the world will gather in Jingzhou, tourism hardware and software facilities are confronted with great challenges. Six basic requirements of travel consumers from different countries and different regions are needed to satisfied, including food, housing, transportation, travel, shopping and entertainment. In actual reception activities, the obstacle of the language is another difficulty to overcome. A large number of high-caliber reception personnel are needed, such as tour guides, hotel service personnel, and even common residents of the city.

4 Design Strategy of Jingzhou's Tourism Product Innovation

In view of the present situation of tourism products in Jingzhou and the existing problems, the innovation design of Jingzhou's tourism products should lay great emphasis on the refinement of the traditional art and culture. At the same time, it should make sure the design orientation of the tourism products which involves design concept orientation, consumer groups orientation, and design style orientation.

4.1 Analysis of the traditional art and culture

First, Great emphasis is put on romantic and abstract forms in Jingzhou culture. Though there are some realistic and recurrent forms, Jingchu artistic forms are mainly romantic and abstract. They reject the faithful copy of objects and don't follow strict programs or rules. They reflect and display the diversity of objects by using metamorphic and exaggerated forms. For instance, Hu Zuo Niao Jia Drum (the drum with tiger-shape seat and bird-shape stand) has light-footed and graceful form

(Figure 1). It embodies a sense of music by adopting the symmetry structure of mortises and tenons. The body of the phoenix exhibits a smooth S curve and is full of a sense of movement. On the contrary, the tiger-shape seat's fruity modeling gives a stable and steady expression to the viewers.

Second, it has the beauty of decoration. Lacquer, one of the Jingchu arts, is the best artistic form to exhibit the beauty of ornament, because of its distinctive decorative patterns. In addition to the skillful use of C shape line to form a variety of continuous patterns, Jingchu lacquer often adapts the general pattern composition principles to designing different shapes flexibly. Besides, the beauty of Jingchu lacquer lies in its dynamic pattern expressed by decorative lines. For example, the pattern of painted lacquer coffin is made up of flexible curves of different length.

Third, it has spectacular color beauty. Jingchu lacquer mainly adopts two colors, red and black, occasionally supplemented by yellow, green, blue, white and so on. A kind of spectacular beauty appears by the bright contrast of the color of red and the color of black. Jingchu lacquer's colors not only emphasize the contrast of the color applied in large blocks, but also pay attention to the subtle color change and transition.

4.2 Design concept orientation

Tourism products work as the medium to transfer abundant information of the tour destinations. Well-made tourism products give visitors a pleasing feeling, and provide visitors' relatives and friends with a preliminary understanding and a good impression of the sightseeing places, because tourism products display regional concentrated culture essence. As for the design concept, Jingzhou tourism products should have four design concept orientations as follows.

First, local characteristics

Tourism products lack personality and follow the same pattern. Enterprises which produce and market tourism products do not have strong brand awareness, which provides opportunities for peddlers of lucrative short cuts to counterfeit. They don't implement effective management for their brand and scale operation of new products, so tourists always feel confused when purchasing. "Special" consciousness should be the directive principle for design. Tourism products should be "distinctive" and "unique". They should express ethnic characteristic and regional characteristics, and they should play a part in spreading knowledge, attracting interests, and conveying memorial concepts.

Second, high quality awareness

Although tourism products are small products, it never means they can be crudely made. Enterprises should have quality awareness when they design and produce tourism products. A crudely-made tourism product, even though it has great originality and innovation, will definitely damage the image of the city and will certainly affect sales.

Third, cultural connotation

Figure 1 Hu Zuo Niao Jia Drum

Culture is the connotation and soul of tourism, while tourism is the carrier and manifestation pattern of culture. For tourists, to travel is to experience the local customs. "Local" goods are more attractive to tourists because of different life style and concept contained in them. Therefore, it is essential to blend local culture with the design of tourism products.

Fourth, convenience

Tourism product design should also take the distinguishing features of tourism into consideration. Tourists often have to travel long distance and have to change vehicles frequently, so tourism products must be small, light, fast and flexible, and make sure they can be easily carried and well preserved.

4.3 Major consumer groups orientation

According to the analysis of the tourist market issued by Jingzhou City Tourism Bureau, Jingzhou Three Kingdoms culture theme park has great potentiality and good market prospects. Details are listed as follows:

1) On average, the total number of tourism reception in a year is more than 4,000,000.

2) After the theme park is built up, the tourist market can be subdivided into four parts:

One is the central area of Jingzhou City. If the total number of the residents in central area is 750,000 and only 5% of them come to visit the theme park each year, the tourists will be 40,000.

The second part is the potential tourists in the surrounding counties or cities which are under the authority of Jingzhou. If the total population of these counties and cities is 5,700,000 and 3% of them will visit the theme park, the tourists will be 170,000.

The third part is the transit visitors who will visit Three Gorges and nearby attractions. The tourists in this part will be 450,000.

The fourth part is the overseas market which mainly includes the tourists from Japan, Korea, Southeast Asia, Europe or the United States. The largest number of tourists amounts to 130,000.

Through data analysis, it is concluded that major source of tourists in Jingzhou should be from local and surrounding provinces and cities. Domestic tourists are in the majority, and the rest are foreign visitors or transit visitors.

In consideration of the long-term development of Jingzhou tourism, overseas visitors who have a certain economic ability and are interested in the Three Kingdoms culture should be the target consumer group of tourism products design.

4.4 Design styles orientation

The key of the innovative design of Jingzhou's tourism products is to reflect the Jingchu features. There is great connection between the unique cultural and natural environment in Chu places and the occurrence, development and evolution of Chu culture, which derives from the cultural exchange between the north and the south. Therefore, the style orientation of the innovative design of Jingzhou's tourism products can keep to the following principles.

Firstly, affective, and imaginative type

Secondly, unrestrained and bizarre type

Great attention is put on emotional expression and the development of free personality.

Thirdly, lively, romantic and free type

Fourthly, relaxed, exquisite and dynamic type

Advocate the beauty contained in the natural movement of life and think highly of delicate and deep feelings.

5 Conclusion

This study aims to reflect the cultural characteristics of Jingchu. Detailed analysis has been done to demonstrate the strengths, weaknesses, opportunities and threats in the exploration of tourism products in Jingzhou. Besides, the research probes into the artistic features of Jingchu culture and proposes rational positioning strategies for innovative design of Jingzhou's tourism products, including design concept positioning, target group positioning and design style positioning.

Based on the combination of macro and micro analyzing methods, this thesis provides insight for innovative design of tourism products in Jingzhou, and offers effective instruction to enhance the level of Jingzhou's tourism products, satisfy various demands of tourists from all walks of life, and highlight the distinctive characteristics of Jingzhou's products.

Synergy Innovation Pattern on New Energy Vehicles Industry

Zhang Yan

School of Foreign Languages, Wuhan University of Technology, Wuhan , P.R. China ,430070
(E-mail: swallowgarden@163.com)

Abstract: This paper analyzes China's new energy automotive industry collaborative innovation on the basis of a synergy theory, and then a modular theory is introduced to construct synergy innovation model to analyze the development strategy of new energy automotive industry. China's new energy automotive industry should improve standard system, cultivate leading enterprises, and increase investment on research and development. Moreover, the vehicle and parts enterprises should strengthen the capability of the collaborative innovation, so that the collaborative innovation capability of the whole industry chain can be promoted.

Key words: New energy vehicles; Development strategy; Synergetic development.

1 Introduction

With non-renewable resources dwindling, environmental pollution and other problems have become increasingly prominent, China's automobile industry bear Enormous pressure on energy saving, rationalization structure adjustment of automotive products become urgent to meet the needs of sustainable development of society. The white paper (China's Energy Policy) issued by the state council mentioned that our current dependence on foreign oil has reached 57%, while nitrogen oxides of the motor vehicle emissions have also been accounted for over 40% of total emissions, which cause to occur frequently some areas of regional of air pollution problems, resources and environmental problems to be solved. New energy vehicle development is an important measure to realize energy conservation and emission reduction in recent years, state and local government has issued a series of incentive policies to support the development of this emerging industry.

The demonstration project of 2009 "Ten City 1000 cars" to promote the application of new energy vehicle was started. The range of efforts to support and benefit administration should be subsequently implemented, deepened and expanded. 2010 in some pilot cities, "regarding the development of the private purchase of new energy vehicles subsidy pilot" program is implemented. In June 2012 the State Council issued the "energy saving and new energy automotive industry development plan (2012-2020)" is aimed at vigorously promoting, fostering and developing new energy automotive industry. At the same time, 2012 is a deadline year of " ten city thousand cars " policy, some cities have introduced policies to support and foster new energy vehicles, such as Shanghai, the former 20,000 new energy vehicles are free of charge on the card, Guangzhou issue a limited license for cars, however, provide the new energy Auto with an open green channel. Therefore, the development of new energy automotive industry has again been a huge boost. In this period of time, new energy auto, such as plug-in hybrid electric vehicle (PHEV), Pure electric vehicles, and Fuel cell vehicles, these new energy automobiles are obtained a very good development as Figure 1 and Figure 2.

At present, lots of literatures analyzed Current situation and strategy of Chinese new energy automobile industry, Zhang et al. ^[1] built a collaborative innovation model of new energy automotive industry chain. In this framework, the automobile companies play the role of helmsman industry, automobile industry, as whole, including systems integration design rules and new energy professional standard functional criteria of two parts. Jiu ^[2] expounded that a unified standard system of new energy vehicles is of strategic importance to improve the development of new energy automotive industry, therefore, the standardization and internationalization are promoted as soon as possible. Li ^[3] proposed that a leading enterprises should be prior cultivated, and then the development of a leading enterprise drives synchronous development of other corresponding enterprises. Liu et al. ^[4] analyzed on the status of China's new energy automotive industry collaborative innovation, and constructed a theoretical model of the new energy automotive industry collaborative innovation by means of the modular theory. On basis of the above mentioned analysis of the new energy automobile, in this paper, the concept of "Synergy Theory" in ^[5] is introduced to quantify the collaborative relationship between new energy automotive industry and other corresponding industries.

Figure 1 New energy automobile production situation

2 Modular Construction of New Energy Automotive Industry for Synergy Innovation

China’s new energy automotive industry has formed a “three vertical and three horizontal” development layout. From the perspective of the modular division of labor, specific modular forms includes a multi-function powertrain control system module, motor and control system module, battery and its management system module, the traditional components module sub-module. Among them, the complete vehicle enterprise is commonly regarded as helmsman module, in Fig.3. System Module is the new energy automotive industry chain is the most critical aspect is the new energy vehicles is different from conventional cars core areas. Automobile companies are core aspects of the whole industry chain are responsible for the power train control system and other modules for system integration, which is the ultimate vehicle control integration.

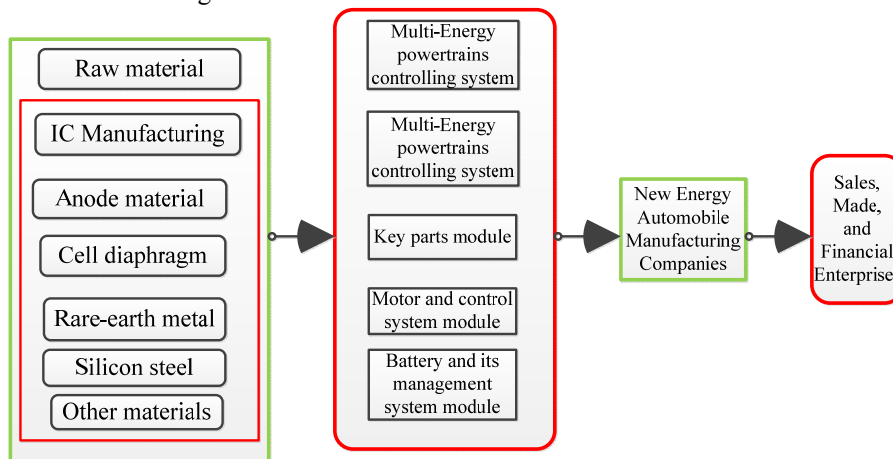

Figure 3 New energy vehicles industry structure under the condition of modular division

Development requirements of China’s new energy automotive industry for synergy innovation are mainly based on the following three aspects:

The first is that key technology bottlenecks require enterprises to strengthen the chain innovation and cooperation. New energy automotive industry each module is a technical chain, which has involved

a wide range of technical research and development, innovation difficult, technically closely linked features. Independent research and development of individual enterprises are often stretched to closely, jointly work from upstream to downstream enterprises. Consequently, development goals and technological breakthroughs can be obtained.

The second is that technical standards are unified so that collaborative and innovative ways can achieve the required standards formation of industry. lots of new energy vehicles companies currently exist at china, but the industry standards of new energy automobile are not unified, modular design deficiencies, each enterprise only seeking its maximal self interest, which lead to drastically contest with industry-standard, finally resulting in duplication of resources configuration. A competition of international standard of new energy vehicles can objectively require the unification of the domestic industry standards as soon as possible.

The third is that synergy innovation ways can facilitate collaborative research and development, cost reduction and efficiency improvement of industrial research. New energy automotive technology complex issues of individual enterprises to carry out technological innovation activities alone, research and development costs remain high. By industry collaborative innovation method, costs and risks of innovation in the industry chain effectively can diversify and enhance the efficiency of the overall innovation industry.

3 Synergy Innovation Analysis on China’s New Energy Automotive Industry

3.1 Industrial innovation synergy design elements

From synergy innovation decision to end of synergy innovation in the whole process, in accordance with principles of the order parameter of synergetics, in this paper, industry synergy innovation dimensions will be divided into innovation goals synergy, interest in equity arrangements synergy and relationship capital synergies. Among them, equity arrangements synergy and capital synergies can provide innovation goals synergy with contractual and non-contractual guarantees; innovation goals synergy show real value of equity arrangements synergy and relationship capital synergies. Since any one industry chain is closely related to the external environment, therefore, changes of the external environment synergy will have an impact on the effect of industry synergy innovation. Therefore, this paper, industry innovation synergy evaluation criteria includes four aspects: innovation goals synergy, equity arrangements synergy, relationship capital synergies and the external environment synergy. The specific form is listed in Table 1.

Table 1 Synergy Innovation Structure Factors of New Energy Automobile Industry

Objection Layer	Criterion Layer	Indicative Guideline
Synergy Innovation	Innovation objection synergy	Innovation Goal Congruence
		Innovation Goal Value
	Equity arrange synergy	Innovation investment and benefits to match
		Innovation income and risk matching
	Relation Capital synergy	Trust relationships among enterprises
		Synergy culture of industry innovation
	External Environment Synergy	market competition environment
		Policy environment of government

3.2 Sample data dealing with method

For the purpose of describing relationship of the mutual influence of different modular factors F_{ij} is introduced to depict the effect of f_j on f_i , however, no synergy degree of factor f_{ij} can be expressed as $f_{ij} = F_{ij}/e$, e is level number. No synergy matrix is used to measure the mutual effects of between systemic elements, k_{ij} denotes results of influence of the them, it can be expressed as $k_{ij} = (k_{iIdeal}^j - k_{iActual}^j) / k_{jIdeal}^i$, here, k_{iIdeal}^j is an ideal match value of the k_j expectation k_i , $k_{iActual}^j$ is an actual match value of the k_j expectation k_i , k_{jIdeal}^i is an ideal match value of k_i expectation k_j , $k_{jj} = (k_{jIdeal}^j - k_{jActual}^j) / k_{jIdeal}^j$, k_{jj}^j is an optimal match value of itself k_j ,

$k_{jActual}^j$ is actual match value of itself k_j . And then, the total no-synergy degree can be expressed as

$$m_{ij} = k_{ij} / \sum_{j=1}^n k_{ij}$$

. By means of the above mentioned expression and some given parameters from the

product enterprise, no synergy degree can be obtained. At given the corresponding parameters of some enterprises, no synergy degree, constraint degree, absolutely no synergy of industrial chain of various subsystems are show in Table 2.

Table 2 Each Subsystem No Synergy, Constraint Degree and Absolutely No Synergy

Evaluation index items	Innovation objection synergy	equity arrange synergy	relation capital synergy	external environment Synergy
No synergy	0.4890	0.4912	0.5260	0.5362
restraint degree	0.4720	.04652	0.5210	0.4910
Absolutely no synergy	0.8960	0.9028	0.9552	1.0102

4 Conclusions

Therefore, in the future course of development, China's new energy automotive industry should focus on accelerating the development of technical standards and upgrades, and strive to become the industry standard national and even international standards, furthermore, enhance innovation synergy targets, reversing no synergy of equity arrangements. Meanwhile, the favorable conditions and relevant industrial policies of state can be fully utilized to strengthen division of labor and collaboration of the various industrial chains so that the efficiency of industrial synergy innovations can be significantly improved.

(1)Improve the standard system; accelerate the process of internationalization of industry standards. Standard system and the promotion of new energy automotive industry is the most important development.

(2) Cultivate leading enterprises to joint development of industry leading enterprises.

(3)To increase R & D investment should strengthen technical cooperation between enterprises modular. New energy vehicle technology research and development with high investment, long cycle characteristics, high yield but also faces enormous technical risks.

(4) Government should be active involved in the industrial technology innovation and building a service platform.

Abstract: Standard inspection process is the standard of all the quality inspection activities. SIP establishes the validation station through the key position in manufacturing process, inspecting according to standardization, preventing defects escape, making the manufacturing process quality visualized, and providing the basis for improving the product quality continuously. Therefore, SIP station is the most basic quality information collection units. This paper describes quality standard for inspection and the standard inspection process in automotive manufacturing.

Key words: Standard inspection; Quality standard; Automotive manufacturing

1 Introduction

Inspection is, most generally, an organized examination or formal evaluation exercise. In engineering activities inspection involves the measurements, tests, and gauges applied to certain characteristics in regard to an object or activity. The results are usually compared to specified requirements and standards for determining whether the item or activity is in line with these targets^[1]. SIP station records the quality testing information in various manufacturing process, feedbacks timely, and ensure the next operation complete successfully. The information which SIP station is the only source of quality information in manufacturing process.

2 Quality Standard for Inspection

An inspection is defined as a process that evaluates, reviews and analyzes the programs and activities of providing information to managers for decision making. Inspections may be used to provide factual and analytical information, monitor compliance, measure performance, assess the efficiency and effectiveness of programs and operations. A key aspect of inspection quality control is adequate supervision. Supervision provides important judgment and an additional level of oversight to the work done by subordinate, often less experienced, staff. Supervisors should work with inspection team members to reach agreement as the work. The team also should have a clear understanding of the purpose of the inspection. The standard for inspection planning is intended to ensure that appropriate care is given to selecting inspection topics and preparing to conduct each inspection, to include coordinating inspection work and avoiding duplication^[2].

Inspections should be organized around the business enterprise; that is, the various inspectorates should ideally coordinate their activities to ensure that all relevant risks are properly addressed. Inspection management systems are increasingly common in developed economies, although most are implemented within single agencies and one agency often has several systems in place for several processes^[3].

The inspection organization needs to ensure that the personnel conducting an inspection collectively have knowledge, skills, abilities, and experience necessary for the required assignment. Inspection organizations should have a process for recruitment, hiring, continuous development, and evaluation of staff to assist the organization in maintaining a workforce that has adequate. The nature, extent, and formality of the process will depend on various factors, such as the size of the inspection organization, its work, and its structure^[4].

3 Quality Vision for Automotive Process

Quality assurance and high-precision position detection systems for component handling applications are essential items in the automation engineering. Intelligent vision systems provide the key to higher productivity, greater efficiency and total quality assurance. The required precision and speed are achieved during production, and offer significant potential for enhancing the efficiency of automotive manufacturing. Vision systems must deliver 100% availability and reliability. There also

have to be user friendly and suitable for industrial environments. It takes a great deal of basic know-how and applications expertise to develop these machine vision systems [5]. Machine vision systems make an indispensable contribution throughout production. This starts early in the process, for example during stacking and unshackling of body parts exiting a press, which are then moved to a rack. In generally there are so many processes to check quality of the product such as stacking the body parts, parting removal, assembly of mounted parts, application of adhesive, gap alignment and flush mounting, body cavity protection, paint finish protection, installation of door seal and multiple final inspection.

If the requirement is zero defect quality, then manufacturing must assure that defect will not be produced in the first place. This mean that the process must be capable of the producing the required quality consistently and with a close to zero defect as possible. Manufacturing must do all it can improve the process to achieve this and then monitor the process to make sure it remain under control [6]. The goal of automotive manufacturing is to produce zero-defect cars that are correctly assembled. After the cars have passed through all of the process inspection stations, a final check is made at the end of the line. Integrated machine vision identifies items such as wheels, rims and type labels, checks that they are complete and properly installed and performs a plausibility check based on the model information [7].

4 SIP Station in Production Line

In the SIP station, all the production shops are under the control of the quality department in every major process. The press shop uses the way of sampling inspection, and other shops use the way of full-inspection in order to ensure the quality of the previous process. Once it finds quality problems, it needs to be checked forward and backward until repeated problems which are no longer found and the products are regarded as eligible. All the workshops have two inspection lines (A and B). All the workshops have to check their process quality with SIP and the products pass the qualified inspection will be sent to the inspection line to finish the final process. This process procedure for the SIP station shows in the figure.1.

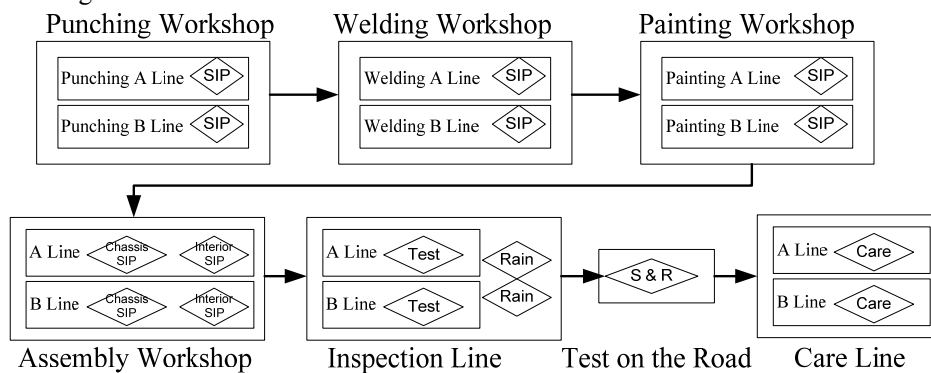

Figure 1 SIP Station in the Production Line

Table 1 Inspection Items of the SIP Station

Number of validation station	Name of validation station	Main item of inspection
V.S.#1	Press validation station	Surface quality of pressing
V.S.#2	Body validation station	Surface quality of body and other options
V.S.#3	Paint validation station	Surface quality of paint
V.S.#4	Internal decoration validation station of general assembly	Hardware of electrical appliance, harness, trim strip, matching of internal and external decoration, glass and so on
V.S.#5	General assembly chassis validation station	Hanging and fixing device, brake lines, inhaul cable, machine, harness, chassis layout, the strength of the door switch, scratch, and mechanical function
V.S.#6	General assembly validation station	Electrical system, engine compartment and clearance fit
V.S.#7	Inspection line validation station	Light, EFI system, emission, wheel alignment, rotation angle and braking force
V.S.#8	Inspection before receiving of customer	Function of electrical appliance and machine, missing parts and presentation quality

According to SIP process, SIP validation is mainly divided into eight stations. The following table shows all validation stations are checking their corresponding main item for each inspection.

5 SIP Information Flow Model

The major work of the SIP station include the inspection of the validation station, the feed forward and feedback of the quality information, the update of the information on the SIP message board, and the confirmation of repairing [8]. The inspectors of the validation station carry out the inspection according to the standardized operation sheet (SOS), recording defects, updating the SIP message board regularly, and forming the corresponding charts and reports about the quality defects according to the recorded data.

When validation station inspector finds quality problems, he will give an alarm according to SIP station, and fill in the relevant quality information in the “quality information board card” to feedback. When production shop receives the dark light signal of the validation station or “quality information board card”, the shop monitor will give feedback to the validation station to response to the problems immediately. Also the shop monitor will give respond the production line from quality validation station to check quality problem.

They should identify the vehicles or parts with quality problems and record problem breakpoint number. Then the shop monitor decide whether it can be repaired online according to the nature of problem. If it can be repaired online, they should immediately organize repairman to repair before quality validation station. If it cannot be repaired online, it should pass the quality validation station and repair offline. Inspector makes validation to the repaired vehicles or parts.

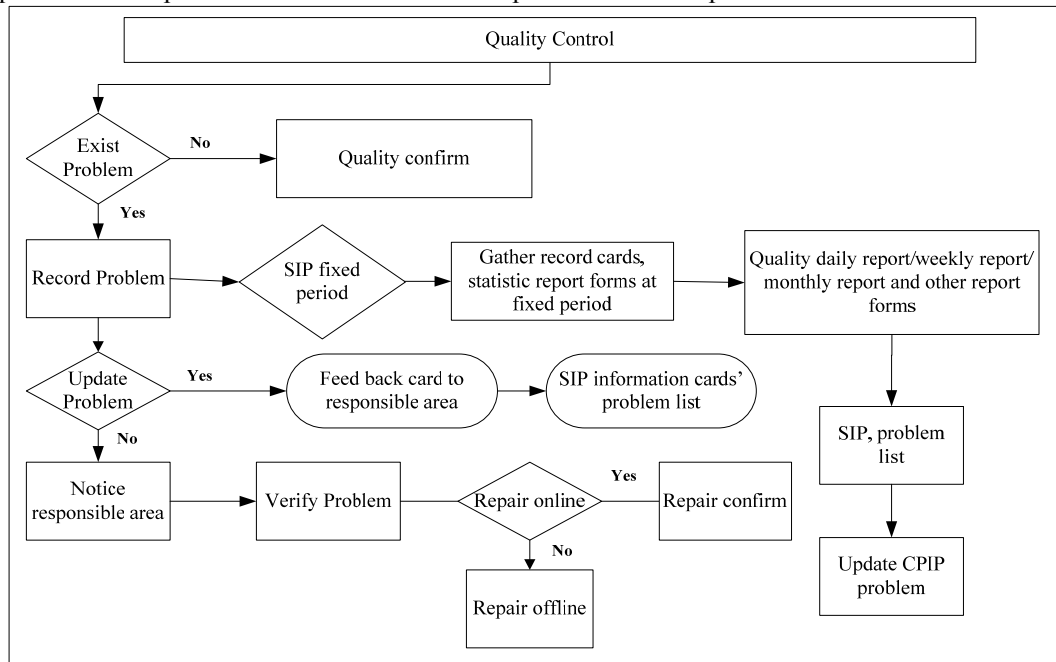

Figure 2 Standardized Inspection of SIP Station

Quality engineer analyses the data according to the inspection information recorded by the recording card, forming daily, weekly, monthly quality report, transferring information to each department. The quality daily report is divided into two parts: shop automobile type daily report and quality running daily report. Shop automobile type daily report mainly records daily quality information and analyzing the problems that affect first time quality, FTQ. Quality running daily report is summarizing and analyzing of quality information of this day, including running state and prior quality problem of FTQ. The quality weekly is divided into three parts: shop automobile type weekly report, SIP station internal weekly report and quality running weekly report. Shop automobile type weekly report is summarizing of quality problem of this week and recording the running state of FTQ and top-ten problems that affect FTQ. SIP station internal weekly report is summarizing of SIP stations quality data and communication among SIP stations. Quality running weekly report is summarizing the analyzing of quality information of this week including running state and prior quality problem of FTQ.

6 SIP Process Flow Model

SIP information flow is mainly divided into three parts: Data statistic and analysis, quality information alarm response and exchange of information of the validation station.

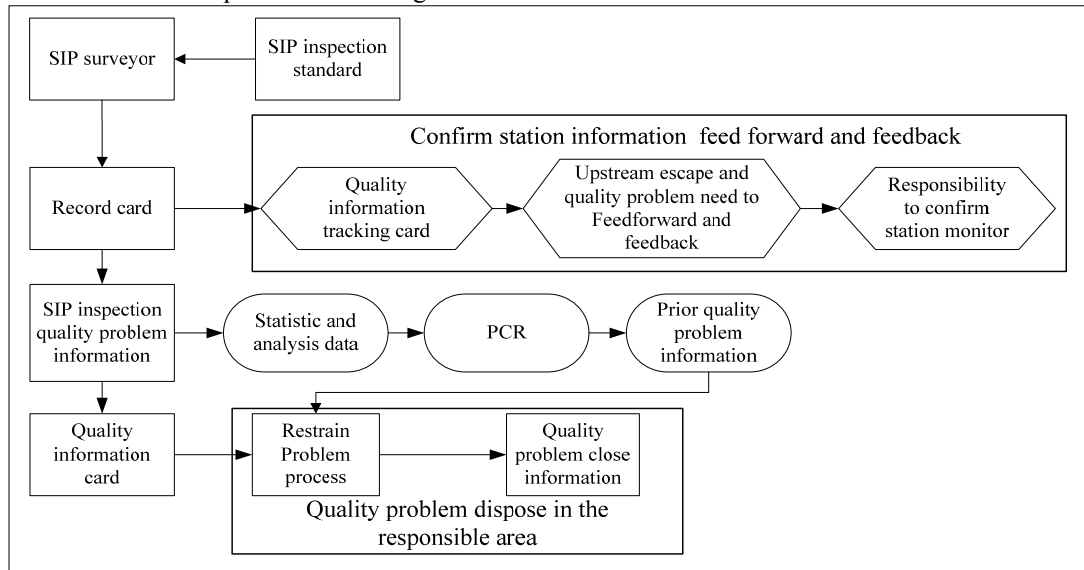

Figure 3 Process Flow in SIP Information

The surveyor gather information from SIP inspection standard station and record the problem information. The inspector from the record section analysis the problem record and send information to the confirm station to confirm quality information. SIP inspection station check some record problem according to statistic and analysis data and polymerase chain reaction PCR. Then quality engineer will send the result from that section to the quality problem dispose in the responsible area to finish checking quality information problem. The process flow of the SIP information is shown in Fig.3.

Specific to inspection work, inspectors should appropriately communicate information about the inspection process and the nature of the inspection to the various parties involved in the inspection to help them understand such things as the inspection objectives, time frames, data needs, and reporting. Inspectors should use their professional judgment and comply with their respective organization’s policies and procedures to determine the form, content, and frequency of communication. Communication should be appropriately documented in the associated inspection records.

7 Conclusions

The quality of work involve all departments, the efficiency of every post work and determines the products quality and service quality at the same time. However, it depends on the quality of people, including staff quality consciousness, responsibility and business level. The quality of information is the core of the entire company, quality management, corporate decision-making and quality improvement. Standard inspection process played a significant role in corporate decision making, information sharing and expert knowledge information platform. The standard inspection process can improve the quality of corporate governance in all aspects and product quality, accelerate the development of enterprises.

Research on Independent Brand System Strategy of Special Vehicle*

Wang Hui, Wu Yu

School of Management, Wuhan University of Technology, Wuhan, P. R. China, 430070
(E-mail: wanghui201312@163.com, meiyoyu1987@sina.com)

Abstract: The special vehicle plays an essential role in auto industry, and the independent brand of which dominates its future. This article focuses on the formation and building of independent brand system strategy of special vehicle. Firstly, it elaborates some basic concepts, then proposes two system strategy models according to the differences of brand number, brand hierarchy and brand portfolio in each brand system. Furthermore, the article analyzes the influencing factors in the process of independent brand system strategy implementation from three aspects.

Keyword: Special vehicle; Independent brand; Strategy; Influencing factor

1 Introduction

Special vehicle is one of the automobile products meeting special need in auto industry, which is equipped with special equipment and function, to undertake special transportation task or assignment. So it plays an important role in promoting the development of society and economy, as well as meeting the needs of people's living standard. Formulating independent brand strategy of special vehicle not only can make special vehicle industry stronger and bigger, but also can pull the regional economic rapid development. At present, there has formed rich theoretical achievements about brand strategy research by domestic and foreign scholars, such as single brand strategy and brand system strategy, and research has gone further to concentrate on brand equity and brand image. In summary, the research on vehicle independent brand has gradually risen by domestic scholars in recent years, but there are very few studies on special vehicle, not to mention special vehicle independent brand, which is nearly a blank.

2 Connotation of Special Vehicle Independent Brand

The concept of independent brand has two basic elements, one is independence, the other is brand. The former refers to full control and decisive power to brand from the perspective of intellectual property rights, meanwhile, the ability to make brand continuation effectively, which also means mastering the independent core technology to have the ability to decide and lead the future direction of the brand. Brand is a unique symbol or design, the difference between different brands lies in the comprehensive quality and feature of enterprise contained within the brand. So a brand is at least composed of four elements, namely graph, name, technology and commodity circulating in the market, especially for the last, represents the destination and carrier of other three.

Special vehicle independent brand is the collaborative product of such independent innovation ability, that are enterprise technology innovation, market innovation and management innovation. As the carrier of enterprise core competitiveness, special vehicle independent brand can make the enterprise gain market competitive advantage, as well as sustaining continuing growth.

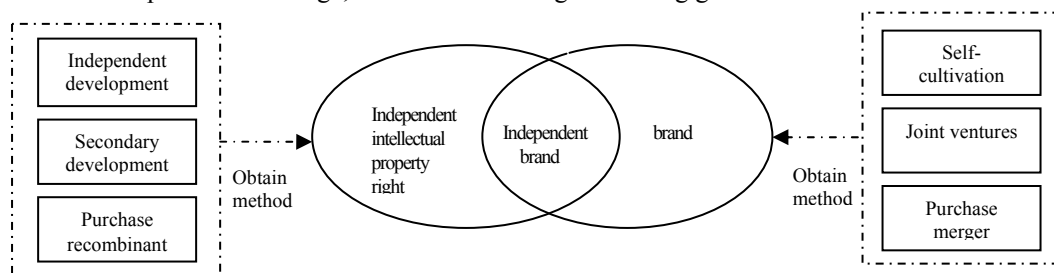

Figure 1 Independent Brand Component Model of Special Vehicle

3 Independent Brand System Strategy of Special Vehicle

From the viewpoint of system, independent brand system strategy implies that enterprise makes

* This paper is supported by enterprise commissioned project “Research on development strategy of special vehicle independent brand”, project number: 20112h0123.

best use of the resultant force produced by common characteristics of all brands to provide classification for a variety of products, thus achieves the optimal allocation of brand resources. Different from the single brand strategy, the choice of brand system strategy focuses on the relationship structure selection, such as the role and status of each brand.

In general, there are different brand number, brand hierarchy and brand portfolio in each brand system, so with two methods to divide brand system strategy model from different perspectives.

3.1 Strategy model of product brand and enterprise brand

According to the role and function in the system, there are mainly three kinds of strategy model in product brand and enterprise brand, model particularly in the former or latter and mixed mode, respectively.

Named by enterprise name, enterprise brand can convey the corporate business philosophy, culture, value and attitude to consumers, so as to form connection between different industries and integrate brand resources. Strategy model dominated by enterprise brand refers to that the corporate brand (parent brand) occupies the absolutely leading position in the system, which can influence each sub-brand and product, acting as the flag brand. Therefore, the relationship between parent brand and sub-brand presents as leading and supporting.

Figure 2 Figure of Strategy Model Dominated by Enterprise Brand

This model shows that enterprise brand can cover all products and services, which is mainly used in enterprise with less product variety and higher consumer homogeneity, so it's convenient for consumer cognition, and also conducive to form distinctive brand personality or strong brand influence, except for implementing strategic transformation.

In terms of product, product brand contains two meanings, one refers to the combination of product's name, term, sign, symbol, design and other fields, the other stands for a series of added value of products, including two aspects of interest point in function and psychology, such as that product can represent the utility, function, taste, form, price, convenience and service, etc, but that two have different connotations. Strategy model dominated by product brand means to give priority to product brand in the entire brand system, with complex correlation and interaction existing between different product brands.

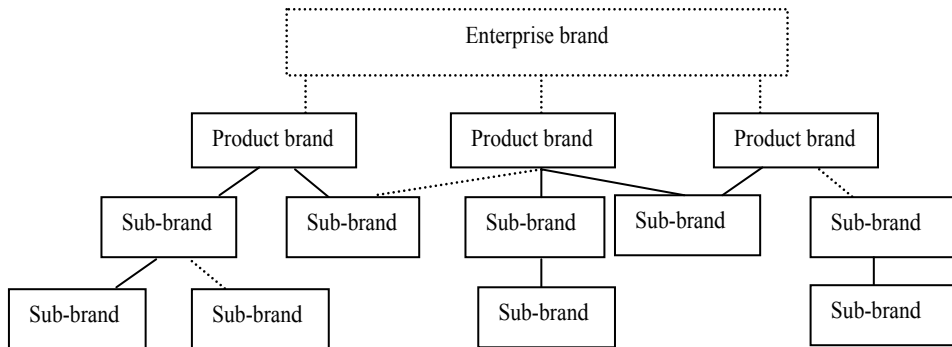

Figure 3 Figure of Strategy Model Dominated by Product Brand

The hybrid strategy pattern is mainly suitable for the more strong and complex enterprise with two major advantages. For one hand, it can give full play to the strong effect of corporate brand to make enterprise resources, corporate brand equity pass to each product brand through commanding its development and construction, which also provides protection for brand development. For the other hand, using this pattern can also seize the opportunity to expand some of the product brands rapidly to nurture the parent brand in turn, which promotes to form the benign interaction between them, and finally to realize the accumulation of intangible assets, as well as the sustained, rapid development of the

enterprise. However, the hybrid strategy requires huge fees, so must with a lot of continuable money as a guarantee.

3.2 Strategy model of core brand leading and multiple brands equal attention

According to the different proportion in the brand system, the brand system strategy model can also be divided into the core brand leading mode and multiple brands equal attention mode.

The core brand leading mode refers to that the special vehicle enterprise would focus on developing one or two brands in its brand system, with which to drive the development of other brands together. Such strategy can be used where brands have a wide difference and one or two brands stand more prominent at the same time. The choice of the core brand can either be the enterprise brand or the product brand, but both should occupy the absolute dominant position, and be far ahead of other brands in terms of brand influence or brand benefit. Moreover, it must play a significant role in the development trend and operation of the brand system.

The multiple brands equal attention mode is adapt to the special vehicle enterprise which chooses some brands with greater strength and more potential to form a pattern of multiple major brands covered and balanced development. But in the process of development, the special vehicle enterprise should pay attention to not overstating the number of brand, which may lead to the structure imbalance of brand system, as well as improper operation or management confusion.

4 Factors of Independent Brand System Strategy Implementation of Special Vehicle

It is a system engineering of long-term consideration on how to choose the suitable strategy mode for brand system of special vehicle enterprise. The enterprise should also more emphasis on the long-term development of brand system under the guarantee of current brand earnings. So there are three key factors influencing the strategic choice and implementation, the external environment, enterprise strength and brand features, respectively.

4.1 External environment

External environment conditions mainly include the economic environment, policy environment and industrial environment. The economic environment plays an important role on the brand development and brand awareness strengthening. Under different economic environments, the requirements for independent brand system strategy implementation are also different, which can ultimately boil down to the influence from social purchasing power to brand development strategy. But for special vehicle, due to its special purpose, the consumer groups are usually fixed and not primarily for individual, the impact is not significant on independent brand system strategy, such as the change of consumer income, spending or saving pattern, credit scale and so on. So when choosing the development mode, the enterprise should focus on competitor analysis, like that how many competitors exist, how the strength or resource advantage of the competitors are, what kind of brand strategy has been adopted, then to accurately positioning the market segments that can be developed or potential market that can be entered.

Government policy also stands significant position for independent brand system strategy. Especially for the special vehicle industry, it is very sensitive to the policy change, and a series of industry policy adjustment has made independent brands squealed. For example, the exit of preferential policies in purchasing vehicles in 2011, the implementation of the restrictions and the admittance of fuel consumption. At present, there is still too much restriction on private capital, so with lack of effective measures in independent research and development, as well as the independent brand construction.

Being the same as other industries, special vehicle industry would also go through four stages, namely formation, growth, maturity and decline. In different stages, consumer demand is different, as well as the competitive environment, not to mention the pattern of brand competition. Therefore, the emphasis and purpose of independent brand development strategy is also different, so with the different mode.

4.2 Enterprise strength

Enterprise strength conditions refer to the qualification enterprise owns when choosing independent brand development strategy, such as resource condition or cost effectiveness. The choosing strategy should be able to give full play to the enterprise's own resource advantage, optimize the resource allocation and reduce idle or waste resource, which should also be judged according to the actual situation of resource ability.

The management aim of enterprise is to obtain more profit and achieve better economic benefits.

The different choice of independent brand development strategy may lead to the different cost. So the special vehicle enterprise must make clear of the double degrees of brand system strategy under the target cost, which means the enterprise should consider the cost benefit ratio, and meanwhile follow the basic rule that income must be greater than cost.

In addition, the decision makers' own needs and values could also affect the choice of brand system strategy, not to mention the attitudes towards external environment or risk.

4.3 Brand features

The inherent characteristic of special vehicle independent brand mainly displays on its individuation, differentiation and distinctive culture. In the emotional benefits, individuation requires originality when designing the brand position and to win the consumer recognition. In the functional benefits, the character and function of brand must be consistent with the value and emotion of consumers.

Nowadays, in the special vehicle market, the phenomenon of product homogeneity is very serious, so the independent brand development strategy selected should be able to strengthen the externalization of the product intrinsic value, and make the differentiation characteristics of the brand clear and prominent in front of consumers to attract attention. In general, differentiation is mainly manifested in these fields of brand, such as the beauty, convenience, comfort, price, service or benefit, besides, for the special vehicle independent brand, the functions of safety, environmental protection and energy saving should also be considered seriously. In fact, an enterprise can't highlight its difference in many ways with its competitors, but it must stay ahead in a particular aspect to gain better market advantage from such difference.

The core value of the brand culture is the main part of the brand value, so the special vehicle enterprise should concern about the refining of national characteristics or distinct cultural elements to enhance the affinity of independent brand.

5 Conclusion

Special vehicle independent brand is the collaborative product of independent innovation ability, which decides the market competitiveness of enterprise. According to different perspectives, such as the position, function or proportion brand holds, the independent brand system strategy can be divided into two modes, the strategy model of product brand and enterprise brand, as well as the strategy model of core brand leading and multiple brands equal attention. At last, this article proposes that there are three key factors influencing the strategic choice and implementation, the external environment, enterprise strength and brand features, respectively.

Study on the Influence of Science and Technology Innovation on International Service Outsourcing in Jilin Province of China*

Liu Liqin, Liu Xiaohui

School of Business Administration, Changchun University of Technology, Changchun, P.R.China,
130012

(E-mail: liuliqin2002@xinhuanet.com, 51975844@qq.com)

Abstract: This paper firstly analyzes the status of science technology innovation in Jilin Province of China. The input of science and technology innovation is increasing, the institutional guaranty is perfecting, the service system is growing, and the science and technology innovation ability in Jilin Province of China is rising while which is weak in China. Science and technology innovation can affect the ability to undertake international service outsourcing, the human resource quality, the upgrading of service outsourcing industry, the research and development ability in software, and the building of service outsourcing base. In order to accelerate the technology innovation ability of international service outsourcing in Jilin province of China, some measures should be taken to play fully the function of innovative department, to optimize the environment of science and technology innovation, and to perfect the mechanism of the science and technology innovation.

Key words: International service outsourcing; Science and technology innovation; Jilin Province of China

1 Introduction

With the development of the international service outsourcing, many scholars studied the relation of international service outsourcing and science and technology.

First, some scholars studied the effect of developing international service outsourcing on the technology progress of undertaking country. Yu Meici (2008), Zhang Wang (2010) discusses the technology spillover effects of international service outsourcing by developing a model of endogenous technical progress that increases varieties of intermediate inputs. Through the competitive equilibrium analysis, the conclusion is drawn that the technology spillover derived from outsourcing exerts positive effects on the technology growth of the undertaking country.

Second, some scholars studied the influence of developing international service outsourcing on the ability to technology innovation of the enterprises. Bartel (2001) thought the influence is negative. Bartel indicated that ITO can promote the technology transformation of the contracting-out party. However the invisible feature of service will increase the contradictions between the parties of service outsourcing and developing international service outsourcing can hinder the technology innovation of the enterprises. Cui Ping (2010) proved the influence is positive. Cui Ping used the panel data of China's IT listed companies to make an empirical analysis of the impact of undertaking service outsourcing on the technological innovation of enterprises. The result shows that the technological inputs and outputs of enterprises undertaking international outsourcing are significantly higher than those which have not undertaken.

Third, some scholars studied the influence of regional science and technology development on undertaking international service outsourcing. Miozz (2001) studied the international service from the view of technology with the method of "two-divisive doctrine", the result showed that with the development of national economic, technology progress can affect the technology intensive industry contract out their service activities. Zhu Shengyong and Li Wenxiu (2009) analyzed the influencing factors based on OECD Countries' input-output data. It shows that some factors play a positive role in service outsourcing and information technology is one of the factors.

According to studying the literates, it finds that a few scholars studied the influence of regional science and technology innovation on the development of international service outsourcing with the qualitative analysis. This paper studies the influence of science and technology innovative on the development of international service outsourcing in Jilin province of China.

* This paper is supported by the Science and Technology Department of Jilin Province Soft Science Research Project (issue No. 20120642)

2 the Status of Science Technology Innovation in Jilin Province of China

2.1 The input of science and technology innovation is increasing

The persons engaged in R&D are the key element in the science and technology innovation. The persons in R&D department, the Full-time Equivalent of R&D personnel and the person with high educational background are increasing in Jilin province of China from 2009 to 2011(See table 1). Proportion of persons with high educational background to the whole R&D personnel is 70%, which shows the quality of the persons taking part in science and technology innovation is good.

The Intramural Expenditure for science and technology is rising in Jilin province of China from 2009 to 2011(See table 1). The rising tendency is obviously of expenditure on R&D and local government intramural expenditure, the expenditure on new products development is decreased in 2010 while increased remarkably in 2011. The plenty of Expenditure input build the economic guarantee to science and technology innovation.

Table 1 The Input of Science and Technology in Jilin Province of China

index	2009 year	2010 year	2011 year
R&D personnel (person)	56428	65380	70704
Full-time Equivalent of R&D personnel (man-years)	31457	34115	38904
Person with doctorate (person)	6725	6980	7794
Person with postgraduate degree (person)	13121	15101	16934
Person with undergraduate degree (person)	19444	21337	24892
Proportion of persons with high educational background to the whole R&D personnel (%)	69.6	66.4	70.2
Expenditure on R&D (10 000 yuan)	306229	355405	488723
Local Government Intramural Expenditure(million yuan)	18.98	19.12	21.18
Expenditure on New Products Development(10 000yuan)	331990	219809	709348

<China statistical yearbook> 2010~2011, <China statistical yearbook on science and technology 2012 >

2.2 The guarantee mechanism of science and technology innovation is perfecting

A series of laws and regulations are built in Jilin province of China such as <the decision of implement the strategy of developing science and education to promote province improvement >, <the decision on strengthening technology innovation to develop the high science and technology industry >, <the decision on deepening the reform of science and technology system>, <the regulation of promoting the development of science and technology enterprise>. The laws and regulations involve input of science and technology, intellectual property protection, the environment of science and technology innovation, which guarantee the science and technology innovation.

2.3 The service system of science and technology is rising

The service organizations are established in Jilin province of China to promote the development of science and technology innovation. The economic information centre of Jilin province of China was built in 1989, which is the first department to service the science and technology innovation. There are 12 technical markets, 38 productivity development centers and 14 technical incubators. All the service organizations reform a service system of science and technology innovation, and play an important role in the transformation of science and technology into productivity, communication of technical information and introducing technology. The service organizations have brought 1500 technical enterprises and 2000 technical items. The technical innovative center of high-tech zone in Changchun is awarded the excellent national innovative center.

2.4 The technology innovation ability is strengthening

Table 2 The Level of Technology Output in Jilin Province of China

	Transaction Value in Technical Market (10000yuan)	Number of Inventions Patents Application Granted (piece)	income of software technical service(10000yuan)
2007	174845	2855	288000
2008	196066	2983	347300
2009	197598	3275	455500
2010	188090	4343	480000
2011	262614	4920	530000

Transaction value in technical market, number of inventions patents application granted and income of software technical service is rising, which shows the technology innovation ability is strengthening in Jilin province of China (See table 2).

3 The Influence of Science and Technology Innovation on International Service Outsourcing in Jilin Province of China

3.1 The influence on the ability to undertake international service outsourcing

Service outsourcing industry is technology - intensive industry, especially the development of ITO and KPO demand more input of science and technology. Only those enterprises with high-technology can engage in the international service outsourcing. Science and technology innovation can promote the development of high-technology and strength the ability to undertake the international service outsourcing.

With the development of science and technology, the international service outsourcing undertaken is increasing in Jilin province of China. In 2011, the amount of contractual offshoring service outsourcing is 35696 thousand dollars, which increased 42.4% than 2010; the amount of implement is 22398 thousand dollars, which increased 38.3% than 2010. In 2012, the amount of offshoring service outsourcing more than which in 2011. In 2012, there are 59 enterprises to undertake the international service outsourcing in Jilin province of China.

3.2 The influence on human resource quality

International service outsourcing needs human resources with high quality. The technical talents with service technology, software technology and other technology related the industry is the key element in international service outsourcing, and the administrators can communicate effectively with the clients which compounded basic technology of service outsourcing, ability to forecasting industry development and ability to manage modern enterprises. The science and technology innovation is done by the human resource, and the process of science and technology innovation is also the process of increasing human resource technical ability. The result of science and technology innovation is grasped firstly by the human resource.

Science and technology innovation increases the quality of human resource in Jilin province of China. The patent and the technical thesis can evaluate the human resource quality. Table 2 shows that the patent in Jilin province of China is increasing year by year. Besides, 994 book and 27672 technical papers were published in 2009. The quantity of book publish in 2009 is 1.6 times which in 2000 and the quantity of papers publish in 2009 is 2.4 times which in 2000.

3.3 The influence on upgrading service outsourcing industry

International service outsourcing consists of information technology outsourcing (ITO), business process outsourcing (BPO) and knowledge process outsourcing (KPO). The degree of technology-intensive in BPO is higher than which in ITO and the degree of technology-intensive in KPO is higher than which in BPO. The science and technology innovation can improve the science and technology level of enterprise, so the enterprises with the ability to science and technology innovation can undertake not only ITO but also BPO and KPO.

With the science and technology innovation, the amount of BPO and KPO is increased gradually in Jilin province of China. The proportion of BPO to all the service outsourcing in Jilin province of China is 11% and the proportion of KPO is 7% in 2011. The proportion of BPO to all the service outsourcing in Jilin province of China is 12.5% and the proportion of KPO is 7.5% in 2012. The data show that service outsourcing industry in Jilin province of China is upgrading gradually.

3.4 The influence on research and development ability in software

There are 877 software enterprises and lots of scientific research institutions in Jilin province of China. All the scientific research departments pay more attention to science and technology innovation and increase the research and development ability in software. Jilin province of China developed and produced 800 software products, in which there are 511 products owning independent intellectual properties right. The technical level of some products is advanced in China. About 20 items such as the software managing population of Changchun Hongda enterprise, the software managing manufacturing enterprises of Qiming information technology co., LTD, the information security software of JIT Cinas, the management software of Jilin golden hawk enterprise, are awarded the good software in China, and the market share is better than other software.

3.5 The influence on building of service outsourcing base

Science and technology innovation is the important method of gaining persistent competitiveness for the enterprises of service outsourcing. The enterprises should operate on other enterprises so that they can use the overflowed technology and strengthen the ability to innovate. Industrial agglomeration becomes the important condition for science and technology innovation. More and more enterprises of service outsourcing settle down industrial park, which accelerate the development of service outsourcing base.

Changchun Software Park, Jilin Software Park and Sino – ROK Software Park in Yanji are the chief service outsourcing base in Jilin province of China. Changchun Software Park is biggest service outsourcing base in Jilin province of China. The products about Network security and information security such as biometric identification, electronic certification and distance education are developed principally in Changchun Software Park. Embedded software and application software are developed principally in Jilin Software Park. Jilin Software Park has established strategic partnership with some enterprises coming Japan, America and Europe. Sino – ROK Software Park in Yanji undertakes the software outsourcing and information outsourcing coming Japan and ROK. The amount of service outsourcing industry, number of enterprises and employees in service outsourcing industry increased. (See table 3)

Table 3 The Development of Service Outsourcing Industry in Changchun Software Park, Jilin Software Park and Sino – ROK Software Park in Yanji

index	Changchun city	Jilin city	Yanbian region
Executive amount of service outsourcing (100 million yuan)	12.9	0.37	0.36
Executive amount of offshoring service outsourcing (10 thousand dollar)	1756.8	79.0	404.0
Number of enterprise undertaking actually service outsourcing (item)	24	3	17
Person engaged in service outsourcing (person)	7483	265	1260

4 The Suggestion of Improving the Ability to Acience and Technology Innovation

4.1 The function of innovative department should be played fully

The science and technology innovative departments consist of enterprises, research organizations and universities. The enterprises should be the most principle innovative department, the research organizations and universities should take the paramilitary duties, and government should service for the science and technology innovation. The competitive of research organizations and universities in Jilin province of China is at the middle level in China. The enterprises undertaking international service outsourcing is lagged, the number and scale of the enterprise are small, and there is only one enterprise in Jilin province of China of the 100 software enterprise listed among China. The talent and expenditure input in science and technology innovation is small. The enterprises of service outsourcing should be supported by capital and policy. Anyway, the enterprises, research organizations and universities should pay more attention to their research and enhance their ability to science and technology innovation.

4.2 The environment of science and technology innovation should be optimized

The innovation is affected directly or indirectly by the environment of innovation. The information infrastructure such as internet and telecommunication network should be strengthened and which can support a credit information technical panel for science and technology innovation. Plenty of talent and capital should be input to service outsourcing industry, research instruments should be equipped, the communication and cooperation with different regional technical department, high-tech enterprise should be strengthened, which can build the technical environment for innovation. The software industry, the industrial chain which consists of telecommunication industry and Service industry should be developed and the Alliance of service outsourcing industry should be boosted, which can establish the industrial environment for innovation. Besides, government should manage good market environment for science and technology innovation.

4.3 The mechanism of the science and technology innovation should be perfected.

The technology innovative input mechanism should be formed which is comprised with governments, enterprises, financial institutions and members of the public. The capital should be raise by many channels, and human capital can be not only cultured at home but also introduced at abroad.

The transformation platform of technology achievement should be established and the transformation mechanism should be development with the influence of market mechanism. The stimulation mechanism should be development which consists of money and job award; the research organizations, universities and the research persons should be encourage transforming their research theories into products. The government should promote the cooperation of enterprise, research organizations and universities support the innovative enterprises to transform their research achievement to products with capital, credibility, and guarantee.

5 Conclusion

Science and technology innovation can affect the development of international service outsourcing by the way of affecting the ability to undertake international service outsourcing, the human resource quality, the upgrading of service outsourcing industry, the research and development ability in software, the building of service outsourcing base. It is essential for Jilin province of China to play fully the function of innovative department, to optimize the environment of science and technology innovation, and to perfect the mechanism of the science and technology innovation so that accelerate the science and technology innovation of international service outsourcing in Jilin province of China.

Research on the Endogenetic Impetus of Strategic Emerging Industrial Cluster Development

Jiang Wei, Diao Zhaofeng

School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070

(E-mail: diaozf@163.com, dzhaof@whut.edu.cn)

Abstract: The strategic emerging industrial cluster is an advanced industrial cluster. Its proximity is not separate from industrial cluster. On the contrary, it is rooted in the internal structure and interactions of the industrial cluster. In this paper, the proximity perspective is used, especially the perspective of how the geographical proximity affects the knowledge flow of the cluster, collective learning and innovation, thus promoting the development of the cluster. The endogenetic impetus mechanism of strategic emerging industrial cluster development endogenetic impetus is analyzed.

Key words: Strategic Emerging Industry; Industrial Cluster; Development Impetus

1 Introduction

Strategic emerging industry refers to the emerging industry that has the strategic significance on technological innovation, optimization and upgrading of industrial structure and the coordinated development of national economic and social stability. These industries has the characteristics of intensive innovation elements such as knowledge and technology, high investment risk with long period, internationalization development, and fierce international competition. Therefore, the formation and development of strategic emerging industrial cluster has its endogenetic impetus and mechanism. Its endogenetic impetus has the market self-organizational characteristics, which have direct and fundamental impact on the development and evolution of clusters. As the strategic emerging industrial cluster is an advanced industrial cluster, the industrial cluster impetus itself is the development impetus, especially in the area of specialized diversion of labor, transaction cost, external economies and economies of scale, etc. The proximity of strategic emerging industrial cluster is not separate from industrial cluster. On the contrary, it is rooted in the internal structure and interactions of the participants within the industrial cluster. The following is the research on how the geographical proximity affects the knowledge flow of the cluster, collective learning and innovation, thus promoting the development of the cluster with proximity perspective.

2 Meaning and Characteristics of Proximity

Proximity, also can be described as accessibility, refers to the same or similar characteristics of “group” among different subject in the same network. By summing up the relevant regional economic geography literature, proximity can be divided into three types: industrial proximity, social proximity and geographical proximity.

Among these three different types, geographical proximity concept is relatively simple, which means the proximity in space among the innovation subjects in regional economic. That will make sure of the smooth interaction between the innovation subjects despite the barrier of distance. According to Joseph Alois Schumpeter, innovation is not an isolated space, and it is not equally distributed in time and space, but tends to be cluster. Besides, innovation is not equally distributed in the entire economic system, but tends to be accumulated in some department. After Joseph Alois Schumpeter, lots of scholars proved that innovation activity, like other production activities, has a strong geographic aggregation characteristic.

The connotation of social proximity is relatively abundant, and it is easier to generate ambiguous. Social proximity is closely related to the concept of social embeddedness. Granovetter pointed out that behavior and instruction are closely linked. People’s economic behavior and social behavior are deeply embedded into the institutional environment and social culture. Social proximity mainly reflects the impact the economic behavior of innovation subjects have on the entire network structure and the interaction among individuals. Namely, social proximity can be divided into cultural proximity, institutional proximity and organizational proximity.

As to industrial proximity, it means that the subjects use the same or similar process, means of production to produce the identical production, which leads to horizontal competition. At the same time, the enterprises are at different stages of industrial chain, which leads to vertical cooperation.

Proximity can be divided into five types^[1], the meaning and characteristics of each type are shown in Table 1.

Table 1 Meaning and Characteristics of Each Type of Proximity

type of proximity		Main dimensions	Too little proximity	Too much proximity	Possible solution
Geographical proximity		distance	No spatial externality	Lack of geographical openness	Combine self-sowing with external relation
Social proximity	organization	control	opportunism	bureaucracy	Loose contact network
	cultural	trust (based on social relations)	opportunism	Lack of economic rationality	Combine embedness and market relation
	institution	trust (based on mutual institution)	opportunism	Locking and inertia	Check and balance of institutional system
Industrial proximity		Knowledge gap	misunderstanding	No source of innovation	Mutual knowledge base based on diversity and complimentary

3 Inherent Logic Between Geographical Proximity and Industrial Cluster

In the knowledge economy era, knowledge has replaced capital as the resource with the most strategic value and development potential. Knowledge is obtained by using innovation and is mastered by learning. Therefore, innovation has become the most important driving force in economic development, learning the most important approach. The development core of industrial cluster is whether it has lasting innovation capability within the cluster in this knowledge economy era. The innovation capability within the cluster has a close relation to the mutual learning of the participants as well as the flow of knowledge among all the subjects. In addition, geographical proximity has provided convenience for the participants to learn and exchange. Therefore, in the process of industrial cluster innovation, geographical proximity has a significant role. Neoinstitutional economics mentioned the concept of transaction cost, which has a significant meaning in explain the relation between cluster development and geographical proximity. Coase, the presenter of transaction cost theory, believed that enterprises gathering in a certain area have the geographical proximity, which provide convenience for exchanges and reduce information asymmetric and opportunism in transaction. In addition, it reduces the time and cost in seeking market information, as well as the transaction cost of two trading parties^[2].

In summary, we can see that there are inherent logic between geographical proximity and industrial cluster, as shown in Figure 1.

		enterprise	
		trustworthy	not trustworthy
customer	buy	100,100	50,150
	do not buy	0,0	0,0

Figure 1 Inherent Logic Between Geographical Proximity and Industrial Cluster

4 Mechanism of Geographical Proximity in Industrial Cluster

Geographical proximity, social proximity and industrial proximity are inseparable and interconnected. Generally speaking, the relational network will not work well in interaction and exchange with only one proximity. For example, knowledge network is an integration of several different proximity, and show different features. In practice, the knowledge network of mutual cooperation can be formed with only geographical proximity and social proximity, but no industrial proximity in a certain area. However, the network is relatively loose. If there is only geographical proximity and industrial proximity, but no social proximity, the network will have a shortage of interaction and innovation. If there are only industrial proximity and social proximity, but no geographical proximity (for example, international scientists association, etc), this kind of organizational

network has a strong leading value and professional characteristics. It is another form of interaction network. Unlike the three kinds of network above, strategic emerging industrial cluster contains geographical proximity, social proximity and industrial proximity at the same time. Its proximity is not separate from industrial cluster. On the contrary, it is rooted in the internal structure and behavior of the industrial cluster. Therefore, strategic emerging industrial cluster has more efficient knowledge exchange and learning network. Figure 2 shows how geographical proximity, social proximity and industrial proximity are combined to promote the new network of strategic emerging industrial cluster and how the dynamic competitive advantage is obtained from them.

At the same time, it must be noted that when the proximity exceeds a certain limit, it may bring some risks to industrial cluster, such as vulnerability, locking and fossilization, and then lead to the invalidation of impetus mechanism in the industrial cluster [3]. In addition, from the perspective of knowledge, excessive proximity may lead to assimilation of the subjects in the industrial cluster, while too little proximity will lead to difficulty exchange of knowledge. Knowledge, too new (not easy to take in or digest) or too old, is meaningless for innovation. So, in practice, we should not only attach importance to the integration with local culture in developing strategic emerging industrial cluster and keep local embeddedness, but also enhance compatibility and maintain openness in the cluster.

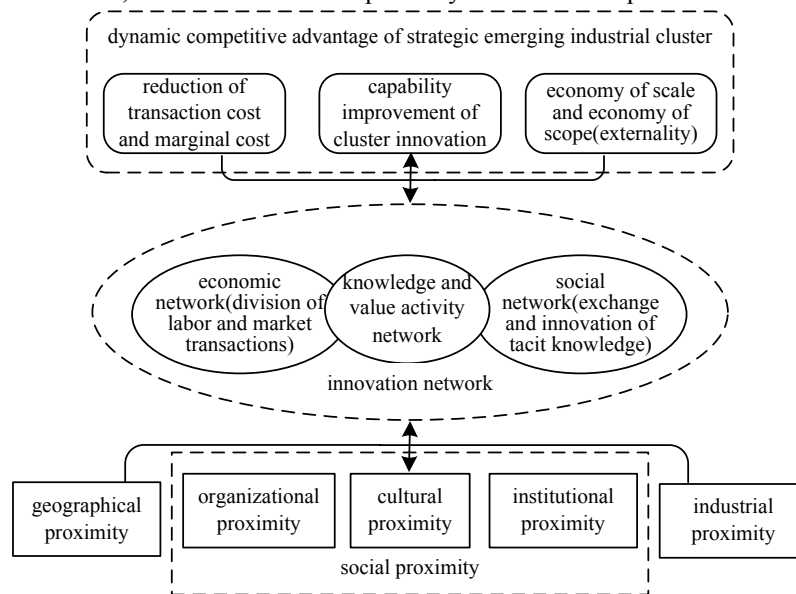

Figure 2 Industrial Cluster Innovation Advantage Constructed by the Combination of Proximity and Network Interaction

5 conclusion

Proximity refers to the same or similar characteristics of “group” among different subject in the same network. The formation and development of strategic emerging industrial cluster are accompanied by three formation of proximity: geographical proximity, social proximity and industrial proximity. Its proximity is not separate from industrial cluster. On the contrary, it is rooted in the internal structure and interactions of the industrial cluster. Therefore, strategic emerging industrial cluster has more efficient knowledge exchange and learning network. Geographical proximity, social proximity and industrial proximity are combined to be the internal impetus of new network of strategic emerging industrial cluster.

Abstract: In the context of global climate change and low carbon economy, Chinese petrochemical industry is under increasingly great pressure of CO₂ emission reduction and social responsibilities, and meanwhile, facing severe challenges including oil shortage, poor oil quality, and product standard upgrade. The paper argues that currently it is practical for the industry to focus on improving energy efficiency and clean energy structure, and integrated innovation should be the proper strategy choice for Chinese petrochemical industry. Some implementation approaches are discussed as followed: integrating current refining technology and low carbon technology, integrating innovative process and innovation organizations, and establishing strategic alliance of low carbon technology innovation. Besides, Clean Development Mechanism is suggested to be highlighted for international collaboration.

Key words: Petrochemical Industry; Low Carbon Technology; Technology Innovation; Integrated Innovation; Strategy Alliance

1 Introduction

Climate Change, especially global warming, has become one of the most significant environment and development challenges to human society in 21st century. IPCC (2007) argues that most of the global warming is the consequence of human activities with a probability of 90%, in particular from the greenhouse gases emissions due to the use of fossil fuels^[1]. Petrochemical industry refers to the industry of oil refining and the chemical enterprises with materials of oil and gas. As one of energy intensive industries, the productive process of petrochemical industry needs to consume lots of fossil energy. Combustion emission is the largest CO₂ emission source, and followed by process drain. There are some indexes that have significant impacts on CO₂ emissions, including the scale of petrochemical corporate, quality of crude oil, standard of refined oil products, depth of processing, and the level of equipment and management. Since the pressure of emission reduction on developed countries from Kyoto Protocol, international oil corporations, including BP, Shell, and Exxon Mobil, all pay great attention to CO₂ emission reduction, aiming to maintain their environmental protection responsibility and establish their green images by developing low-carbon technologies, and finally grasp the initiative of low carbon energy technology development in the future. Generally speaking, the development of low carbon technology mainly focus on four fields: improving energy and oil processing efficiency; exploiting renewable energy; developing CO₂ capture and storage technology (CCS); developing CO₂ isolation and utilization technology^[2-3].

Since current China is in the process of industrialization led by heavy chemical industry, the petrochemical industry plays key roles in supplying fundamental energy and chemical materials, and meanwhile, acts as both of major energy customer and CO₂ emission resource. In the context of global actions to deal with climate change, Chinese government has claimed the target of CO₂ emission reduction in economic and social development plans, of which the petrochemical industry has to undertake great pressure and responsibilities to reduce greenhouse gas emission and provide low-carbon energy on premise of ensuring national energy supply. Since technology innovation is proved as an effective method to alleviate and adapt climate change^[4], the paper selects the issue of low carbon technology innovation and discuss the strategy choices for Chinese petrochemical industry to deal with the dual pressure of CO₂ emission reduction and sustainable development. On the basis of analysis on the challenges and opportunities, the paper argues that Chinese petrochemical industry must be based on the national conditions, aim to integrate energy conservation, emission reduction and industries renovation through technology innovation, and finally coordinate the development of society, environment and industry.

* The paper is supported by "Fundamental Research Funds for the Central Universities" (10CX05004B), "Soft Science Program of Shandong" (2013RKE28003) and "Soft Science Program of Qingdao" (12-1-3-84-(9)-zhc).

2 Challenges to Chinese Petrochemical Industry

2.1 Pressure of CO₂ emission reduction from governments and public

With rapid growth of economic aggregate, accompanying influences of low energy efficiency and constraints of energy structure, China's total amount of greenhouse gas emission increases rapidly, and Chinese government shoulders double pressure from both the deterioration of domestic ecological environment and the international standard of emission reduction. In 2009, China has promised that the CO₂ emission of per-unit GDP will fall by 40-45% in 2020 than 2005. Petroleum & Chemical Industry "Twelfth Five-Year Plan" Development Guide also claimed that the expenditure of energy and the gross of CO₂ emission for every 10 thousand RMB worth of industrial value added should drop by 15% in 2015 than "Eleventh Five-Year Plan". So it is the only way for petrochemical industry to transform the economic development mode and take the road of sustainable development by cutting down CO₂ emission and providing low-carbon energy.

2.2 Increasing foreign-trade dependence of crude oil

Comparing with petroleum refinery distillation capacity of 540 million tons per year and ethylene production capacity of 15.365 million tons per year in 2011, the gap of crude oil output is tremendous steady on about 200 million tons per year [5]. In 2012, China's crude oil imports reached up to 270 million tons, accounting for 56.4%, more than 50% of the security cordon. Domestic oil demand in 2020 is expected to 600 million tons and the foreign-trade dependence is going up to 68%, which is close to a high-risk line of 70%. Short supply and continuous high price of crude oil directly affect the stable operation and the sustainable development of the petroleum refining industry in China, and also constitute serious and urgent threats to national security. As a pressing issue of the petrochemical industry, it is instant to improve energy efficiency, which means to turn limited resources into energy and petrochemicals needed for economic development.

2.3 Inferior and Heavy Properties of Crude Oil

Petroleum, a non-renewable fossil energy, is harder to explore and develop around the world among which the output of accessible low-sulfur and light crude oil decreases constantly, while the proportion of sulfur-bearing and heavy crude increases by years [5]. Consequently, of scanty domestic petroleum resources, the scale of new exploitable hypotonic and extremely-viscous reserve is increasing, which leads to greater processing difficulty. To follow the trend, the refinery process and technology of petrochemical industry is required to be improved, and the deeper processing of raw materials and stronger adaptive capacity of equipments are also needed. However, with the growing complexity, severity, costing and energy consumption of oil refining, the intensity and gross of carbon emission will be inevitable to increase as a sequence.

2.4 Clean products for environmental protection

Because of enormous pressure of environment protection around the whole world, it's instant to reduce exhaust gas emission to prevent air pollution by upgrading qualities of products, including fuel oil. As a result of the frequent haze across China in recent years, with great tension from the government and the public, Environmental Protection Department regulated the environmental index and the clean ability of vehicle fuel oil more rigorously. That is to say, domestic gasoline and diesel standards keep going on, which will bring much more cost pressure to the petrochemical industry for its quality upgrading. It is worth noting that future development tendency will follow the Low Carbon Fuel Standard established by the US and Europe, concerning low carbon of clean fuel.

3 Strategic Analysis of Low Carbon Technology Innovation

3.1 Strategic framework of technology innovation

When Chinese petrochemical industry makes strategies of low carbon technology innovation, it must take all factors into consideration, including challenges from international and domestic economic society, key points and thoughts of national development and reform, and its own strategies and sustainable development, so as to offer energy security to maintain China's stable and fast economic growth. Meanwhile, Chinese petrochemical industry should pay close attention to major breakthroughs of industrial key generic technology and the disruptive innovation which bring deeply influence on the industry. Neither independent innovation nor simulating innovation matches the maturity, technology level and targets of the present Chinese petrochemical industry.

According to the change degree of product and process, the Research & Development Projects of any industry or enterprise can be divided into four types ^[6]: derivative projects, platform projects, breakthrough projects and research and advanced development projects, as shown Fig 1. Different types

of R&D project needs different strategy and investment. However, in long run, the industry must evaluate and develop current core technology, and plan radical innovation and foresight innovation for its sustainable development. Therefore, the paper suggests Chinese petrochemical industry to develop low carbon technology with an integrated and systemic view.

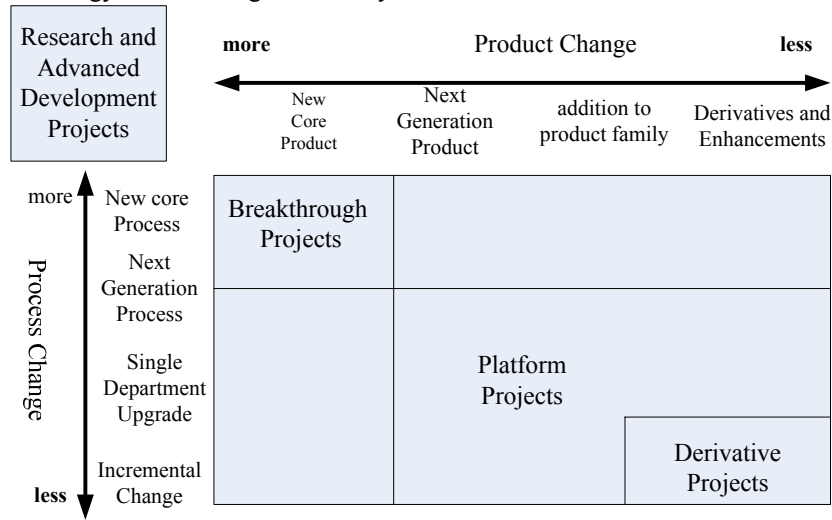

Figure 1 A Theoretical Framework of R&D Projects

3.2 Integrated innovation strategy of chinese petrochemical industry

As Tidd (2005) argues: If our mental models are limited, then our approach to managing is also likely to be limited [7]. Due to globalization and integrated trends of Science and technology, the former linear model, technology push or market pull, has not adapted to the changing context. So new models of innovation process, like coupled innovation, interactive innovation, and system & network innovation, have been introduced and applied in the past years [8]. This paper adopts integrated innovation to explain the strategy choice for Chinese petrochemical industry to develop low carbon technology.

The concept of integrated innovation is introduced by Macro Iansiti (1998) who developed former research of Freeman, Dosi, Nelson, and Rothwell [9]. Integrated innovation could be not only illustrated with a framework of technology integration, knowledge integration and organization integration, but also considered as a complex system concerning technology, knowledge, strategy and organization levels. Choosing and implementing the strategy of integrated innovation will help the petrochemical industry to achieve the match and integration of strategy, technology, knowledge, organization and process, deal with the competition of technology and market in the uncertain condition, strengthen the core competence of enterprises, consolidate and improve the sustainable competitive advantage of enterprises.

CO₂ emission reduction of the petrochemical industry is a global systems engineering which needs foreign advanced experiences for reference and overall consideration about technical feasibility, economic effectiveness and social responsibilities, and involves various aspects, such as producing, technology, technique, equipment, management, marketing, and so on. In order to choose a proper low-carbon technology development direction, one should compare emission reducing potential and advancement, and comprehensively analyze indexes of technology potential and economic maturity. In addition, it is equally important to control China's emissions of greenhouse gases and with an eye to provide sufficient green low-carbon source for the country.

4 Implementation Approaches of Integrated Innovation Strategy

4.1 Integrating current refining technology and low carbon technology

With the acceleration of industrialization and urbanization, China asks for more sufficient and cleaner energy and chemical materials. It is expected that the current energy structure dominated by fossil fuels won't take a fundamental change in following two decades, and the capacity of oil refining and ethylene production will increase steadily as well. That means in the context of the sustainable and stable growth of the national economy, CO₂ emission reduction of petrochemical industry does not mean to compress the scale of production, and developing low carbon technology can't exclude mainstream

refining technology. Low-carbon technology innovation should be based on current refining technology rather than one-sided emphasis on developing so-called pure low carbon technology. The idea insisting on the green and low-carbon principles of promoting Chinese refining industry is in consonant with China's national conditions [6]. Nowadays Chinese petrochemical industry should focus on the following: utilization technology for resource, upgrading technology of refined oil quality, environment-friendly refining technology, energy saving technology of refining process, and three wastes processing technology, and adaptive ability of poor crude process. Based on effective process innovation and product innovation, the petrochemical enterprises reduce the consumption of energy resources and materials in manufacturing process, adjust the structure of refined products, produce clean fuels with high standards and realize a minimum of unit-product carbon emission.

4.2 Integrating innovative process and innovation organizations

At present, the process of technology innovation shows with characteristics of integration, flexibility, network and parallel information processing, which requires transform former linear mode into parallel mode. Such a change emphasizes on communication and cooperation among the different departments of research, design, production, suppliers and customers. With regard to disruptive innovation, significant breakthrough innovation as well as industrial key generic technology oriented by low carbon, it's not far from enough to only depend on inner R&D of enterprise or cooperation between the upstream and downstream firms. In addition to the participation of enterprises, universities, research institutions, some other actors like government departments, financial organizations and sci-tech intermediaries, play a synergistic role through resource sharing and complementary advantages in the chain of technology innovation. As integrated innovation has characteristics of actor's diversification and networking, accompanying with the integration of knowledge and talent, the industry can have powerful technology accumulation and supporting condition in a relatively short period, reduce the barrier and cost of innovation, improve the efficiency of innovation and shorten the cycle from R&D to industrialization. In fact, integrated innovation has transcended pure technology innovation, and paid more attention on the integration of technology, strategy, organizational structure, and culture, which seeks to integrate knowledge and capability of enterprises for synergy innovation.

4.3 Establishing strategic alliance of low carbon technology innovation

Due to the development of low-carbon economy and the roles of petrochemical industry in CO₂ emission reduction, it is imperative to establish strategic alliances for low carbon technology innovation, in which petrochemical enterprises act as the main body of technology innovation and governments act as the initiator and main enabler of strategic alliance. Governments select partners including industrial leaders, important enterprises in the industrial chains, universities and research institutes with core technology, to set up the strategic alliance.

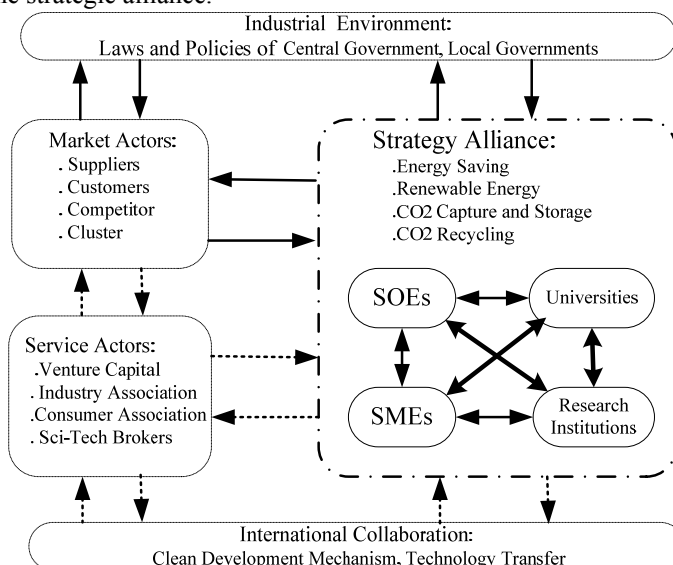

Figure 2 Strategic Alliance for Low Carbon Technology of Petrochemical Industry

The alliance seeks to explore a new cooperative mechanism based on low carbon development

strategy, focus on fundamental, strategic and prospective research and solve key and generic technologies concerning industrial sustainable development. Because of historical reasons, Chinese petrochemical industry shows multi-market patterns and takes strict measures to protect core technology from each other, so the government should act as the coordinator and guider to promote technology transfer. The important roles of strategy alliance are to enhance the competitiveness and key technology in the international market based on mastering accurately the trends of industry. Represented by the second-generation bio-fuels, a set of technologies in growing stage are appropriate for alliances to focus on, however, some technologies in the introductory stage, such as CCS, carbon chemistry engineering, could be foresight studies as strategic technology reserves for the future. Since the petrochemical industry is comparatively mature, so it is necessary to pay high attention to new energy field in case the disruptive innovation brings destructive effect on the present petrochemical industry.

5 Conclusions

Chinese government put forward innovation-driven strategy and highlights the path of independent innovation with Chinese characteristics, which aims at synergy innovation among original innovation, integrated innovation as well as import, digestion, absorption and re-innovation. To achieve the goals of low-carbon development, Chinese petrochemical industry must play coordinated roles of technology and system innovation to ensure the safety of energy, deal with climate change and promote economic development, and meanwhile, promote the whole social economy to transform into a high efficiency, low-energy and low-carbon mode. Some preferential policies to major technology reconstruction, such as energy conservation, CO₂ emission reduction, tax incentives and loan policies to CO₂ resource utilization, should greatly promote low carbon technology innovation. Meanwhile, the government funding should support forward-looking research with the help of universities and research institutes. By the ways of adjusting and upgrading industrial structure, business structure and product mix, it is expected to promote industrial concentration and resource utilization which is helpful to reduce CO₂ emission and improve international competition.

It is worth mentioning that Clean Development Mechanism (CDM), an innovative international cooperative mechanism for climate change between developed and developing countries, is proved as a win-win mechanism that can reduce the cost of emission reduction for developed countries and obtains advanced technology and additional funds for developing countries by launching project cooperation [10]. Chinese petrochemical industry should pay more attention to and make use of CDM so as to obtain advanced technologies of energy-saving, cogeneration and new energy through close cooperation with foreign oil corporations.

Functions of Design Management on Upgrading Industrial Design in China

Zhou Ziqin

College of Art and Media, China University of Geosciences, Wuhan, P. R. China, 430070

(E-mail: 449834566@qq.com)

Abstract: Design management, as one of the functional strategies, must serve the over-all strategy of the entire enterprise and it's a relatively new research field. Since late 1990s, researchers have laid great emphasis on design management. With large quantity of effective experiences gained in operating process, some theoretical systems have been initially formed. As a cross product of two disciplines, design management possesses extremely important practical significance in enterprise operating strategy, particularly in art industry. Industrial design in China starts relatively late, and there's an obvious gap between China and industrial design powerhouses, especially in innovation. This paper analyzes the current situation of China's industrial design, and mainly discusses the significance of design management in upgrading China's industrial design.

Key words: Design Management; China's Industrial Design; Design Levels; Cultural Creation

1 Introduction

As to the definition of design management, there are different understandings of design management from different perspectives. To sum up, a general understanding of design management can be summarized as follows: design management is a multidimensional management program that leads the overall cultural image of an enterprise. Design management is the realization of development strategies and implementation plans, and is a high unified carrier of the visual image and technology. It attaches development and design as the leader, properly adjusts the activities and organizations of the enterprises to create a more concrete manifestation belonging to its own, so as to gradually form the image of the enterprise technology and culture. Therefore, the design management is: "to carry out systematic and organized research and development management activities according to the needs of users. It is the management of a series of design strategies and activities that are carried out to effectively activate the designers' creative thinking, to converge the market's and the consumer's ideas in the new products, to affect and change people's lives in a more rational and more scientific way, and to maximize the profits of the enterprise" Design management is a method that makes design less complex. As one of the functional strategies, it must serve the over-all strategy of the entire enterprise. In China, the industrial design industry is relatively better developed in Beijing, Yangtze River Delta region with Shanghai being its representative and the Pearl River Delta region with Shenzhen being its representative. In recent years, the Chinese mainland enterprises have invested millions of dollars in product design, however, due to the economic, cultural, scientific and technological factors and the quality of employees, many enterprises lack scientific ideas of design management and they also haven't found any suitable and effective ways to improve enterprise structure, the allocation of the enterprise resources, the comprehensive strength and efficiency of the enterprise by utilizing design management.

This paper analyzes the major problems facing the industrial design in China and also puts forward a design idea that combines design management with industrial design, spontaneous design with rational design ideas, which is a fairly effective way for industrial design in China to achieve rapid advancement.

2 Analyses on Current Situation of Chinese Industrial Design

At present, the industrial design in our country generally, boasts a good momentum of development; some large enterprises have attached importance to industrial design and have made certain achievements. However, there still exist many problems in the field of product design, which mainly lie in the lack of design research yet fail to receive enough attention from most enterprises. At the same time, the enterprises' and consumers' understanding of the industrial design merely reside in beautifying the appearance. This kind of wrong understanding leads to the unessential position of industrial design in product development & design, and the lack of effective promotion and application of the existing results. Due to the small investment, the lack of design and response ability in developing new products and upgrading the old ones, and the training of design personnel couldn't catch up with development, the Chinese enterprises haven't digested the introduced advanced technology and products in the point

of design. Many domestic enterprises do not realize the importance of innovative design of products, and especially the industrial design is poorly understood by mainland enterprises, at the same time, they also do not have the enough understanding in the product brand; therefore they suffer a great loss. In the international market, huge profits belong to the independent brand enterprise. As the labor-intensive manufacturing, processing sectors, the technical content is low; the profit space is small, and easy to be replaced by peers, so they are in the bottom of the value chain curve. The value chain curve, namely the smile curve, is shown in Figure 1:

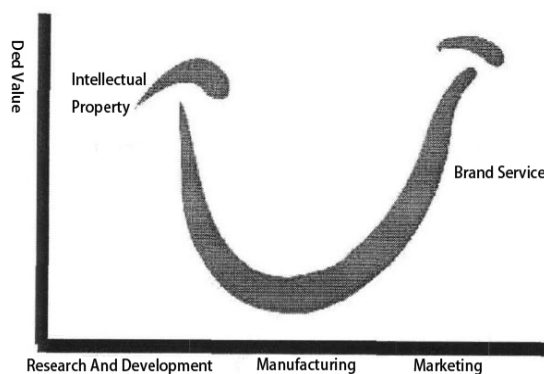

Figure 1

Simple and vulgar designs label products made in China as being poor in quality and low in price; too much imitation and introduction, and the determination to save trouble make Chinese enterprises lose the patience to cultivate the ability in product design innovation, therefore they cannot form their own brand awareness.

The industrial design of our country is still in the stage of a production-oriented industrial design; imitation and plagiarism are also still common problems. Theoretically, market research is the premise of industrial design; it can be obtained by qualitative analysis and quantitative analysis. But in actual operation, it's not easy to grasp the consumers' real expectations. Especially after joining the World Trade Organization, our enterprises have to face such problem as the patent infringement issues brought by plagiarism. In addition, our enterprises know little about the basic knowledge of intellectual property protection; and they don't pay attention to claims for the intellectual property rights, resulting in a large number of losses of intellectual property rights.

3 Functions of Design Management in Industrial Design

3.1 Key points in design management

In today's information and agile era, design management is more challenging and risky than ever before. It is a kind of thinking skill. The existing strategy center has been extended to a commercial tactical level beyond the boundaries of digital and technology. Under today's circumstance of products and technology, the corporate image and operational efficiency are quite significant to the enterprises' survival. Design management can maintain a continuous development of the enterprises and effectively improve the results of commercial activities. A company with a very popular image will win the trust of its supporters and groups. Thus you can see the key points of design management are: ① Design management is a normal, basic and specific assessment and application aiming at the institutions and business operations of business communities at all levels of the society; ② The aim of design management is to create a clear, unique and cohesive community image that can intensively display a company that is with continuous development prospects and enormous potential to create wealth, and is continuously advancing and developing; ③ To establish a community image and consolidate this image primarily based on its products, information and the attractiveness of its environmental media, and the image should especially be associated with its product design; ④ Make a rational use of resources in all aspects of the community, fully mobilize all the favorable factors of external organizations to accomplish any task of the company, and implement these intuitive actions to the end; ⑤ A logical, creative and flexible management plan has led to the continuous development of the design, the development of creative products, and economic feasibility; ⑥ The creation of a community's image is based on its culture, and it should subject to management and evaluation of the wide public; ⑦ Fully coordinate communication and interaction within the company as well as between companies and social

groups, to help companies to deal with the ever-changing realities in the market, and encourage companies to seek future success; ⑧ Design management is a new thing. It is constantly updating its tasks and requirements, it is investing in intangible assets that are valuable, meaningful, immeasurable for any company; ⑨ Design management advocates for the integration of design and management, and the expansion of the design to the whole community; ⑩ In the current high-tech conditions, the core of design management is to establish a virtual organization.

3.2 Functions of design management in industrial design

In terms of the current situation of Chinese industrial design, design management could play an important and practical role in design strategy, design process and design enforcement.

The purpose of design management is to identify and figure out which method could be adapted by design to contribute to the industry. Therefore, grasping the design opportunity is the first step to achieve that goal. As part of the product, the design is not purely a form of art, the fundamental goal of design is to be successful in the market and win profit for the enterprises. In recent years, there's a growing demand for clearly defined design hierarchy and using it as a prerequisite for industrial design.

Products are unlikely to meet the needs of all levels, nor for all people. The main task of design managers is to help enterprises to seek the balance between the design quality and cost. Different levels of consumers and enterprises pursue different goals. In the era of material scarcity, with lower living standards, consumers conducted sensible consumption behavior, and they preferred to cheap and durable products. In most areas of our country, consumers judge products only by considering whether they are "good" or "bad". Products which only meet the basic using value and also have low prices are easier for consumers to accept. Such a market is what we called the low-end market, by sacrificing some product elements to exchange low cost, thus providing a lower price. With the development of economy and the rising of living standards, the performance-to-price ratio becomes more complex and consumers have more requirements in products. Then consumers hope products can reflect their personality, social status and aesthetic taste, to meet their own psychological "pleasure".

Design does not exist independently, in terms of design strategy management, using the clearly defined design hierarchy will be conducive for industrial designers to improve the design aim and sense of hierarchy. In addition, with clearer target, it also will help to break through the bottleneck of industrial design innovation.

Design is a strict, cycle process that is full of questioning and innovation. The design process consists of a series of methods, with these methods we can solve the design project and design issues. The design process, derived from a series of trials and tests is made to solve the problems and it's applied by the designer or design team to customers' projects, thus could be constantly revised.

Cultural creation has a great importance on industrial design. It is self-evident. Looking for creation from the vast history of deep inspiration and the traditional culture is the main way for Chinese industrial design to embark on a road of cultural creation.

The idea and purpose are under the influence of national culture, and are also connected with industrial development level of each country and people's consumption consciousness. In order to design the product that has a certain international competitiveness and will be popular in the market, conducting the national culture innovation is an excellent method. With the deepening of economic globalization and integration, there's a growing awareness of people that a design with an integration of national culture is more competitive the global market. "Regression" and the integration of national culture and characteristics of times have become a trend in Chinese industrial design. The traditional elements have been blended into more and more product designs, such as the "Chinese knot", "Red China" and the auspicious clouds pattern, these symbols have strong ethnic characteristics and have been widely used in design industry, all of these unique Chinese styles have found favor with the designing world. This kind of design with strong ethnic style and cultural features is warmly welcomed in the market.

During design process, the designers often lay great emphasis on cultural creation; however, they always lack perfect management in design process and implementation. Design process and management implementation could effectively promote the design elements essential to be reflected in the final design work in the design, so as to ensure the quality of work.

3.3 Product design management within network technology

Driven by high and new technology, the application of network technology in design management is more outstanding. Under unified control of the product design and management center, various factors in CAID are interrelated through the network to form a complex and orderly organic entirety, which is a typical pattern in concurrent design. It is under such a condition of group network that the independence

of each department in the traditional design was able to be broken completely, and the whole design and manufacturing system can stay in an orderly condition with unified control and collaborative work. Only through collaborated work of every department, can the enterprises adapt to customers' changing demands and respond quickly to the market so that to develop the marketable products as soon as possible.

Under such background, the "virtual product development" (VPD) came into being. VPD is based on the integrated products and data management. The benefit of this integration is that all staff in the process of product development can quickly re-use and restore the required information. The aim of VPD is to replace as much physical prototype testing as possible, and to reduce the wasted time of using physical prototype testing. The more the engineers get in computers, the better, and they can design more products with a faster speed and higher quality. The essential process of product design and development is to monitor and predict the functionality, performance, workability and other possible problems of products through computer simulation models, in order to improve product forecasting and decision-making level, and make the product development work out of the narrow world relying on experience into a new stage of all-round forecasting. And through the world network environment - Internet, various manufacturers can quickly carry out technical cooperation, share each other's core resources, and quickly design and produce products with high quality and low cost to meet the market's demand, and to turn agile manufacturing into reality.

4 Conclusion

In the present competition situation, design management is not only a kind of integration and promotion of design resources, more importantly, as a method of management, it should raise decision-making level, and it has very important significance in the art industry. In industrial design, through rigorous and normative management, design management can enhance the designer's pertinence and sense of hierarchy in the design process, promoting the reflection of essential elements in the design works. Therefore, the rational use of design management has the extremely important practical significance in upgrading the Chinese industrial design.

A Study on the Growth of Emerging Economies and Their National Income Distribution

Chirinos Adriana

Wuhan University of Technology, School of Management, Wuhan, P.R. China, 430070

(E-mail: adrianachirinos20@hotmail.com)

Abstract: The last decade has presented a new global economic scenario lead by emerging markets. BRICS countries (comprised by Brazil, Russia, India, China and South Africa) have been at the forefront in this phenomenon. During these years, the real Gross Domestic Product (GDP) growth of the world (annual percent change - A% c) averages 3,83. It is worth mentioning that the above referenced countries reached 6,01 (157,02% more); and Advanced Economies - not yet recovered since the last financial crisis - reached 1,6 (47,78%). Meanwhile, different measuring models have found that in the world, just the top 20% of the population controls over 70% of the global revenue. These economies have been growing as well. The importance of this investigation is answering the questions: Are they reversing this lack of equality trend? And, Would be relevant to add equity in the development agenda?. This paper offers an analysis of these points and studies them as a strategy for sustainability and continuous growth.

Key words: BRICS countries growth; National income distribution; Equity in the development agenda.

1 Introduction

BRICS Countries are leading the growth of the economy in the world, and have done so for over 10 years. The International Monetary Fund (IMF) projected that from 2013 to 2017 it will maintain its growth at least 26% above World Growth GDP. Note: GDP, will be the measure utilized in this paper when referring to growing economies. This information comes from the IMF data base and calculations made by the author.

Income distribution refers to how a nation’s total GDP is distributed among its population (Sullivan and Sheffrin, 2003). This distribution is typically unequal, and becomes an issue which has been avoided for many years. In 2004, this trend changed when the International Labor Organization (ILO) published: “A Fair Globalization.” After this occurred, other major development-related institutions followed suit and began posting about inequality as well. Currently, there is a unanimous concern in international institutions about that issue and it has become clear that the issue of inequality must be incorporated in discussions about development.

This paper analyzes: (i) Distribution of income or consumption per country, (ii) Gini Index and, (iii) Understanding the background of these countries, this research also incorporates information regarding poverty per country. All the data comes from the World Bank and the calculations made by the author. This paper also discusses the negative consequences of rising inequality and defines the importance of adding equity in the development agenda, as a strategy for sustainability and long-term growth.

2 Growth in BRICS Countries

Figure 1 Real GDP Growth (Annual percent change) 1991 to 2017

The Figure 1, shows the argument that as introduces the research and salient facts may be

mentioned; (i) 2003 and 2004, emerging economies (BRICS) began a significant consolidated period of growth (and were already doing so), during these two years, their GDP increased from 5,64 to 7,04 (ii) 2008 (September), the outbreak of the global crisis obviously affects everyone. BRICS fell in 2009 to 1,1 (fall but remain in positive), the world economy: -0,6 and Developing Economies: -3,5 (iii) After the global crisis, very slow recovery in developed economies and promising trend showing the BRICS economies.

This graph (figure 1), also evidenced the situation and positioning: BRICS, Advanced Economies and World, from 1991 (since all these countries have data) to 2017, from 2013 to 2017 are projections.

Considering information about the last 10 years (2003- 2012), the position and growth average for each BRICS country (including the world as well) is: **China: 10,45%, India: 7,76%, Russia: 4,73%, world: 3,83%, Brazil: 3,67% and South Africa: 3,46%**. All of them have correlated well with the “world” result, except China, with a strong first place position, followed by India (See Figure 2).

Figure 2 Real GDP Growth BRICS Countries (Annual Percent Change) 2003- 2012

However, fast growth in economies with a background of instability might not be sustainable. From a statistical point of view, when deciding whether measurements agree with a theoretical prediction, the standard deviation of those measurements is of crucial importance: if the mean of the measurements is too far away from the prediction, then the theory being tested probably needs to be revised. (DeVore, 2005).

The following comparison was also done for these economies. (See Figure 3):

Figure 3 Market Instability (Mean Vs. Standard Deviation) 2003- 2012

From these results it can be determined which country seems to have higher or lower levels of uncertainty. From higher to lower, the order is the following China and India (far away from the rest), then, South Africa, Brazil, and Russia. Almost the same positioning reached in its growth.

The new global economic scenario has changed phenomenally in the last decades. Securing a sustained growth in the coming years will be crucial in reducing the level of uncertainty for these countries; therefore, it becomes necessary to implement adequate strategies.

3 National Income Distribution

How is income distributed worldwide? (Ortiz and Cummins, 2011). We inhabit a planet in which the top 20% of the population controls over 70% of global revenue. What about BRICS countries?

The following is an analysis for each country: (i) distribution of income, reflected in the percentage of shares of income or consumption accruing to portions of the population and ranked by levels (deciles in this paper): highest (more income); lowest (less or no income). (ii) The Gini Index-Lorenz Curve, which represents the distribution of income within a community, plotted with a Lorenz curve, where “0” means perfect equality, and “100” implies perfect inequality (World Bank, 2013). (iii) Poverty; considering the percentage of the population living on less than \$2,00 (which covers the \$1,25 a day at 2005 international prices).

The figure 4 make more completed the analysis, showing graphically the main variables per country during: 1994 -2002, 2003 – 2012 (last decade), and the average. Also, as a visual reminder contrasted with its GDP growth average analyzed before (2003-2012). The data includes all available years, from 1994 to the last available year (each country has different years of information availability).

Figure 4 Comparison Between BRICS: Growth / Income Distribution / Gini / Poverty (1994- 2012 or Years Available)

3.1 Brazil: The only South American member of the Group, with a population of 196,7 million in 2011 (last year published). There has been some improvement in the incomes distribution, as well, growth of the economy. Considering data from 1990 to 2009; the 20% highest of the population (people with more incomes) controlled: Averages 62,24% of incomes while 20% lowest just 2,38%. The highest deciles (10-20%) have been going down and the lowest (20%) have been going slightly up. More people are joining the middle class. Concerning poverty, it has consistently improved, however moderately; nevertheless, by 2009 they have 10.8% of its population living in poverty. That means a total of 21,2 millions of people. The Gini Index has descended to 6,35 in the same period of time. This country shows the best results in terms of proportion of improvement.

3.2 China: The Asian giant has recently given so much to talk about in terms of growth, with a

population of 1.344,1 million. Contrary to economic growth, not so well results exposed, with data from 1990 – 2005 (last available), the 20% Highest of the population control: Avg. 45%, while 20% lowest just 6,58%. Overall, it looks like the lowest 10%-20% of the population is poorer, and the highest 10%-20% just descended somewhat. The Gini index jumped by 10,5 in the same period. Regarding poverty (one additional year of data - 2009), it is clear that there has been a descent (2,6%), in this country it is equal to aprox. 34,8 millions of people. However, by the last year available it shows 27,2% of its population living in poverty. That means 365,6 millions of people (almost two Brazil).

3.3 India: Another Asian populated giant. It shows a huge growth and a population of 1.241,5 millions of people. Concerning income distribution: data of: 1994 and 2005 (years available); the proportion is: 20% Highest: Avg. 41,25% and 20% lowest: just 8,8%. There are no significant changes during the time, except that the highest 10-20% of the population (wealthy people) has been receiving more income. The Gini index jumped to 2,56. Poverty levels have improved (based on one more year of data -2010). However, by the year 2010 it had an amazing 68,72% of its population living in poverty. That means 853,2 millions of people (more than China, which has more population).

3.4 Russia: The largest country in the world, with a population of 143 million. Its income distribution, from 1993 to 2009: The highest 20% control Avg. 47,07% of incomes, while 20% lowest 5,96%. In this economy, each decile is closer to each other. The Gini Index descended: 8,27 points. Poverty has decreased. By 2009 the result for “\$1,25 a day” is: 0% and “\$2 a day” is: 0,1%. That means 142,9 thousand people. They show the best result in terms of “absolute numbers” in the BRICS countries.

3.5 South Africa: The newest member of the BRICS group and a country representative of Africa. It had a population of 50,6 million in 2011. Considering data from 1993 to 2009 (last year available), the gap between the highest levels (10-20%) and the rest of the population (48,67 points) is disturbing. Here the proportion is: 20% Highest: 65,85% and 20% Lowest: 2,95%. In terms of poverty, it can be said that it has decreased but not significantly. During sixteen (16) years: 9,7 points. That means that by 2009, approximately 15,8 million of its people (31,3%) still live in poverty.

(Ortiz and Cummins, 2011), while it is true that there is some evidence of progress, it is too slow.

We estimate that it would take more than 800 years for the bottom billion to achieve ten percent of global income. Every economy must double its efforts in order to build an integral development agenda in order to improve in the area of social politics, environment, and climate change.

4 Importance of Adding Equity in the Development Agenda

Inequality also matters to economic growth. In order to ensure that sustainable growth continues, and also, in order to allow other developing countries to join better economy situations, a similar employment-intensive push in the agenda becomes necessary, as well as an international setting favorable to such agenda. Understanding the negative consequences of rising inequality becomes crucial to the progress of the economy of the nations.

4.1 Lack of equality inhibits growth, In the 1950s, Simon Kuznets argued that income inequality is necessary for the growth of the economy. Supporters of this position advise investing in growth as a first priority because they believe that the benefits will “trickle down” to the poor. However, (Bourguignon, 2004), (Birdsall, 2005), among others, suggests the contrary. (Ortiz and Cummins, 2011), using 131 as sample of countries from 1990 to 2008, it was found that countries with increased levels of inequality experienced slower annual growth per capita GDP ($\rho = -0.20$). Moreover, the strong negative correlation between high inequality and high growth remains virtually unchanged when restricting the sample to developing countries only. (94 countries) ($\rho = -0.19$)

4.2 Inequality generates social and health problems, (Wilkinson and Pickett, 2010) examine the relationship between income inequality and eleven unique health and social problems. They developed the International Index of Health and Social Problems (IHSP). The composite index covers 23 countries and includes the following indicators: number of homicides, imprisonment, infant mortality, life expectancy, math and literacy scores, mental illness, obesity, social mobility, births by teenagers, and trust. They find a strong relationship between high levels of inequality and greater health and social problems ($\rho = 0.54$).

4.3 Inequality produces political instability, the sources of political conflict vary from country to country, some causes included: class conflicts, perception of inequality between ethnic, religious or others. (Alesina and Perotti, 1996), among others, argue that inequality can lead to less political stability, and this in turn can lead to sub-optimal investment levels. They present an extensive battery of robustness tests on a cross-section of 70 countries, for the period 1960 – 1985, a two- equation system in

which the endogenous variables are: investment in physical capital and a measure of political instability. Their results in sample of 70 countries are quite solid.

Adding equity to the Development Agenda is beneficial and imperative right now, not only because it is correct seeking balance or because is a worthy cause, but also because equity is a guarantee and an innovative strategy for growth and sustainability.

5 Conclusion

It is clear that the BRICS countries are at the forefront of the GDP growth worldwide. As a group, considering the last 10 years, the GDP average growth of the BRICS countries is 6,0% and the world's is 3,83%. Meanwhile, for all of them, the highest concentration of income is controlled by a few people. The highest 20% of the population controlled 52,3% of the income and the lowest 20% controlled just 5,3%. The Gini Index Average is 46, and 41,9% of the population is living in poverty, that is means: 1.255,9 millions of people (approximately 18% of the population of the world).

Finding the right balance between equity and growth is required. Mainstreaming equity in the development agenda, striving to achieve the equity/growth balance requires a major overhaul of current decision making. Economy-related choices at both international and national levels have often been made without proper consideration for their distributional impact. If there is a negative social impact, it could be mitigated, but we must be aware that equality and social progress cannot be achieved solely by following this approach.

The Implantation of public policies that focused on generating employment and household income, ensuring access to land and assets, as well as infrastructure and services, and enhancing human capital and labour productivity are need as a guarantee and an innovative strategy for growth and sustainability.

Countermeasures of the Industrial Energy Consumption Based on the Industrial Economic Increase in Wuhan of China*

Li Zhihong

Business School, Jiangnan University, Wuhan, P.R.China, 430056
(E-mail: linanwudingbang@163.com)

Abstract: During the 12th Five Year Plan, energy saving plays an important role in the sustainable development of the industrial economy in Wuhan. The paper further explores the correlation between the industrial energy consumption and the economic growth in Wuhan by analyzing in detail the actual situation and features of the industrial energy consumption of Wuhan. Then, the paper puts forward some suggestions on the energy consumption in promoting the sustainable development of the industry in Wuhan. Finally, the paper draws a conclusion that the renewable energy development and the energy saving decide whether the industrial economy increase can be sustainable or not.

Key words: Industry in Wuhan; Energy consumption; Suggestions; Correlation analysis

1 Introduction

Since the 11th Five Year Plan, the industry in Wuhan has grown rapidly. With the industrial transformation and upgrading in Wuhan, energy has become the bottleneck to curb the development of the industrial economy and the pressure of energy-saving and industrial emission-reduction been intensified. For the sake of further accelerating the development of the industrial economy in Wuhan in the new era, it's a worthy issue to deeply explore the industrial energy consumption.

2 Actual Situation and Features of the Industrial Energy Consumption in Wuhan

2.1 Industrial energy consumption rises year by year in total, but drops in unit output value

According to the statistic data in Table 1, the total energy consumption in Wuhan from 2000 to 2011 is respectively 2485.33, 2265.24, 2356.15, 2615.67, 3274.48, 3255.39, 3828.17, 3884.03, 3914.27, 3741.91, 4071.71 and 4396.63 tons of standard coal. Except 2009, the total energy consumption gradually rises in the other years. The energy consumption per ten-thousand-Yuan industrial output value drops from 2000 to 2011 except 2002 and 2004.

Table 1 Over-scale Industrial Energy Consumption in Wuhan from 2000 to 2011

Year	Over-scale industrial energy consumption (converted to standard coal) (ten-thousand tons)	Energy consumption per ten-thousand-yuan industrial output(converting to standard coal)
2000	2485.33	1.43
2001	2265.24	1.15
2002	2356.15	1.35
2003	2615.67	0.82
2004	3274.48	0.94
2005	3255.39	0.81
2006	3828.17	0.79
2007	3884.03	0.63
2008	3914.27	0.45
2009	3741.91	0.34
2010	4071.71	0.29
2011	4396.63	0.27

Note: Data in 2010 and 2011 from Wuhan Statistic Yearly Book 2012

* The paper is supported both by the MOE Project of Key Research Institute of Humanities and Social Science in University Wuhan and by the Research Centre on the Development of the Manufacturing Industry of the Wuhan City Circle, China.

Other data from Wuhan Statistic Yearly Book 2010 and in 2004, data are from the economic census and the electric converting coefficient in 2005 was changed into 1.229 from 4.04.

2.2 Industrial energy consumption in unit output value added in each district of Wuhan drops, but that of Qingshan and Xinzhou districts remains in a rather high level

In 2011, except Qingshan and Xinzhou districts, the industrial energy consumption in unit output value added in each district of Wuhan was stabilized below 1 ton standard coal per ten thousand yuan, but that of these two respectively got to 3.76 and 3.34 ton standard coal per ten thousand yuan, which far surpassed that of the others. The drop degree of the industrial energy consumption in unit output value added in Xinzhou was -8.92% while that in Qingshan -5.11%(see Table 2, Figure 1).

Table 2 Comparison of the Energy Consumption in all the Districts of Wuhan in 2011

Districts	Industrial energy consumption in unit output value added (ton standard coal per ten thousand yuan)	Fluctuation of the industrial energy consumption in unit output value added ($\pm\%$)
Jiang'an	0.39	-12.94
Jianghan	0.12	-4.45
Qiaokou	0.54	-19.02
Hanyang	0.04	-11.69
Wuchang	0.44	11.67
Qingshan	3.76	-5.11
Hongshan	0.15	-13.45
Dongxihu	0.24	-21.08
Hannan	0.89	20.23
Caidian	0.15	-6.67
Jiangxia	0.32	-17.98
Huangpi	0.51	-15.87
Xinzhou	3.34	-8.92
Donghu Hi-tech. Development District	0.12	-11.54
Wuhan Economy-Technology Development District	0.15	-12.35

2.3 Electricity consumption of above-designated-size industry evidently drops and is gradually stabilized during the 11th Five Year Plan, compared with that in the 10th Five Year Plan, but a little rises in the 12th Five Year Plan

In the 11th Five-Year-Plan period, the electricity consumption of the above-designated-size industry has dropped much in comparison with that in the 10th Five-Year-Plan period (see Table 3). The drops occurred respectively from 403.96, 442.30, 325.54, 395.33 and 710.32 standard coal/ten-thousand tons converted in 2000, 2001, 2002, 2003 and 2004 to 223.26, 178.24, 215.37, 221.32 and 229.67 standard coal/ten-thousand tons converted in 2005, 2006, 2007, 2008 and 2009. However, at the beginning of the 12th Five-Year-Plan, the electricity consumption is up a little, compared with that of the 11th Five-Year-Plan.

In the 11th Five-Year-Plan period, the coal consumption of the above-designated-size industry has risen in comparison with that in the 10th Five-Year-Plan period (see Figure 1). The ups occurred respectively from 926.39, 863.67, 950.27, 1084.49 and 1435.12 standard coal/ten-thousand tons converted in 2000, 2001, 2002, 2003 and 2004 to 1742.06, 1891.64, 1863.85, 1793.92 and 1672.25 standard coal/ten-thousand tons converted in 2005, 2006, 2007, 2008 and 2009. However, at the beginning of the 12th Five-Year-Plan, the coal consumption is up a little, compared with that at the end of the 11th Five-Year-Plan.

Table 3 Comparison Between the Electricity Consumption and the Coal Consumption of the Above-Designated-Size Industry

Year	Coal (converted to standard coal/ten-thousand tons)	Electricity (converted to standard coal/ten-thousand tons)
2000	926.39	403.96
2001	863.67	442.30
2002	950.27	325.54
2003	1084.49	395.33
2004	1435.12	710.32
2005	1742.06	223.26
2006	1891.64	178.24
2007	1863.85	215.37
2008	1793.92	221.32
2009	1672.25	229.67
2010	1768.01	259.98
2011	1027.95	296.52

Figure 1 Comparison Between the Electricity Consumption and the Coal Consumption of the Above-Designated-Size Industry

3 Analysis of the Industrial Energy Consumption in Wuhan

3.1 Positive correlation does not necessarily exist between the industrial economic increase and the industrial energy consumption

Seen from Figure 2, before 2006, the increase rate of the energy consumption of above-designated-size industry surpassed that of the total industrial output in Wuhan. From 2007 to 2011, the increase rate of the total industrial output surpassed that of the energy consumption of above-designated-size industry in Wuhan. Especially since recent three years, the increase rate of the total industrial output has been far beyond that of the energy consumption of above-designated-size industry in Wuhan (see Table 4). This phenomenon shows us that although the increase of the industrial economy needs the support of the energy, the energy consumption volume is able to be controlled and the correlation between the industrial economic increase and the industrial energy consumption is not always positive.

Table 4 Energy Consumption and Total Industrial Output in Wuhan

Year	Over-scale industrial energy consumption (converted to standard coal) (ten-thousand tons)	Total industrial output in Wuhan (100 million yuan)
2000	2485.33	1422.37
2001	2265.24	1611.76
2002	2356.15	1769.92
2003	2615.67	1994.49
2004	3274.48	2402.34
2005	3255.39	2674.41
2006	3828.17	3162.06
2007	3884.03	4010.30
2008	3914.27	6251.79
2009	3741.91	6317.94
2010	4071.71	7004.96
2011	4396.63	8461.21

**Figure 2 Comparison Between the Energy Consumption and the Total Industrial Output of the Above-Designated-Size Industry in Wuhan**

3.2 Too much reliance on the traditional energy by the industrial economic increase in Wuhan does no good to the expansion of new varieties of energy consumption

The energy consumption in Wuhan still mainly relies on coal, electricity, oil and gas. In 2011, of the energy consumption, coal occupied 1027.95 standard coal/ten-thousand tons converted with a proportion of 23.38%, coke was 668.84 standard coal/ten-thousand tons converted with a proportion of 15.21%, crude oil accounted for 720.11 standard coal/ten-thousand tons converted with a proportion of 16.38%, electricity was 296.52 standard coal/ten-thousand tons converted with a proportion of 6.74% and gas occupied 197.32 standard coal/ten-thousand tons converted with a proportion of 4.85%. The sum of their energy consumption accounted for 61.71% of the total, which says that too much traditional energy consumption existed. With the further economic development and without the substitute available, the reliance on the traditional energy will be deepened and this will do no good to developing the new energy and expanding its new varieties.

3.3 The energy consumption of all the districts in Wuhan goes downward, but a few of them still leave much room to drop

In 2011, the industrial energy consumption in unit output value added of Qingshan and Xinzhou districts was respectively 3.76 and 3.34 ton standard coal per ten thousand yuan. The drop degree of the industrial energy consumption in unit output value added in Xinzhou was -8.92% while that in Qingshan -5.11%. All these tell us that much room in these two districts is to be narrowed.

4 Countermeasures of the Industrial Energy Consumption in Wuhan

4.1 Saving energy by relying on the progress of science and technology

Energy consumption can be reduced by increasing the scientific and technological content and improving crafts. Take it for example that Wuhan Steel and Iron Group has greatly raised its level in using the crude fuel for the blast furnace and reduced the coke ratio in iron-making by making use of energy-saving technology like sintering waste heat power generation and the thick layer, etc.

Energy can be utilized comprehensively by technological innovation. Wuhan Steel and Iron Group has realized the optimization of the fuel structure and the cascade utilization of energy and made the energy consumption per ton reach the advanced level at home by recycling the waste gas and heat in the blast furnace, ovens and converters and so on.

4.2 Saving energy by relying on optimizing the industrial structure

The actual situation of the layout of the industry in Wuhan is that the secondary industry occupies a very important place in the industrial structure. But the secondary industry consumes too much energy, which makes the energy supply in great pressure. The optimization of the industrial structure can relieve the tension of the energy consumption. The main countermeasures are to develop in priority the industries which can play an important leading role in the economic increase and those with a low-carbon economy such as high equipment industry, electronic information industry and bio-medicine industry, etc. Also, these enterprises with overcapacity, high energy consumption and high emission should be eliminated continuously. In the 11th Five-Year-Plan period, 65 enterprises which were diagnosed to be supervised in stress as high energy consumption ones had been reduced to 53 by shutting off, stopping, merger or transfer, etc. These measures have played an active role in raising the efficiency of the energy utilization and in the energy saving.

4.3 Making a full use of the recyclable energy by innovating and adopting the hi-tech

Seeing that the industrial economy in Wuhan has been developing fast and that the energy varieties available are limited, it is necessary to further strengthen the exploitation of the new energy so as to realize comprehensively the diversification of the energy consumption. The details are presented as follows:

1) Fully utilize the solar energy and the wind energy. In 2007, 6 demonstration bases for the solar energy were set up and they can make the solar energy technology serve the road lamp power. Take it for example that the road lamps installed in such streets as Hankou Yanjiang, Hankou Jiangtan in Wuhan can generate electricity both by using the solar and the wind energy and realize the zero expenditure and the zero emission.

2) Fully utilize the bio-energy. For example, the gasohol developed by Wuhan Dibo Petrochemical Company is a kind of fuel of environmental protection used for automobiles. It is a mixed energy from the fuel ethanol that is made from grain and various plant fiber and the regular gasoline in certain proportion. It can effectively improve the performance and quality of oil, reduce the emission of the pollutants like carbon monoxide and hydrocarbons.

3) Generate electricity by recycling wastes. According to some statistics, the daily production of the wastes in Wuhan is 600 tons and the yearly one nearly gets to 220 thousand tons and increases per year by 8%. The Environmental Science Institutes in Wuhan says that the content of the organics in the wastes in 13 years has increased by 3.89 times, which makes the wastes in Wuhan more fit for incineration. In recent years, Wuhan has been engaged in developing the projects of generating power by recycling the wastes and several power stations of incinerating the wastes like Jiangxia Fenghuangshan, Caidian Qianzishan and Guodingshan, etc have been set up. The Guodingshan Power Station has a total capacity of 40 thousand kilowatt and can recycle 1500 tons of the wastes every day with a yearly electricity generation of 220 million degree that is equivalent to the daily electricity used by Hubei Province and that can reduce over 80% of the wastes.

5 Conclusions

From the above research, we may draw the following conclusion: the fast development of the industrial economy can't be separated from the support of the energy. Due to the limitation of the traditional energy, we must save the energy and develop the renewable one to substitute the traditional energy by innovating science and technology, optimizing the industrial structure, fully utilizing the solar energy, the wind energy, the bio-energy and generating electricity by recycling wastes so as to make the industrial economy increase sustainable.

Abstract: The building of vehicle excellent quality and brand is actually the process in which building excellent brand is taken as the goal, and vehicle quality chain comes into being through the systematic planning and integrated control and scientific management of every links throughout the formation of vehicle excellent quality, including the quality of planning, design quality, procurement quality, manufacturing quality, logistics quality, information quality and other intermediary qualities and even customer perceived quality. The mechanism of creating excellent vehicle brand is just the operation mechanism of the vehicle brand-quality chain. From the perspective of building excellent vehicle brand, this paper raised the concept of Vehicle brand-quality chain and explored the characteristics of vehicle brand-quality chain operational mechanism.

Key word: Vehicle; Excellent brand; Quality and brand Chain; Operation mechanism

1 Introduction

21st Century is the century of the brand and quality. For the national pillar industry of the vehicle industry, core competitiveness stems from the advanced technical level, the enterprise reputation based on brand, and the reliability and stability of the credibility of specific product quality. In recent years, with the blowout of China's vehicle market, and self-owned brand vehicle also occupy a certain share among the fierce competition. However, compared with the opportunities brought by China's huge market scale, its developing speed is't ideal. Of course, there are many complex reasons. Concretely speaking, China's independent vehicle industry have paid too much attention to immediate interests. There is no system planning or long-term construction to technology innovation, excellent quality, hundred-year brand and famous brand. From the perspective of creating China's excellent brand of vehicle industry, with the study of vehicle quality chain and its operation mechanism, this article is to discuss the creation of excellent brand of vehicle.

2 The Connotation of Excellent Automotive Brand and Excellent Quality

2.1 The connotation of excellent automotive brand

Excellent vehicle brand refers to the comprehensive embodiment, which is based on well-known vehicle trademark, including product quality technical level, service level, corporate image and reputation of automobile enterprise. Creation of excellent vehicle brand lies in excellent vehicle quality.

2.2 The connotation of excellent vehicle quality

Excellent vehicle quality is relative to the usual standard of automotive quality which is just the minimum standard that must be met by all automotive enterprises. However, excellent vehicle quality, which is based on the usual standard of automotive quality, demands to carry out continuous quality improvement actively, and constantly surpass and get breakthroughs in quality. That is to say the excellent vehicle quality is a set of internal management system in enterprise, and much stricter than normal quality standard. ^[1]

The capacity of enterprise to offer long-term and zero-defect product and service to meet customer demands stably and reliably is the external representation of excellent vehicle quality, which also need give customers "surprise" sometimes exceeding their expectations, and achieve customer's satisfaction and increase their fervidity, thus building excellent brand.

2.3 Interactive triangle between excellent vehicle technology, excellent quality and excellent brand

As shown in Figure 1, creation of excellent brand aims at creating transcendent brand, and takes it as a guide to build excellent vehicle quality on the basis of excellent technology. Technical excellence need that enterprises increase technical inputs to accumulate automotive technology, and that enterprises

* This paper is supported by Chinese National Social Science Foundation for Young Scholars (09CJY049), and the Guangxi scientific research and technology development projects (10123003-5, 1298027-5).

introduce advanced technology to digest and absorb and realize innovation, and that enterprises integrate resource to form independent innovation achievements. Excellent vehicle quality lies in a system planning of quality and integrated control. With quality disposing, fast response, perfection and propulsion of quality system, enterprises could actualize continual improvement of vehicle quality.

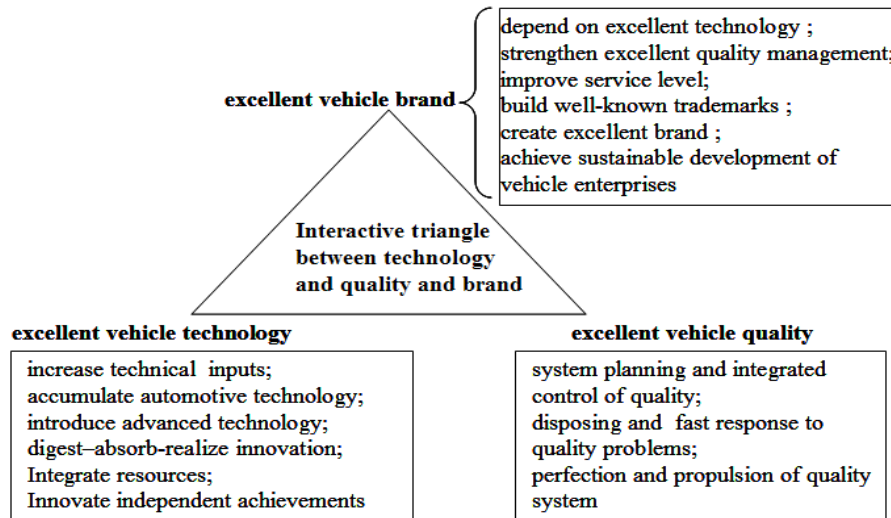

Figure 1 Interactive Triangle Between Excellent Vehicle Technology, Quality and Brand

3 Process of Creating Excellent Vehicle Brand—Vehicle Quality Chain

3.1 Bringing forward of the concept of quality chain

It was under the background of social production specialization, personalized customer demand and furious market environment that vehicle quality chain engendered. At the same time, quality chain also stems from the change of competition mode, which from free competition to cooperative competition, from the competition among individual enterprise into the competition among enterprise groups, from competition for corporate interests to competition for social responsibility. The earliest concept of quality chain was proposed by Columbia University of Canada (UBC) scholars.^[2]

3.2 The concept of vehicle brand and quality chain

Vehicle Brand and Quality Chain (“VBQC” hereinafter) refers under the background of open economic environment and global manufacturing system, the process of automobile industry manufacturing chain entity forming excellent vehicle quality. It is a quality chain taking automobile factory as main body, customer satisfaction as the core, creation of excellent vehicle brand as the goal through the control of products quality as well as collaboration with other quality chain subject. It is a fusion of scientific and compositive function chain which combines vehicle value chain and vehicle service chain and vehicle information chain.^[3]

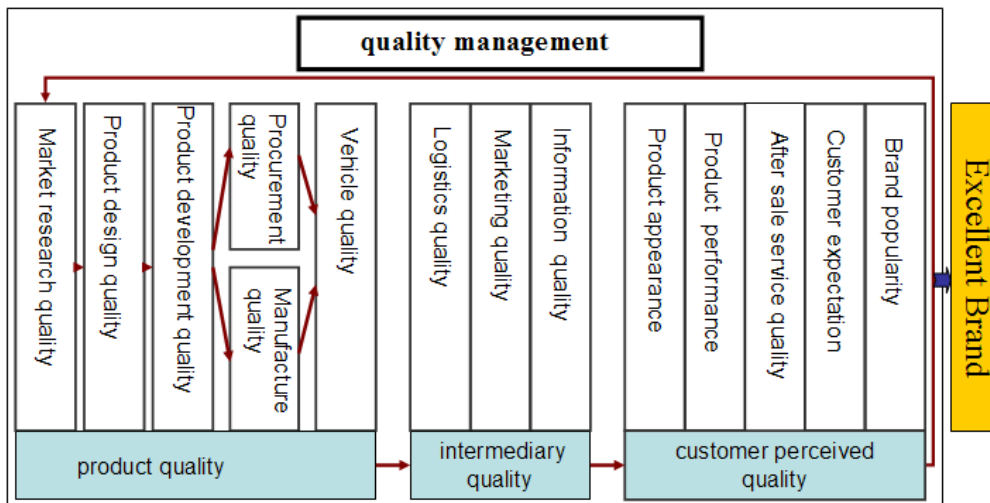

Figure 2 “VBQC”——From the Perspective of Formatting Vehicle Quality

The concept of “VBQC” could be concretely understood from two aspects. Firstly viewed from the perspective of formation of vehicle quality, “VBQC” consists of all business processes and working links related to vehicle quality. Vehicle quality starts from quality of market research, and then with quality of programming, development, procurement and manufacture, at last formatting vehicle quality. Vehicle quality evolves into customer perceived quality via intermediary quality, with management quality running throughout this period, as shown in Figure 2.

Secondly, from the perspective of vehicle product constituent, all node enterprises like automobile factory, suppliers, OEM, distributors and other external partners as a unified whole form a quality chain across enterprises boundaries. All node enterprises on the quality chain operate around the core of automotive product quality closely to control and coordinate quality, therefore formatting quality chain as shown in figure 3.

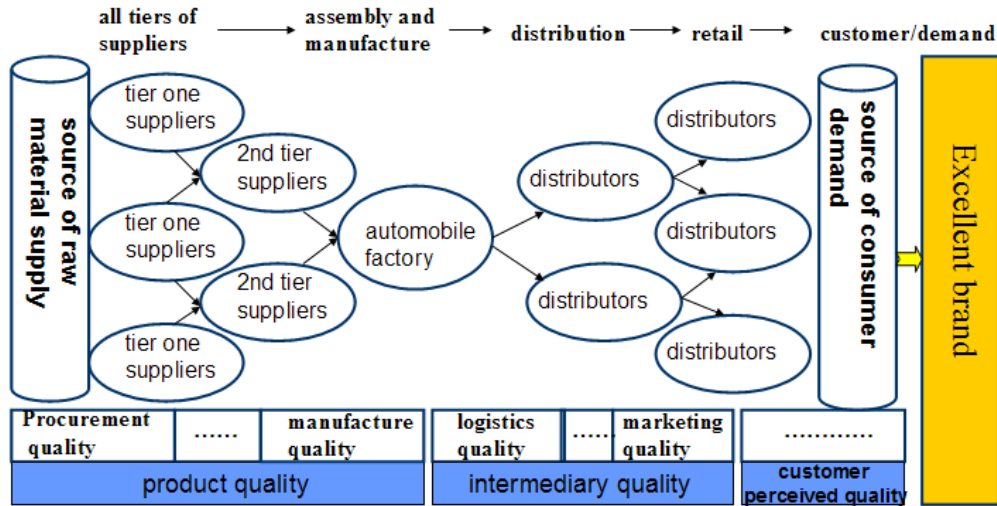

Figure 3 “VBQC”——From the Perspective of Constituting Vehicle products

3.3 Characteristics of “VBQC”

(1) Many main bodies. In the process of automotive products programming, design, production, sales to aftersale, there will be many different related main bodies such as automobile factory, suppliers of auto parts and raw materials, OEM, logistics providers, franchiser, service providers and so on. So the quality is coordinated and guaranteed mutually by all parties involved in the collaboration. Once any party provides quality which could not meet the requirements, the final quality of automobile products will be affected.

(2) Distributed characteristic. On one hand, characteristic of regional distributed of “VBQC” refers that because of the related node bodies especially suppliers, franchiser, service providers distributing in different regions, there is a somewhat differential spatial constraints between automobile factory with them.

(3) Transitivity. Quality problems in automobile factory, suppliers, logistics providers, franchiser, service providers will not only affects the quality of its own, but also will be transferred to the vehicle generally, even to the end customer. In the process of automobile quality formation and implementation, there is "Domino" effect obviously.

(4) Augment. Augment characteristic of “VBQC” means that losses caused by quality problem will continue to enlarge from upstream to downstream process, as shown in figure 4. Early-period quality is the foundation and guarantee of manufacturing quality of downstream manufacturing enterprises. Toyota’s recall events for problems of “Tramplng” and "Brake" is a profound lesson.

Figure 4 Augment and Transitivity of “VBQC”

4 Creating Mechanism of Vehicle Excellence Brand—Operation Mechanism of Vehicle Outstanding Quality Chain

4.1 The operation mechanism model of “VBQC”

The process of creating vehicle excellent brand is actually the vehicle outstanding quality chain management process of the strict control and management in every aspect of the vehicle quality formation, which takes creating excellent operation brand as the ultimate goal. [4]Creating mechanism of excellent vehicle brand is actually the operation mechanism of “VBQC”. Vehicle outstanding quality chain often takes automobile factory as the core enterprise and its operation mechanism is shown in figure 5. Vehicle product quality is the vector and core of vehicle quality. Vehicle product quality is composed of the quality of planning, design, procurement and manufacturing and delivered to the client through the intermediary quality forming the customer perceived quality. If the actual quality can be in the upper limit of the standard or even beyond standard quality of the long-term, it will receive good customer perceived quality, forming excellent quality, casting customer enthusiasm, thus creating excellent brand .Of course, the implementation of superior quality and excellent brand also requires the quality of management throughout the process to provide protection and support; conversely, if the actual quality is below the standard quality, the risk of product quality problems may exist. Once the risk quality exceeds a certain range, the risk will be converted to deterministic defect and cause the defect quality.

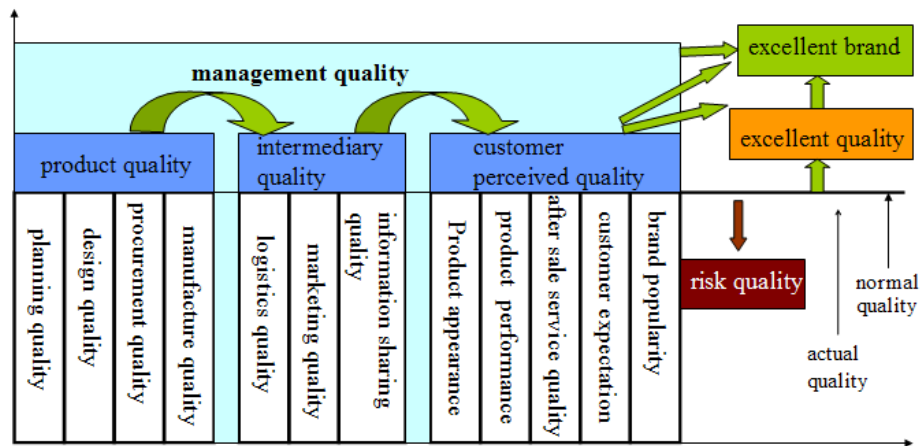

Figure 4 Creation Mechanism of Vehicle Excellent Brand—the Operation Mechanism of “VBQC”

4.2 Management and collaboration of “VBQC”

Vehicle Outstanding Quality Chain Management (“VOQCM” hereinafter) is taking the vehicle manufacturers as the core business, integrating the entire life cycle of the vehicle products from planning and design, manufacturing to sales and service into the main responsibility for quality of vehicle outstanding quality chain, driven by the common quality objectives ,through the specification and control of the subject behavior and the sharing of quality information and the full collaboration between organizational elements to ultimately achieve the whole process of integrated control and management of superior brand. “VOQCM” is the management of the specific implementation in the enterprise of the operating mechanism model of “VBQC”, to achieve superior quality through the various elements quality in the planning, implementation, control and measurement improvement to achieve the stable actual quality which is beyond the standard quality.

“VOQCM” aims at collaborative management of vehicle quality between the relevant parties, namely taking full participation as means, common interests as base, mechanisms for sharing of information resources, integrated use of technology and management and other means as pattern to achieve integration of information, processes, resources and other elements from node enterprises which is to create a open, sharing and cooperative working model. Finally, both production and business will be synchronous between enterprises, as well as strategy and objectives, so that substance and energy could be exchanged smoothly between organization and environment. In short, “VOQCM” builds a quick, smooth, controlled and optimized quality chain among the supplier, manufacturer, franchiser and end user through the control and sharing of automobile quality information. It targets customer satisfaction and excellent brand creation in order to enhance the core competitiveness of enterprises and the whole supply chain. [5]

The collaborative “VOQCM” requires: ① to base on the theory of system theory, coordination theory and integration theory, simultaneously effectively combined with the theory of quality management; ② to achieve effective integration of information flow, workflow, logistics, value flow and cost flow through quality flow; ③ to always adhere to the core of customer satisfaction, the pursuit of excellence in quality, the goal to create excellent brand, the main line of resources integration and quality control, the means of sharing information technology; ④ to realize continuous improvement of vehicle quality through the full participation and continual improvement.

5 Conclusions

Creating excellent brand is a rough task for China’s vehicle industry. It is essential to establish excellent vehicle quality which is also the strong backing and core connotation. Complete systematic analyses of “VBQC” are momentous to form excellent vehicle quality. It is necessary to research the operation mechanism of “VBQC” on the basis of mentioned analyses in order to achieve integrated control and collaborative management of automobile quality so that satisfy or even exceed customs’ expectation and build brand.

Research on Identification of Core Competence of Disruptive Technological Innovation Network Partners

Sun Shenglan

School of Medical Business, Guangdong Pharmaceutical University, Guangzhou, P.R. China, 510006

(E-mail: sunsl2005@163.com)

Abstract: Disruptive technological innovation is a new research field which is different from the traditional technological innovation and has become the main power to push the continuous economic development worldwide, especially in the developed countries. It has been a significant theoretical and practical issue since in 1997. During the process of disruptive technological innovation, partner selection is an important problem and the identification of core competence of network partners is directly related to its effectiveness and success. Considering the fuzziness involved in the identification of core competence of disruptive technological innovation network partners, this paper proposes to identify the partners' core competence by using fuzzy cluster method and constructs model of core competence of network partners, which aims to provide scientific basis and method for enterprises' successful disruptive technological innovation.

Key words: Disruptive technological; Innovation network; Network partners; Core competence; Identification

1 Introduction

The concept of disruptive technological innovation has become a popular topic in both academic circles and mainstream press since its introduction in 1997 by Clay Christensen in *The Innovator's Dilemma* (Christensen, 1997). According to Christensen, a disruptive technological innovation initially appeals only to fringe customers, but eventually improves the dominant technological that had been long used by mainstream customers (Christensen, 1997; Tellis, 2006). One of Christensen's main contributions was the discovery that new entrant firms tend to have more success with the emergence of disruptive technological innovation than incumbents (Christensen, 1997; Henderson, 1993). The reasoning for this claim is that incumbents tend to invest more in incremental innovations that build off of their previous products while new entrants were more likely to invest in disruptive innovations. Henderson (1993) found that incumbents may be saddled by their assets. Furthermore, incumbents have likely already developed effective routines for handling their customers. Conversely, new firms are not constrained by prior competencies and are more able to take advantage of technological opportunities (Tushman & Anderson, 1986). For example, new entrants appear to be advantageous as they are generally more flexible in resource allocation.

With the rapid development of technological and the accelerated globalization process, disruptive technological innovation has become the main driving force for sustainable economic development of a country, which can make countries, regions or enterprises lagging in technological have a chance to compete with those who advanced technological in the same starting line, even surpass them. With the advent of the era of knowledge economy and the rapid development of information technological revolution, the importance of the innovation network is increasingly apparent, and will become the organization form and strategic choice that enterprises will take in technological innovation activities. The most basic reason to construction of technological innovation network is that the finiteness of the enterprise innovation ability and the resources scarcity. It is impossible that any enterprise is equipped with technological innovation ability in all the required fields. Enterprises which carry out disruptive technological innovation is no exception. As Christensen points out, needed resources of disruptive technological innovation activity should gain from consumers needed disruptive technological and investors willing to invest, rather than merely from the original organization. Therefore, the identification of core competence of disruptive technological innovation network partners is a major project. When distinguishing our partners' core capability of enterprise, we can't judge accurately if a partnership enterprise have one kind of core competence or do not have another core competency, but can only judge if a partner companies has some kind of core competence to some extent. It is easy to make out that the problem of fuzzy properties is obvious, while the fuzzy clustering analysis can solve the problem of the unclear boundaries.

2 Problem Description

Generally speaking, the integration object of enterprise innovation network can be divided into three categories: resources, knowledge and technological. Because of this, we can base on the perspective of resources, combine with the related network theory, and construct the disruptive technological innovation network which is made up of the lead users, suppliers, universities, other stakeholders, venture capital firms and so on. Assumes that each partner has a core competence. Therefore, we need to identify core competence of all disruptive technological innovation partners.

Through the way of online bidding, the enterprises implementing disruptive technological innovation have determined (including itself) n identified enterprises X_1, X_2, \dots, X_n , and arranged decision committee to investigate the identified enterprises from the index m . Firstly, according to the index data provided by the identified enterprises and their experiences, decision makers make a comment on the identified enterprises $X_k(k=1, 2, \dots, n)$ from characteristic indexes m . It is written as:

$$X_k = (x_{k1}, x_{k2}, \dots, x_{km}) \quad k=1, 2, \dots, n.$$

Among them, the x_{kj} ($k=1, 2, \dots, n; j=1, 2, \dots, m$) is the symbol for the characteristic evaluation value of the identified enterprise X_k about number j . So, for the characteristic evaluation value of the identified enterprise n , the characteristic matrix is denoted as:

$$X_{n \times m} = (x_{kj})_{n \times m} = \begin{bmatrix} x_{11} & x_{12} & \dots & x_{1m} \\ x_{21} & x_{22} & \dots & x_{2m} \\ \dots & \dots & \dots & \dots \\ x_{n1} & x_{n2} & \dots & x_{nm} \end{bmatrix}$$

At the same time, we assume that members of the network partners of disruptive technological innovation has broken down into partners s , each partner has a core competence correspondingly V_1, V_2, \dots, V_s , each core competence V_i ($i=1, 2, \dots, s$) corresponds to a cluster center, i.e

$$V = \{V_1, V_2, \dots, V_s\},$$

According to past experience, Decision makers make a comment on each cluster center from the index m , denoted by:

$$V_i = (v_{i1}, v_{i2}, \dots, v_{im}) \quad i=1, 2, \dots, s.$$

Among them, the v_{ij} ($i=1, 2, \dots, s; j=1, 2, \dots, m$) mean that decision makers make a evaluation to core competence V_i about characteristic indexes j . As a result, characteristic matrix of each cluster center is written as :

$$V_{s \times m} = (v_{ij})_{s \times m} = \begin{bmatrix} v_{11} & v_{12} & \dots & v_{1m} \\ v_{21} & v_{22} & \dots & v_{2m} \\ \dots & \dots & \dots & \dots \\ v_{s1} & v_{s2} & \dots & v_{sm} \end{bmatrix}$$

Determined the evaluation value of characteristic index of each identified enterprise and core competence correspondingly, decision makers need to synthesize these information to determine the core competence identified enterprise. There is s kind of core competence, which corresponds to the s membership degree, denoted by:

$$U = \{U_1, U_2, \dots, U_s\},$$

U_i ($i=1, 2, \dots, s$) means vector which are made up of membership degree of core competence no. i of all identified enterprises, denoted by:

$$U_i = (u_{i1}, u_{i2}, \dots, u_{in}).$$

Among them, $u_{ik} \in [0, 1]$ ($i=1, 2, \dots, s; k=1, 2, \dots, n$) means that the membership degree of core competence no. i of identified enterprise X_k . In this way, we can obtain membership degree matrix of core competence s of identified enterprise n , is written as :

$$U_{s \times n} = (u_{ik})_{s \times n} = \begin{bmatrix} u_{11} & u_{12} & \cdots & u_{1n} \\ u_{21} & u_{22} & \cdots & u_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ u_{s1} & u_{s2} & \cdots & u_{sn} \end{bmatrix}$$

3 Algorithm Description

Based on the description of the problem, we can learn about the value of characteristic matrix of unidentified enterprises, $X_{n \times m}$, the value of characteristic matrix of cluster center, $V_{s \times m}$, and the constitute condition of membership matrix, $U_{s \times n}$. Next, we are going to make a detailed description about the specific algorithm.

First of all, initializing the value of characteristic matrix of cluster center $V_{s \times m}^0$ and the membership matrix $U_{s \times m}^0$

As we know, fuzzy clustering algorithm is an iterative process. Therefore, we should confirm the initializing the value of characteristic matrix of cluster center $V_{s \times m}^0$ and the membership matrix $U_{s \times m}^0$. According to the description of the issue above, the initialized $V_{s \times m}^0$ and $U_{s \times m}^0$ separately are:

$$V_{s \times m}^0 = (v_{ij})_{s \times m}^0 = \begin{bmatrix} v_{11}^0 & v_{12}^0 & \cdots & v_{1m}^0 \\ v_{21}^0 & v_{22}^0 & \cdots & v_{2m}^0 \\ \cdots & \cdots & \cdots & \cdots \\ v_{s1}^0 & v_{s2}^0 & \cdots & v_{sm}^0 \end{bmatrix}$$

$$U_{s \times n}^0 = (u_{ik})_{s \times n}^0 = \begin{bmatrix} u_{11}^0 & u_{12}^0 & \cdots & u_{1n}^0 \\ u_{21}^0 & u_{22}^0 & \cdots & u_{2n}^0 \\ \cdots & \cdots & \cdots & \cdots \\ u_{s1}^0 & u_{s2}^0 & \cdots & u_{sn}^0 \end{bmatrix}$$

Among them, $V_{s \times m}^0$ is the characteristic matrix, which components of the initial judge of core competence s from index m by decision makers; as for $U_{s \times m}^0$, it is the initial membership estimation made by the decision makers towards unidentified enterprises n attached to core competence s. They will be iterated by certain regulations in the following steps.

Step 2, iterate the membership matrix attached to core competence V_i of the unidentified enterprises X_k .

To iterate the membership matrix attached to core competence V_i of the unidentified enterprises X_k , that is to say confirming the figure of u_{ik} ($i=1, 2, \dots, s; k=1, 2, \dots, n$) in the matrix. Here, the relative distance between unidentified enterprises X_k and core competence V_i represent the membership attached to core competence V_i of the unidentified enterprises X_k .

$$u_{ik} = \frac{1}{\sum_{j=1}^s \left(\frac{|X_k - V_i|}{|X_k - V_j|} \right)^{\frac{1}{r-1}}} \tag{1}$$

From the formula(1), It is not hard to see that the closer between the unidentified enterprises X_k and the clustering center V_{ij} , the more the membership u_{ik} attached to core competence V_i of the enterprises. That is to say, it is very clearly show that the enterprise has core competence V_i . R is any positive integer

in the formula(1), in general, $r=2$.

Step 3, iterative the value of characteristic matrix of cluster center, $V_{s \times m}$

To iterate the value of characteristic matrix of cluster center, $V_{s \times m}$, that is to say confirming the figure of v_{ij} in the matrix. According to step 2, we can get the figure of u_{ik} . Therefore, we can solve characteristic value v_{ij} of cluster center i about j .

$$v_{ij} = \frac{\sum_{k=1}^n (u_{ik})^r x_{kj}}{\sum_{k=1}^n (u_{ik})^r} \quad \begin{array}{l} i = 1, 2, \dots, s; \\ j = 1, 2, \dots, m. \end{array} \quad (2)$$

R is any positive integer in the formula (2), in general, $r=2$.

4 Conclusion

With the rapid development of technological innovation, the general trend of the enterprises' innovation is transforming from an incremental pattern to a disruptive pattern. In today's society, disruptive technological innovation has become the main driving force for sustainable economic development of a country, especially of the developed countries. During the process of disruptive technological innovation, the identification of core competence of network partners is directly related to its effectiveness and success. Generally speaking, the identification of core competence of network partners is a process of combining qualitative and quantitative analysis. At present, using quantitative analysis method is a mainstream method when we are reseaching the identification of core competence of network partners. In this paper, based on the former work done by the author, the practicality of fuzzy cluster analysis method has been further studied. Core competence of disruptive technological innovation network partners are identified by fuzzy cluster analysis method.

The author applied the fuzzy cluster analysis method to the identification of core competence of disruptive technological innovation network partners, and considered the characteristic of the fuzzy involved in the identification of core competence of enterprise partners. Using this fuzzy cluster method to identify the partners' core competence, is much more close to life, fits our learning way as well as makes the judge result more objectives and dependable. Using this method, to some extent, can enhance enterprises' success rate for implementing disruptive technological innovation.

Product Architecture Embedded in Mobile Internet: An Exploratory Study*

Yu Yan, Gu Yuanxun

School of Economics and Management, Beijing Jiaotong University, Beijing, P.R.China, 100044

(E-mail: yuyan0219@126.com, yuanxungu@gmail.com)

Abstract: There are a lot of Mobile Internet products arising with the development of Mobile Internet. Product architecture has an important effect on product's development process. This paper takes WeChat as an example to study the product architecture embedded in Mobile Internet. Combining with the different characteristics of Mobile Internet product, we build a logic framework for product development which classified the development into three phases: analysis, product design and adjustment. After contrastive analysis, we make a conclusion that product architecture embedded in Mobile Internet should focus on the combination of flexibility with various functions. Modular architecture and "Prepare for the future" product architecture decision are more effective.

Key words: Component; Mobile Internet; Product architecture; Contrastive analysis

1 Introduction

With the rapid development of Mobile Internet, the number of Mobile Internet products grows gradually. Kik is a very important part of Mobile Internet products. Under the rapid development and fierce competition, many companies pay sustainable attention on how to make competitive mobile internet products through effective product architecture at strategic level.

Product architecture is a process of mapping product functions onto physical components and the interaction among these components through specified interfaces (Ulrich, 1995; Sanchez, 1996).

Product development process can be viewed as consisting of three phases: analysis, product design, and adjustment.

Figure 1 Product Development Process

The analysis phase concerns the identification of function and flexibility requirements as well as the mapping from functional elements to physical components. The function and flexibility requirements are based on technology situation analysis, customers' needs, and competition environment and so on.

The product design phase includes two main parts: selection of the product architecture type and choice of product architecture decision way. There two types of product architecture: modular architecture and integral architecture. Modular architecture includes a one-to-one mapping from functional elements in the function structure to the physical components of the product, and specifies de-coupled interfaces between components. Integral architecture includes a complex (non one-to-one) mapping from functional elements to physical components and/or coupled interfaces between components (Ulrich, 1995). There are four categories of product architecture decision: "Include in all", "Exclude", "Prepare" and "Do nothing". "Include in all" means to include the features in all units of the product but disabled once the market requires the feature. The firm can launch it very fast and gain a good market share. "Prepare for the future" is to build a preparation form into the product. If the market requires it, the time to market will be short. "Exclude in all" exclude a particular feature deliberately, however, the consequences can be so drastic that it is impossible to redesign the product and include the feature in the future. "Do nothing" means do not prepare for the possible feature but without excluding the possibilities for offering the feature (Marc Wouters, Mark Workum and Paul Hissel, 2011).

* This paper is supported by the Fundamental Research Funds for the Central Universities (No.2013JBM027)

The adjustment which is based on product test and gap analysis includes the change during a product's lifecycle and the change across generations of the product (Ulrich, 1995). The adjustment also concerns the change of components or/and interfaces. Henderson and Clark (1990) classified innovation into four categories: incremental innovation, modular innovation, architectural innovation and radical innovation. They classified them as two dimensions. The horizontal dimension captures an innovation's impact on components, while the vertical captures dimension its impact on the linkages between components.

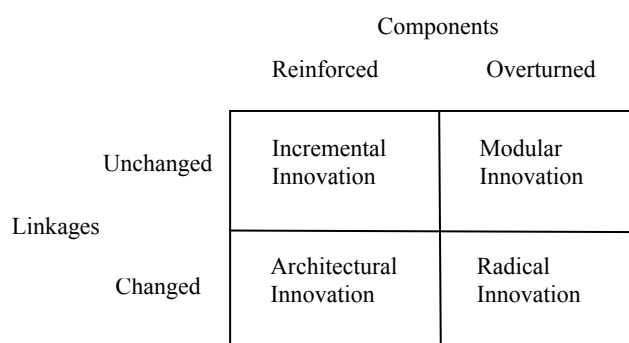

Figure 2 A Framework for Defining Innovation

On the whole, product architecture is of strategic importance for firms (Fixson, 2005, 2007; Gil, 2007). It plays an important role in a product's development process and helps corporate design and update products.

2 Mobile Internet Applied in Social Communication

2.1 The status of mobile internet industrial development

From a global perspective, with the rapid development of Mobile Internet, the network continues to upgrade. The penetration rates of Mobile Internet in Japan and Korea are higher than those in other countries.

Japan's Mobile Internet development is one of the fastest. Its development depends on the co-ordination with the industrial chain, especially with the mobile communication operators and the financial industry, which is of significance on China's Mobile Internet development (Hao Enduo, 2010).

In the process of analyzing the domestic Mobile Internet development, operation mode, specialty applications, and respond to market competition, scholars point out that the main problems in the development include bandwidth, terminals, platforms, applications, industry chain and so on (Lu He, 2009).

2.2 The status of mobile Internet based social communication products and services

Table 1 Comparison among Kik Products

Products	Advantage	Disadvantage	Time	Company
Michat	Launch in the head Technical support Humanized function	Grassroots No user base	December,2010	Xiaomi Tech
WeChat	Huge QQ user base	Coordination between making friends and keep privacy	January,2011	Tencent
Youni	Reliability of Short message model and protection of users' privacy	No recommendation No combination with game player Limited users source	April,2011	SDTH
Kouxin	Technical support comprehensive function unique group share function	No motivation for user to use 360 ID, which lead to small user number	August,2011	360
Woyoo	First to initiate among three operators Have cell phone user base	Unstable function Message delay imperfect User experience	August,2011	China Unicom
Fechat	Free internet fee among Feiliao users	Mobile user only	September,2011	China Mobile
Yichat	Regardless of operator E-surfing user base Completely free	Late release time Seize the market chance	October,2011	China Telecom

On October 2010, Kik message had been launched. Although Kik is very easy to use, it is own the function of both efficiency and effectiveness. Products like Kik have many features such as simple, timely and cheap, Kik users do not need face to face, they can fully aware that whether the information reach the other party and whether there has feedback (Sheng Jia, 2011). Products like Kik also began to appear in China, such as WeChat launched by Tencent, Michat launched by Xiaomi Tech, Youni launched by SDTH and so on. Table 1 is a comparison among various types of Kik products.

3 Case Analysis and Suggestions

WeChat, as one of the successful Mobile Internet products, is worth studying. Taking WeChat as an example, this paper aims at realizing the strategic significance through analyzing the product architecture of WeChat.

3.1 Profile of WeChat

WeChat, created on January 21st, 2011, is cell phone chatting software via the Internet. There are many functions, such as sending sounds, video, picture, words as well as supporting group chat among people. Users can keep in touch in rich forms through WeChat. WeChat is completely free of charge, which means any function will not be charged. The Internet flow fees generated in the process of WeChat is paid by network operator. By late March in 2012, WeChat users have broken 100 million users in 433 days. On September 17th, 2012, users have broken 200 million in less than 6 months. By January 24th, 2013, users are amount to 300 million in less than 5 months. The trend is on the way.

“WeChat Speed” is becoming an industrial topic under the age of Mobile Internet. WeChat is not originally created by Tencent, but the primary form of a foreign company, named Kik. The similar softwares also have MiTalk, MoMo and so on. Among these softwares, MiTalk is earlier than WeChat on line, but at a slower development speed. WeChat versions, from 1.0 to 4.5, always surprise users at every version updating. With regard to WeChat’s success, the innovative function and perfect user experience are the trump card except Tencent’s powerful social relation chain.

In terms of functions, WeChat can send voice messages, pictures and media information, which only spends Internet flow without paying any fees. “Look around” and “Shake” are two hotspots in WeChat. The growing number of new users at a high speed establishes absolute statue in mobile App market. WeChat also introduces LBS social function and another two functions related to geographic location, namely “Seek for friends around you” and “Drift bottle”, which enlarge the applied range of WeChat from friends to strangers, as well as maximize the mobile features of phone. In 4.2 versions, WeChat adds another two functions named “Video chat” and “Web WeChat”. In 4.3 versions, WeChat introduces a function called “Shake to send pictures”. For WeChat users, they often have one or two memorable points of WeChat in every version. WeChat’s frequent upgrading shows its special innovation.

3.2 Analysis and suggestions

The success of WeChat lies in its outstanding product as software, combing market need with technological factor in the process of its product architecture. Table 2 is WeChat’s iphone version.

The chart shows that since WeChat is online, its functions are improving with the updating version and users experience continues to enhance. In other words, WeChat’s progress is realized by the changes across generations of the products. Each version is a generation of WeChat, which means new functions have been added into new version or original functions will be perfected in new versions.

On another side, the basic idea of WeChat’s product architecture is the transformation from ordinary Mobile Internet chat software to a basic platform. This platform enhances the flexibility and effectiveness with combining various functions and technology. Through this platform, companies can open up users’ resources and relation chain. Entrepreneurs focus on how to provide goods or service for users, not how to manage or sale the product. A series of problem, such as the stability of server, the abundance of bandwidth, the speed of operational capability, the security of users’ privacy, can also be solved through this platform.

In detail, WeChat’s product architecture finds out the most valuable factors and pay attention to them. First, the Mobile Internet brings two things differing from PC. There are location information and real-time online. However, Mobile Internet product also cannot switch among many functions smoothly just likes PC. Thus, WeChat have to think about how to construct a product which has better user experience with the environment change. Second, an important feature of Mobile Internet product which WeChat should know is the fact that one App can only do one thing. For WeChat, communication is the basic function, so how to make this function and related functions work well is a key part for WeChat’s

product architecture. At last, in terms of product architecture, an ideal product is to satisfy the major demand of user within one page, like Facebook, Twitter. The study shows that most users intend to focus their things within two pages. Therefore, WeChat need to consider how to organize product to realize its value in two pages after user open WeChat (Shu Xun, 2013).

Table 2 WeChat's Iphone Version

Version	Time	Function
1.0 for iPhone(beta version)	01/21/2011	
1.1 for iPhone(beta version)	03/10/2011	Interflow with Tencent microblog private letter
1.2 for iPhone(beta version)	03/21/2011	Support Group chat
2.0 for iPhone	05/10/2011	Add Talkback function
2.5 for iPhone	08/03/2011	Support video and Look Around
3.0 for iPhone	10/01/2011	Support the function called Drift bottle and Shake. Support Traditional Chinese language interface Support users from Hong Kong, Macao, Taiwan, USA and Japan to bind cell phone number
3.1 for iPhone	10/27/2011	Support English interface display
3.5 for iPhone	12/20/2011	Support text message register among over 100 countries
4.0 for iPhone	04/19/2012	Add photo album function
4.2 for iPhone	07/19/2012	Add video chat plug-in board Add web version for WeChat
4.3 for iPhone	09/05/2012	Add a new function called send picture by shaking Add voice search WeChat number can unbind QQ number and cell phone number
4.3.2 for iPhone	10/30/2012	Overall Compatibility for iPhone 5

4 Contrastive Analyses

Product architecture plays an important role in many industries such as automotive industry, machinery industry, electronics and the software products (Gu Yuanxun, 2012). For WeChat, functions such as “Voice chat”, “Look around”, “Shake” can be regarded as components. The linkages among those components are interfaces. The process of WeChat’s development can be divided into analysis, product design and adjustment phase.

4.1 Analysis

The first step for product development is to analysis the technical environments, customer requirements, state of market competition, etc. After the analysis, companies found out desired functions, especially core functions, as well as flexibility requirements, and then mapped those functions onto components. For WeChat, the basic function is communication; this function has been mapped onto components such as Voice Chat, Emoticons and Group Chat. WeChat is a social communication App based on Mobile Internet which has the typical characteristics of Mobile Internet products, it must meet users’ personality demand and take the rapid development of such applications into account, so the flexibility requirement is high.

4.2 Product design

During the product designing phase, corporate should choose the product architecture approach and decision way. Modular architecture can enhance flexibility and improve customer’s satisfaction, while integral architecture may exhibit higher performance. In fact, most products, including WeChat, will embody hybrid modular-integral architectures (Ulrich, 1995). WeChat’s basic function about communication is integral architected, functions such as “Shake”, “Look Around” are separately designed as a plug-in for users to install.

According to the patient table case study (Marc Wouters, Mark Workum and Paul Hissel, 2011), the product architecture decision of “Exclude” is always effective, while “Prepare” is hardly favorable. But for Mobile Internet products, “Prepare” would be the best solution which saves launch time and redesign costs. WeChat is continuously updating, each version of the updating can be seen as the redesign based on the original version. Managers will decide whether to launch the new functions after they analyze the markets and outweigh the costs.

4.3 Adjustment

The product's adjustment and upgrade is the key to success. WeChat's iPhone version shows that the main change of WeChat is adding new functions by version update. But the change is not only to add a new plug-in, but also to combine with other industries. In May 2012, WeChat launched the "scanning" function and try O2O marketing mode through two-dimensional code. In addition, WeChat incorporates with banks, hotels and so on to provide many applications such as check road conditions, check credit cards, booking hotels, booking takeaway, tickets, etc. These extensive functions of WeChat both attract more users and enhance user stickiness. The adjustment and upgrade requires WeChat to build a basic platform which support the new components to be added in and the interface to be changed.

5 Conclusions

Product architecture has an important effect on product's development process. This paper builds a logic framework for product development and lists key points of each phrase.

When product architecture is embedded in Mobile Internet, new features emerge. It needs increasing focuses on the combination of flexibility with various functions. The function has been enhanced and expanded by the addition of plug-ins. So modular architecture will be more useful when each plug-in is regard as a module. Mobile Internets products change quickly and they are more common across different generations. The product architecture decision "Prepare" is more effective because it is always quicker.

There are several limitations and future research opportunities. This paper makes an overall framework for product development but lacks some research in depth. Future research could focus more effectively on how the Mobile Internet product will be able to incorporate new functions and various industries.

Technology Diffusion of Cloud Computing

Tiina Liimatainen, Yang Liu*

Department of Production, University of Vaasa, PL 700, 65101 Vaasa, Finland
 (Email: liimatia@gmail.com, yli@uva.fi)

Abstract: This paper (1) presents background and technical framework of cloud computing; (2) introduces innovations, technology diffusion and reasons that intensifies diffusion; (3) represents the technology diffusion enablers in relation cloud computing; (4) defines opportunities; (5) address challenges and finally sets out (6) conclusions.

Key words: Cloud Computing; Technology Diffusion; Innovations

1 Introduction

Cloud computing has become one of the most discussed topics in today’s IT organizations. Rather than having massive server farms, companies look for cost savings, cost avoidance and effectiveness by utilizing services based on cloud computing. Especially SaaS (software as a service) solutions have increased greatly and they are in many companies replacing the traditional on premises application environments.

When analyzing how technologies are being adapted, technology diffusion is one of the key elements. From technology diffusion perspective cloud computing is well adopted on the market but not yet a dominant design. Various technical and especially privacy related challenges need to be still addressed. Additionally, there are lots of legacy systems and legacy installations which may stay live still for several years. The cloud services become tempting often when selecting a new solution or when the support for the existing hardware or software elapses.

2 Background and Technical Framework

2.1 Development towards cloud computing

Roots of cloud computing are back in 1960s when computer sharing was discussed for the first times. Discussion intensified again when dotcom bubble was burst in early 2000 and investments got scarce. On mean to reduce costs was to reconsider sharing computing capacity as servers had overcapacity. Systems were prepared for usage peaks which seldom occurred. Hence leasing extra capacity out became tempting. Amazon’s Web Services (AWS) start up in 2002 is considered the beginning of cloud services.^[1]

2.2 What is cloud computing?

Reese sets out three criteria which defines if a particular service is a cloud service:^[2]

- (1)The service can be accessed via a web browser or web services API.
- (2)No capital expenditure is required to get started.
- (3)You pay only for what you use as you use it.

In cloud computing the software and hardware resources are delivered as a service over a network, typically the Internet. The name comes from the use of cloud-shaped symbol as an abstraction.

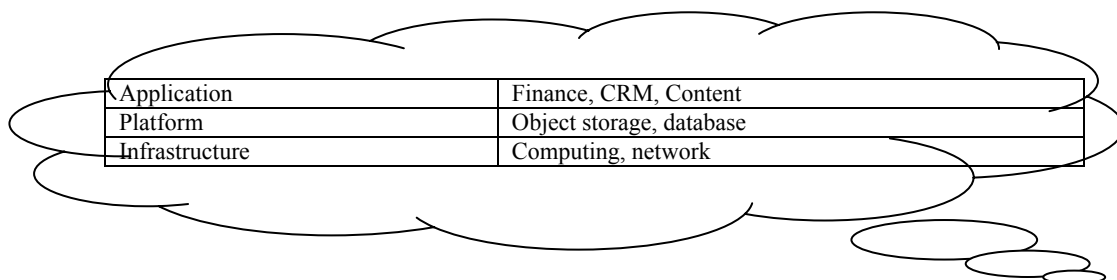

Figure 1 Cloud Computing

Figure 1 shows the layers of cloud computing. Software has an important role as the application layer provides the biggest value to the end user. The business logic resides on the application layer.

2.3 Service provisioning

Cloud services can be defined into three categories in relation to service provisioning:^[1]

Platform as a Service (PaaS) means the service provider has virtual servers from which the customer gets services as needed. In this model the customer can build his own applications by using predefined APIs. The computing comes from the cloud. An example of a PaaS is Google's development environment which enables development for applications to be run on Google's AppEngine service.

In Infrastructure as a Service (IaaS) the service hosts a virtual server base and gives predefined amount of computing power to customers. The customer installs his own operating systems and applications into these predefined segments. Well known IaaS service is Amazon Web Services.

Software as Service (SaaS) means the customer uses only the application, everything else from computing to the data storages is managed by the service provider. There are lots of SaaS providers. One of the most known is Salesforce.com who provides several cloud based solutions for CRM (customer relationship management) usage. SaaS is the biggest growing area in cloud computing era as it enables quick application deployment without one time deployment costs coming along with server and connectivity equipment purchases which would be required for stand-alone in-house systems.

2.4 Accessibility

Another way to classify the cloud services can be done by the accessibility: ^[1]

Public cloud means that the capacity is set out freely to anyone and it is not dedicated to any customer. The payment model is subscription based on time or on capacity. Private cloud is a company specific cloud which utilizes its own LAN. It does not require an internet connection outside. The operating and maintenance costs are carried out by the customer who also maintains the operating environment.

Public and private clouds can be connected to a hybrid cloud. Hybrid cloud means that company's private cloud is connected to a public cloud via internet connection.

3 Technology Innovations

Innovations can be segmented on radical innovations and on incremental innovations. ^[3] Cloud computing is considered to be an incremental innovation which utilizes the existing technology elements in a new way. The cloud implementation itself may include radical innovations but to end customer the services looks mostly the same.

The rate of technology performance and the rate at which the technology is adopted in the marketplace have been shown to conform to an s-shape curve. These curves are related as improvements in technology may foster faster adoption and greater adoption fosters further investments in performance improvement. ^[3]

Technology diffusion means technology adaptation in the marketplace. ^[3] Technology diffusion can be also presented by an s-shape curve which plots cumulative number of adopters against time. In the beginning the adoption pace is slow but as the technology becomes known in the marketplace, it accelerates. Finally the pace saturates as the rate of new adopters decline. S-curves in technology diffusion are in part a function of s-curves of technology improvement: when technologies are further developed, they become more secure and useful to users, facilitating their adoption. ^[3] As learning curve and scale advantages accrue to the new technology, the price of finished goods reduce which again attracts new users. ^[3]

Even if new technologies may be much better compared to the new ones, they often fail to attract the users and can be deployed only to a niche market. One major reason behind may be the complexity of the knowledge underlying new technologies, and the lack of complementary resources that make those technologies useful. Many potential users may not adapt new technology until the technology is available to them. ^[3] Cloud computing in its best is not visible to the end users but it affects application developers and IT organizations heavily. Making technology available to them is crucial.

Technology diffuses through international trade and international R&D ventures by multinational corporations. Developments in software technology and sharing of R&D investments have fostered this process. The future trend is to increase knowledge diffusion of technology. The competition for new processes and products has been intensified lately due to trade globalization and markets expansion. ^[4] Cloud computing itself can act as a knowledge diffuser; it eases the knowledge and knowledge sharing globally in a cost effective manner.

A change in the technology indicates a change in the production or in relation to the costs. In general technology includes all the knowledge and innovations needed to the production and distribution process. ^[4]

Technology generates multiple changes that affect the long term growth of an economy. In the

upward shift it improves the productivity of inputs like labor or capital following by reduced unit costs. Cost reduction helps to improve the profits and decreases the costs. ^[4]

Additionally, technologies help to expand the scale of production and enables further globalization and market expansion.

Innovation efficiency changes technology at the various points of value chain, thus challenging the companies to compete in new innovative ways. Successful companies transform their technologies to create new strategic assets which bring them more cash flows and new projects. This enables further investments and growth. ^[4]

Especially the latter is something cloud computing certainly helps; it enables companies better to focus their operations to competing edge rather than using capital and resources on ongoing services which in principle keep the current activities on the existing level.

4 Technology Diffusion Enablers

Adaption to the market requires the product or the service needs to be commercially attractive. In addition to commercial requirements proper technology diffusion requires the technological and functional needs to be fulfilled. Technology enablers make the commercial deployments possible.

4.1 Functional enablers ^[5]

There are four cornerstones which are to be fulfilled in order to reach adequate quality of service level:

(1)Efficiency: Execution and coordination of services are optimized in terms of data traffic and latency. Data traffic carries a big cost element with it, and therefore reducing that carrying cost is a long term goal. Latency can affect a lot in customer satisfaction and therefore needs to be watched carefully.

(2)Scalability: Cloud platforms can be connected by massive amount of people. Ability to work during burst hours is crucial.

(3)Robustness: The systems are to be designed for high availability with effective use of failover and graceful failover.

(4)Security: Proper security provisions must exist for both the applications and the data to protect service providers as well as consumers for intentional misconducts or malicious actions.

4.2 Commercial enablers

IT projects or services whose mission not to go beyond helping the business “stay with the race” or on “run” mode must reduce total cost of ownership (TCO). Projects on “grow” which improve existing products and services must increase return on investment (ROI). That is to help the business make more money. “Transform” projects which enable new things or even change the game are giving the business a competitive edge. These phases are described in figure 2 which plots also an s-shape curve. ^[6]

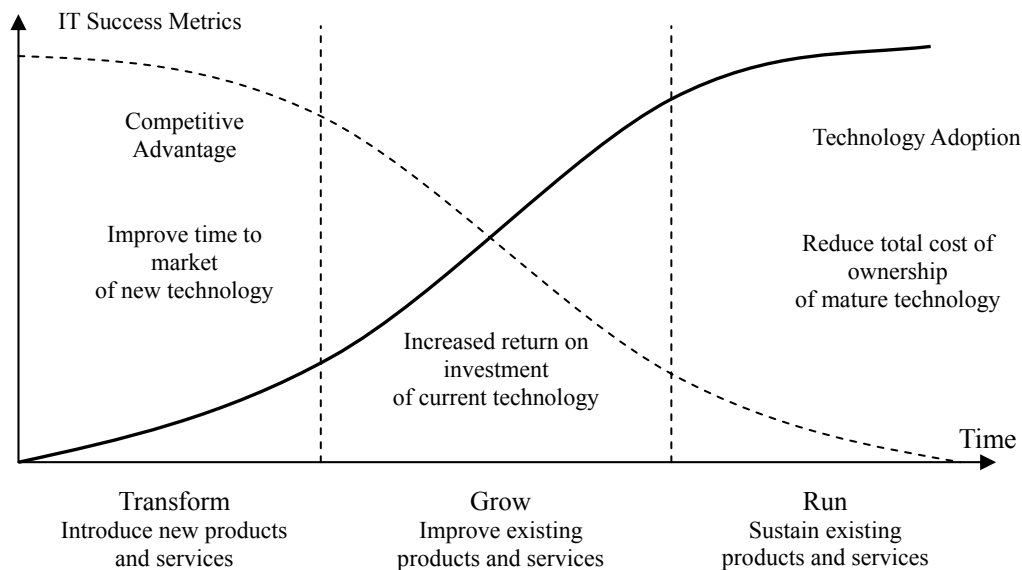

Figure 2 IT Success Metrics ^[6]

Cloud computing can reduce the IT's involvement in "run" projects and offer possibility to shift to "grow" and "transform" projects. This enables IT to move from cost center or provider of services to a value-adding partner for the business. This is considered a big advantage cloud computing can offer. [6]

In addition to requirements for company IT cost efficiency, the cloud services themselves often meet commercial requirements such as: [1]

(1) In general cloud services are reasonably priced. The absolute costs of cloud services are low.

(2) By using cloud services, the company can switch fixed costs into variable costs (or operating costs). The agreements with the cloud service providers are time limited and the company will not have any upcoming costs beyond the agreement term. Services, such as cloud services, are not usually depreciated. In addition, additional capacity can be easily acquired without any set up fees.

(3) Cloud services enable the company to reduce the costs with its own efforts. The invoicing gets lower if the usage is lower, e.g. on monthly basis.

Another cost reduction or cost avoidance comes from maintenance perspective: the company does not need to worry about hardware maintenance or upgrades of the firmware or software but they are rather included e.g. in the monthly fee. If the IT environment is managed by the company itself, the environments get outdated and require bug fixes, upgrades, and configurations and related testing regularly. Finally the hardware and also software gets obsolete due to operating system upgrades or because of elapsing maintenance from hardware or software supplier. This forces the company to make new upfront investments to the IT systems which are often crucial to the businesses.

5 Opportunities

Cloud computing brings great opportunities in relation to cost reduction of ongoing running costs and enables quick application and service deployment. Utilizing common computing platform is environmentally friendly but brings a business challenges to companies who traditionally have collected their revenues from server sales and from technology licensing. This applies to companies such as HP, Oracle (Sun Microsystems) and IBM. Oracle, in turn is having Big Data concept which stores and manage big amounts of data in dedicated servers effectively. Traditional IT vendors have also shift their focus on the cloud's application layer by providing SaaS services to customers who traditionally have purchased standalone database or application licenses. Utilizing similar services as SaaS will ease the learning curve and fasten the technology diffusion. The end user does not recognize any change if the performance and other technical requirements are properly fulfilled.

Cloud based services can also act as an infrastructure to various services for mobile devices. Web surfing has expanded to emails, Facebook and Twitter. All of those are cloud applications. [1]

In emerging markets lots of people would need to access ATMs and other online services. Cloud computing is a tool to enable that with inexpensive investments. As economies grow, more IT based solutions come desirable. The cloud can serve small and midsize businesses that cannot afford building massive data centers. [6]

New growth theory refers to recent modeling of economic growth which explains the rate of sustained growth of per capita income in the long run. The growth process has been affected by three dynamic forces. Firstly, technology and innovations are seen as the engine of sustained growth. Profit-seeking entrepreneurs who forward-look the state of the world make direct and intentional investments that foster technological progress. Second important factor is the dynamic externalities due to international diffusion of knowledge base and the rapid development of information technology. Knowledge spillover effect may be the most significant factor explaining the great differences in marginal productivity of capital between a less developed and a fast or developed economy when taking into account the human capital. Thirdly, trade openness and its impact on sectorial growth of output are crucial for the growth. It has been emphasized that the diffusion of spillover research technology implies the strong connection that is foreseeable between rapid productivity growth and trade or openness. [4]

Cloud services is one element is the broad range of information technology but an important enabler in respect to providing computing capacity and easy application deployments globally. Even if security is foreseen one weakness of cloud computing, an existing cloud instance would have security provisions readily available which reduces the vulnerability of a service.

6 Challenges

Cloud computing brings various challenges for the system and application developers, system administrators and service providers. Virtualization brings challenges for maintenance operations as

multiple virtual machines need to be managed effectively so that the service level can be kept on an adequate level.^[7]

Security, privacy and trust are major concerns when considering and using clouds. Important data and critical operations may be subject to cloud hosting. Hence trust to cloud providers is crucial. In addition, legal and regulatory issues need to be taken into account. Applications and data can reside anywhere in the world. Physical location of data centers and clusters determines the set of laws that are applicable in relation to data management. Some cryptography techniques may not be allowed in certain countries. Banks and insurance companies need to put extra effort to protect the confidential data of their customers.^[7]

Security and privacy issues may slow down the deployment of cloud services and therefore slow down the pace of technology diffusion.

Compatibility may also slow down the deployment of cloud services. Applications that are desirable for SaaS are such that are similar in various companies. For example managing sales funnel is done similarly in many companies and is potential candidate to be used as SaaS. Applications for supply chain management differ from company to company and therefore are not so suitable for SaaS. Similarly the applications for human resource management are fragmented and as such are not the first candidates for SaaS.^[1]

7 Conclusions

Technology diffusion of cloud services have started reasonably quickly. Dotcom burst in early 2000 intensified the use of computing power effectively. Cloud computing cannot be said yet to be domain design but it is gradually reaching that status. Cloud vendors are experiencing growth rate of 90 % per annum.^[8] Especially new services are vastly build on top of cloud computing. The global recession has intensified the efficiency needs in relation to IT projects, to productivity and in relation to the running costs. New innovations in IT are required in order for the businesses to maintain their competitiveness. Cloud computing enables the expansion of IT operations to emerging markets, hence lowering the labor costs. On the other hand geographic expansion enables growth in new geographical areas. Environmental issues certainly speak on behalf of cloud computing as there is need for less hardware appliances.

Data security and privacy issues have been discussed widely in public during the last few months. The importance of them is not diminishing but rather growing as normal citizens start to be more aware of potential underlying threats in respect to their personal and private data. Cloud computing companies and those who utilize cloud computing must address these concerns with great carefulness. Privacy issues are subject to up to privacy legislation which again is moving slowly due to national bodies and is governed by national and international legislations.

Still a sign of the importance of cloud computing is from 2008: when big real estate financiers Fannie Mae and Freddie Mac were withdrawn from the Standard and Poors 500 stock index in September, the other was replaced by Salesforce.com which is a successful CRM supplier fully relying on cloud computing. Salesforce.com has become a core holding item of many technology focused stock funds.^[1]

A Study of Concept Structure of PMBOK Based on Graph Theory*

Naoki Ohshima

Malaysia-Japan International Institute of Technology, Universiti Teknologi Malaysia
Jalan Semarak 54100, Kuala Lumpur, Malaysia
(E-Mail: naoki.osm@ic.utm.my)

Abstract: One especial characteristic of the PMBOK fourth edition is that the data flow between processes is defined with the definition of individual processes. Based on relations of input and the output during an adjacent management process, we can visualize the network structure of 42 project management processes analytically.

The author showed that we could estimate the density of the process flow from the network structure based on the relations during the process of the first proximity.

However, this network structure based on relations of first proximity is not including the indirect relationship among management processes. Therefore, it is necessary to extract a cross-sectional data flowchart on knowledge areas by expanding analysis range of the management pass in consideration of a highly advanced proximity element (process).

Based on this cross-sectional data flowchart, it is able to visualize a complicated management processing flow. As a result, it is found that there were complementary relations between the flow by way and by no way of the project integration management knowledge area. This suggests that network analysis technique is effective as method to visualize the flow of the management process of project.

In this paper, I would like to report the example of visualization of the management processing flow of some project management knowledge areas.

Key Words: PMBOK; Project Management Process; Graph Theory; Network Analysis

1 Introduction

One characteristic of PMBOK [1] is that data flowcharts corresponding to the each management process are described. This data flow chart of the each process is renovated in PMBOK 5th edition [1]. The data flowchart corresponding to the five process groups (a setup, a plan, practice, monitoring and control and end) was macroscopically described before the second edition [2]. In the third edition [3], it was changed to the data flowchart for every the project management (PM) knowledge area and it came to easy to look the flow of the management in each knowledge area.

There are two characteristics of the data flowchart. One is what is described by a viewpoint of the delivery of input and the output of the process concerned. The second is that the mutual relations between process of the knowledge area and process of the outside of the knowledge area are described. This characteristic was succeeded to in the PMBOK fifth edition, and brushing up was planned more.

In the previous paper, it has reported that it is able to visualize the flow of the PM process so far by describing the data flow between all processes based on the graph theory [5].

In this study, I visualize a management process of the PMBOK fifth edition and consider the positioning of the project stakeholder management knowledge area added newly.

2 Visualization of the Management Process

We can visualize the implicit structure such as an organization or the procedure by graph theory explicitly. Network graph is one of visual view graphs by graph theory, and formed only with nodes and lines. The node of the network corresponds an active point of action (e.g., the people in the organization) that information or an object goes by way of. If or action is connected with a node between nodes, I draw a line. I call a diagram provided in this way a network graph. When action is accepted between a node and nodes, it is able to link the node to the node in a line. A diagram provided in this way is called as a network graph. It is possible to express various structures by thus network methodology.

In this research, the node shows the management process of PMBOK, and the link shows the relationship between management processes. Adjacency matrix describes the relationship among the nodes which forms network. The component will be '1' when there is relationship between two nodes, or '0' when there is no relationship. An undirected graph is a graph describing the network in which the nodes are connected by undirected arcs.

* This work was supported by JSPS Grants-in-Aid for Scientific Research No.24501190.

2.1 Management process of the PMBOK 4th edition

From the data flowchart of 42 processes, it is able to get the adjacent line corresponding to the mutual relations between management processes described in PMBOK. It could be visualized the concept structure of the management process of PMBOK by analyzing this adjacent matrix.

In the data flowchart in the PMBOK 4th edition, “*a project document*”, “*the environmental factor of the body*”, “*the process assets of the organization*”, and “*the process assets of the organization*” are treated in almost all processes. For the network analysis, a number and the mutual relations of the node to describe structure become important. Therefore I compare the concept structure when the above-mentioned external elements are considered as a node of the networks with the concept structure based on only 42 processes.

The adjacent matrix demanded from 42 data charts is shown in Figure 1. And a viewgraph of network obtained from the adjacent matrix is shown in figure 2. The viewgraph of network is displayed in the circle mode which placed a node on the circumference. The link between nodes corresponds to the element “1” of the adjacent matrix.

Figure 1

(a) Adjacency matrix for mutual relations among 42 processes of PMBOK4th edition

(b) Adjacency matrix for 42 processes and “*Project documents*”, “*Enterprise environmental factors*”, and “*Organizational process assets*”

Figure 2

(a) Network graph provided from the adjacent matrix shown in figure 1(a)

(b) Network graph provided from the adjacent matrix shown in figure 1(b)

Figure 2(a) is network graph which described from the adjacent matrix by the 42 process without external elements. This network graph is corresponding to the data flow only for the knowledge area. Figure 2(b) is a network graph when I considered “*a project document*”, “*the environmental factor of the body*” and “*the process assets of the organization*” as a node.

2.2 Management process of the PMBOK fifth edition

Figure 3 is the adjacent matrix based on the data flowchart of the PMBOK 5th edition. In the data flowchart of the PMBOK fifth edition, “Sponsor”, a “Customer”, and “Sellers” were added as new elements of external to processes.

Figure 3

- (a) Adjacency matrix for mutual relations among 47 processes of PMBOK 5th edition
- (b) Adjacency matrix for 47 processes and “*Project documents*”, “*Enterprise environmental factors*”, “*Organizational process assets*”, “*Sponsor*”, and “*Customer*”, “*Sellers*”

Figure 4

- (a) Network graph provided from the adjacent matrix shown in figure 3(a)
- (b) Network graph provided from the adjacent matrix shown in figure 3(b)

Figure 4(a) is network graph of 47 processes without external elements. Figure 4(b) is the network graph (expanded network) corresponding to the matrix including “*a project document*”, “*the environmental factor*”, “*the process assets of the organization*”, “*a sponsor*”, “*a customer*” and “*a seller*” in addition to 47 processes.

3 Data Flow Diagram for Stakeholder Management

The most important characteristic feature of the PMBOK 5th edition is that a stakeholder management knowledge area was added. The management processes for stakeholders were incorporated in the communication management knowledge area in the PMBOK 4th edition. The PMBOK 5th edition isolated these and described those as independent chapters.

The above-mentioned Small world network indication is insufficient while it is able to realize visualization of the concept structure of PMBOK to describe the management flow in the individual knowledge area. Therefore, the data flow diagram of the stakeholder management knowledge area is described in order to estimate the range where the stakeholder management had an influence on the management process. The data flow diagram for communication management knowledge area of PMBOK 4th edition is shown in figure 5. The data flow diagrams of the communication and

stakeholders management knowledge areas of the PMBOK 5th edition are shown in figure 6 and 7.

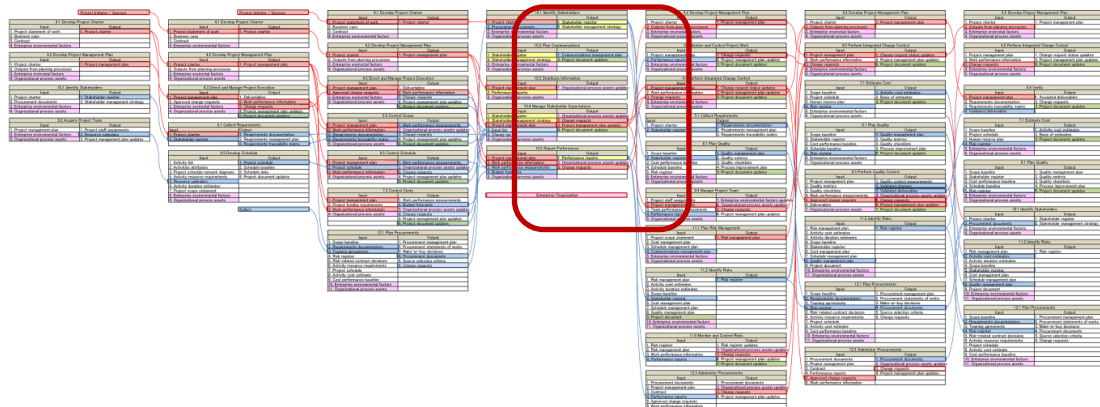

Figure 5 Detail data flow diagram of Communication Management Area of PMBOK 4th considered until the third proximity. Square is indicating the set of inputs & outputs of Communication Management processes in PMBOK 4th.

Figure 6 Detail data flow diagram of Communication Management Area of PMBOK 5th considered until the third proximity. Square is indicating the set of inputs & outputs of Communication Management processes in PMBOK 5th.

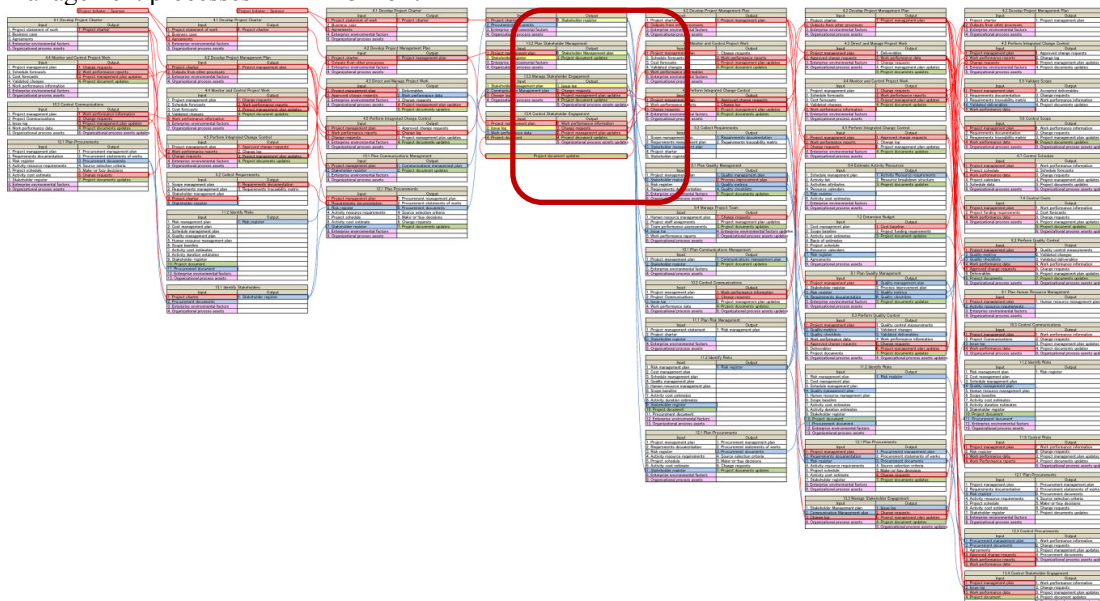

Figure 7 Detail data flow diagram of Stakeholder Management Area of PMBOK 5th considered until the third proximity. Square is indicating the set of inputs & outputs of Stakeholder Management

processes in PMBOK 5th.

4 Discussion

It is observed that network density of the expanded network graph which is including “*a project document*”, “*the environmental factor*” and “*the process assets of the organization*” shown in figure 2 (b) increases in comparison with figure 2(a). This means that three elements of “*a project document*”, “*the environmental factor*” and “*the process assets of the organization*” make the relations of 42 management processes stronger. In the comparison between figure 4(a) and figure 4(b), it is found a similar relation. Furthermore, it is considered that the density of the network graph of PMBOK 5th becomes higher rather than the one of PMBOK 4th edition.

The above-mentioned results indicate that, the network density of the PMBOK 5th edition becomes minute according to adding “*Sponsor*”, “*Customer*” and “*Sellers*” as new outside factor of the process and improvement of the management network by creation of project stakeholder management knowledge area as a new chapter.

5 Conclusion

Based on flow chart of the PMBOK fourth edition and the fifth edition, I visualized the concept structural analysis of each management process. As a result, I showed that the network structure of the process became minutes by supporting external elements having increased and a stakeholder management knowledge area having been established in the PMBOK fifth edition.

Abstract: Numerous events have taken place during recent years, of which many have had a huge impact on the way of doing business. Some of these events have even caused an economic crisis in world. This caused an un-certain and challenging business environment and has battered many managements that are running businesses all over the world. This paper supports the view that dynamic capabilities can be used successfully in a fast changing business environment for improving firm's efficiency.

This research is constructive approach including also several interviews and case studies. Key findings of the study are the elements of key success factors: entrepreneurship strategy, R&D performance, operational excellence and innovativeness. This research is focused on to power electronics business field which is study's limitation. This research helps directors and managers to think more widely and make better decision for success of the company. This research results bring additional value of the previous studies regarding dynamic capabilities and flexible business concepts.

Key words: Dynamic Capabilities; Entrepreneurship Strategy; Operational Excellence; Innovation; Agility.

1 Introduction

Due to tightening competition, firms need to be more agile and resilient in their business sector. The need of this agility is to make them more fit for the prevailing competition for the market. The competition requires firms that are agile, and resilient. However, this resilience should be in line with their resources, capabilities, and readiness of the firm; they should reconsider and reconfigure their dynamic capabilities. This reconsideration and reconfiguration should also be agile and resilient in order to cope up with the dynamic market.

In addition, the preparation for this process requires competent management and leadership. The management and leadership are responsible for guiding, planning, controlling and monitoring the whole process. It needs to be able to sense and respond to the market it targets and the market as a whole. It should also be innovative, as well as empower its subordinate to be creative and encourages them to make new innovative proposals. This should be done in a flexible but agile manner. The decision-making in the organization should be decentralized to speed up the implementation of the new ideas.

Furthermore, this management and leadership should be transformational in order to create an interaction between leaders and their subordinates^[1].

Conversely, Garvin argues that, a learning organization gets more skilled at creating, acquiring, and transferring knowledge which in turn helps it to adapt to new knowledge, interaction behaviour and insights^[2]. This interaction and communication allows for peer learning, teamwork building, collaboration, and creative thinking. This creativeness becomes innovative knowledge and technology that helps in problem solving; i.e. overall performance of the organization^[3]. There is also evidence that, training and development has been associated with increasing market share and growth^[4]. Such knowledge could be extended further to global operations or large-scale operations.

The study in this paper suggests a model that can be used by organisations to be successful in a turbulent market environment. This model combines the theory of science and methodology. The models' methods and its paradigm have an influence on the research problem and it is implemented in this research. The contribution achieved from the research, could suggest that, organisational management should have a competent entrepreneurial strategy that is unique.

2 Thoretical Dramework and Research Design

The model theory comprises of different literature from numerous authors. One of the key literature theories comes from Robert^[5]. Although this model could be implemented in firms, the results from the case study should not be generalized, but to expand and generalize other theories. However the design of

the case study covers units of analysis, suggestion logic linking data to the propositions, criteria for interpreting the findings and answering the three study questions;

Qn1. How is strategy architecture developing?

Qn2. How to implement necessary changes in dynamic capabilities?

Qn3. What are the key success factors for high technology (power) electronics companies with global operations?

The model is designed to meet the construct validity, internal validity, external validity, and reliability checks due to the reliability of the informants that were used for collecting data.

The model uses a constructive research approach, which is normally used in the discovery process, where, there are many possibilities that are still open, in the sense of ontological choices. The model extends on the already existing knowledge to piece and fix the possibly missing links.

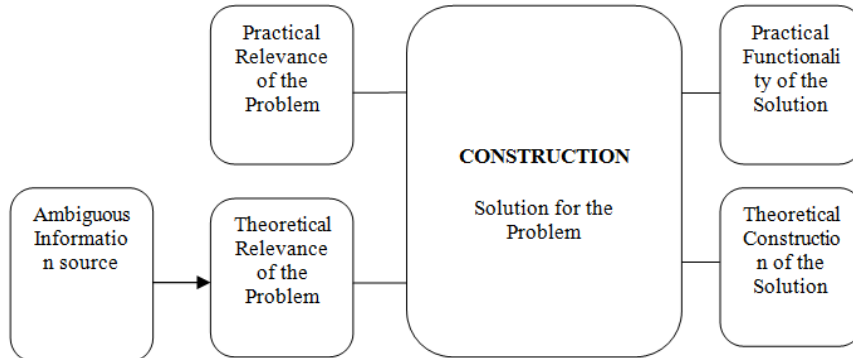

Figure 1 Model Theoretical Diagram Adapted from Constructive Research Approach in Business Science

The central research question of this paper is as follows: Can you create enterprise architecture framework for the firms which have global business and are operating in a turbulence business environment to handle dynamic capabilities and agility in an effective way. The main question has been divided to the three sub questions by using ontology terminology:

(1) What are the main classes (and subclasses elements) that a company should take into account to be successful in a turbulence global business environment?

(2) What are the most important slots?

(3) What are the slots that are most important?

2.1 Literature review

2.1.1 The theoretical construction of the model

The theoretical construction of the model is based on the concepts of dynamic capabilities (flexibility and responsiveness) to achieve agility in an organization in order to improve organization performance [6].

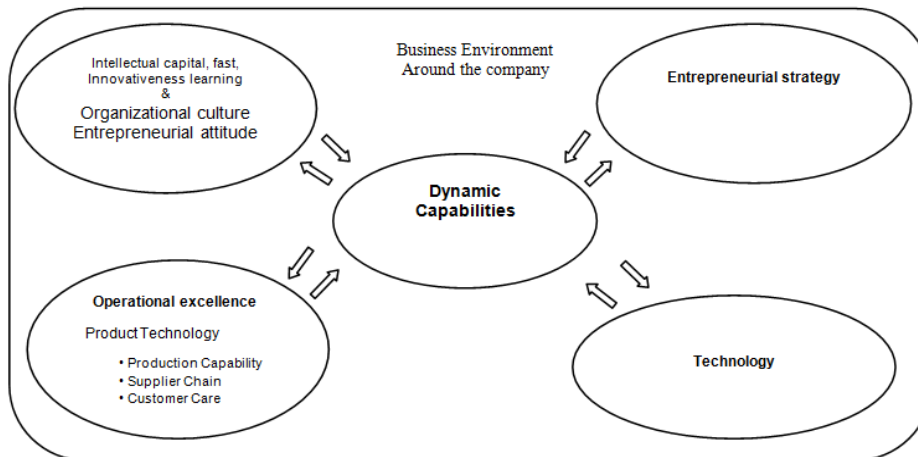

Figure 2 Theoretical Construction of the Model

The figure above (Fig 2) illustrates the flexibility and responsiveness of the model that is used in

the research. The theoretical construction is supported by dynamic capability framework that is also comprises of three major elements: organizational structure, organizational performance, and competitive intensity^[7]. Despite the fact that organizational and firm performance is influenced by strategy structure performance, only little empirical research has been conducted to link it to the firm's dynamic capabilities.

2.1.2 Entrepreneurial strategy

In entrepreneurial strategy, there should not be a gap between business management and technology but they should rather be intertwined^[8]. The two business and technology strategies are viewpoints dualistic viewpoints to a mutual strategy. Strategy, in a business, organizes the firms' resources to position its self to win and no two-organizations' thought of strategising the same way. This has its root from many angle of the firms' processes, strategy, resource and positioning; just to mention a few.

It should be noted that the creation and implementation strategic management of technology has its challenges. It is ideal to for firms to think while linking business and technology developments as a common strategic discussion. Hakkarainen & Talonen suggested that strategic thinking should be in three levels; Strategic Level for strategic positioning and generation (developments), Tactical Level for continuous planning and adaptation (short-term) and Operational Level for Implementation (long-term). They also observed that at strategic challenges required a better understanding of the internal and external business environment changes analyse potential and then consequently make decision on strategic business options for the future^[9].

2.1.3 Innovation

There is an impact of innovation on innovation process and product innovation. Technological change in many cases triggers innovation which in turn acts as a driver in firms' competition as well as economic process development. Management need to be concerned about how far institutions and organisational forms promote innovations due to its' influence in industrial organisation, market and supply chain, economic policy. Furthermore, in many cases, innovation is used by many companies as a competitive strategy as well as market leadership. Although this is the case it should be noted that, many firms that engage in such strategy should be will prepared technologically as well as financial; Resource and Knowledge based View (R/KBV). Overlooking this fact has led many firms to bankruptcy.

2.1.4 Decentralized decision making organization model

In today's competition and un-certain markets, globalisation has been on an increase for many organisations. These decentralised units can be seen as "teams" of the organisations, and need to be standardised with complete competitive advantages and access to competencies most especially in Research and Development (R&D). However, these come with challenges such as collaboration, integration, and networking, to mention a few, that require a dynamic strategic management that is efficient and will supervision these strategies^[10]. All this supervision requires effective decision making in these distributed project teams. Bourgault, & Nathalie suggested that dynamic strategic management approach is how firms us their planning technique to reach their goals, as variables' change with time. In addition, it should be a growing planning process, flexible internal and external factors, manageable and sharable in order to show individuals their targets^[11].

A study made by Rubenstein on the problem of decision-making, in phases like analysis and statement of alternatives, best choice from the alternatives, communication and implementation of the decision as well as checking to see whether the decision was implemented as intended^[12]. Rubenstein observed that, in a role of top management or supervision, there should be a clear idea of the objectives for which the company supports its R&D.^[12] Conversely, in an intensive empirical study using a quantitative approach study made by Bourgault, & Nathalie, on decision-making processes in New Product Development (NPD) linked to team autonomy, revealed that, formal decision-making process is even more important for distributed teams that are highly dispersed. In addition, autonomy is very important for the success of dispersed teams while formalization will add value to teamwork, most especially when team distribution is on the increase. This may see less formal decision-making process and teams may use it as a strategy, however, the top management should retain central role on the decision of how far should dispersed team be empowered.

2.1.5 Effective processes

How should industries new product manager take to improve new product performance? In the past decades, a lot of research into reasons for new product success and failure has contributed to effective new product management. It is crucial to acknowledge technical opportunity, market, proficient internal R&D management, decision-making process, and logistics^[13]. In addition it is also important to have

modularity in an effective process ^[14]. This is advantageous in today's competition as a strategy to improve on the lead time. In addition this is also used to catch up with the growing diversity of the market demand in variety of products.

2.1.6 R&D performance

The ideology of performance in new product and innovation was also theorised as capitalist economic evolution; process of the innovative renewal of business routines. In addition, the development of economics requires coordinated efforts within the "fundamental fields" of theory, history, statistics, and economic sociology ^[15]. Although Research and Development (R&D) projects are necessary for outstanding corporate performance it still remains a big risk. Some studies revealed that many new products remain stable at less than 55%. Although this is the case, the past decades have revealed that for instance, in the 70s' and 80s', new products accounted for 20 % and 33 % of corporate profits respectively ^[16]: 139, and the number is still at the increase today; since this is the focus for many firms, the cost is also increasing.

An intensive study made by Keller, revealed better performance in, technical quality, and better budget of cross-functional teams in research and new product ^[17]. However, there is still need for individual effort in the teams. In addition, Trent made a study on managers on how global leadership teams are coping with these challenges of essential qualities revealed that, teams should also be agile in their thinking and who to involve in the decision-making processes, flexible and have a charter and operating principles ^[18]. This save a lot of time and that may be caused by bureaucracy and un-necessary waiting or confirmation from the superior authority, yet some times, the market makes the decisions. Berman argued that, a firms' strategy process, that involves market with technological knowhow, would bare fruits in a number of innovative sectors. When responding to market changes, firms may find themselves setting the pace of innovation in their industries, consequently leading the competition ^[19]. For that matter, firms should value their customers a part of the brain power that drives innovation and performance.

Conversely, the model in this study is related to performance and Total Quality Management (TQM). Total Quality Management has been considered as a management tool for many businesses to keep the competitive advantage ^[20]. There are some earlier studies that argued that quality could be a strategic advantage core variable for firms in competition. A study made on improving Product Development (PD) performance using concurrent engineering (CE) suggested that, CE has diverse views and applications in and has potential to improve the performance on innovation and New Product Development ^[21]. The study examine further how responsible is Total Quality Management in increasing the performance of firms.

3 Results

3.1 Key success words in next five years period

Below (Fig 3) is the graph of the answers to the question; what are key success word in next five years period?

Figure 3 Key Success Words

The X-axis lists all the categories which are mentioned most often. The Y-axis shows the number of answers in the each category. On the graph we can see that all of the interviewee said that in the future most important issues are the reaction fastness to the changes around the company as well as

management and leadership skills. Especially for high tech companies where technology develops rapidly, it is lifeline for the companies to be fastness and agility.

Figure 4 Ideal Company Profiles

3.2 General indicators of factors affecting success in the case study

Dynamic capabilities in high technology power electronics field based on the analyzes and interviews that were made can we summarized following key success factors or classes under the dynamic capabilities to be most important factors in high technology power electronics field:

- ✧ Strategy
- ✧ R&D Performance
- ✧ Operational excellence
- ✧ Intellectual capital

4 Conclusion

It seems that firm's size as well as globalization level effects to the importance level of classes defined above. We can summarize that international operated companies need wilder competence and knowledge platform than local companies. Entrepreneurial strategy, effective processes, innovativeness and dynamic capabilities which take environment changes to the account are one way to develop a more agile customer oriented company^[22] and^[23] in order to avoid failure^[24]. Working in collaboration with customer and partners, it is possible to understand customer needs more deeply and to achieve more faster, flexible, and more agile processes to support the changing customer needs^[25]. The aim of this study was to understand and to analyze factors that are most important to the customers in a power electronic business industry. One of the key findings was the importance of effective information flow in a global business. This is related to the communication of technical, delivery, installations and service matters.

The Current Situation and Strategy Choice of Technology Sourcing Foreign Direct Investment in the U.S. by Chinese Enterprises*

Huang Ying

School of Economics and Management, Wuchang Branch of Huazhong University of Science and Technology, Wuhan, P.R.China, 430064
(E-mail: grace.00123@aliyun.com)

Abstract: The paper uses qualitative analysis method to describe current situation of technology sourcing foreign direct investment (TSFDI) by Chinese enterprises in the United States from viewpoints of investment motive, principal investors, investment industry, investment destination and entry mode, showing a good development but still lag behind. In order to enhance overseas technology sourcing effect, the paper concludes effective strategies less discussed in existing studies. Chinese government should promote private enterprises to join TSFDI and encourage the service sector to participate in FDI, especially to seek knowledge in high-end services in the US. Besides, Chinese enterprises should strengthen their regional layout in technology centers and industry clusters in the US, and comprehensively utilize a variety of entry modes.

Key words: Chinese enterprises; Technology sourcing foreign direct investment; Technology innovation

1 Introduction

In early 20th century, global economy has entered into an era mainly driven by knowledge and technology. There is no firm of any country in international economic competition not to build its competitiveness on technology and capability. Recently, technology sourcing foreign direct investment(TSFDI) has become an important channel of international technology diffusion and an essential mechanism of enhancing technological R&D efficiency for multinational firms.

Technology Sourcing Foreign Direct Investment, namely TSFDI, refers to firms with leading efficiency domestic but lagging behind foreign technical level buy R&D departments of high-tech multinationals abroad, or set up overseas technology development subsidiaries and R&D institutions with sole proprietorship or joint venture, aiming at gaining crucial knowledge such as advanced technology and organizing ability to improve competitiveness effectively.

TSFDI Study started in discussion on FDI's motives and determinants by enterprises from developed countries. Kogut and Chang (1991) investigated Japanese enterprises investing to the U.S. and drew conclusions that access to technology was the motivation of Japanese FDI, and joint venture was an important way. Similar conclusions were drawn by Yamawaki(1993). Neven and Siotis(1993,1996) argued technology was an important driver for American and Japanese FDI, and M&A, joint venture and participation were more likely to be used by TSFDI enterprises to maximize technology spillovers. Branstetter(2001) showed FDI in the US was an important way to acquire knowledge overflow for Japanese enterprises. Cantwell(2004) pointed out American companies investing in British manufacturing was indeed to get technology, with obvious industry difference in technology acquisition effect. Pradhan J. P. and Singh N(2009) found India's auto manufacturing enterprises went abroad through FDI to get technology, market and information.

Study on R&D internationalization also offers evidence that seeking technology may be FDI's motivation. Cantwell, Hodson (1991) and Fors (1998) found setting up R&D institutions abroad was driven by technology acquisition. To gain knowledge from 'center of excellence' in foreign countries was the purpose. Serapio and Dalton (1999) analyzed the U.S. R&D inflows and concluded that foreign parent companies in pharmaceutical, biotechnology and electronics had established or acquired local R&D institutions to obtain technology and improve their global capacity in technological development and innovation. Kuemmerle (1999) pointed out in order to gain more R&D resources, multinationals built their R&D institutions mainly near universities. Based on British manufacturing analysis, Nigel Driffield, James H. Love (2003) proved technology was overflowed from domestic industry to foreign multinationals and the reverse technology spillover confined to relatively intensive R&D industries.

To sum up, TSFDI study starts late and is not systematic. Conclusions based on empirical analysis

* This paper is supported by scientific research fund project(No.2012XK06) of Wuchang Branch of Huazhong University of Science and Technology.

are different and analyzing methods need further improvement. Especially, further research on Chinese TSFDI in a particular host country is less. Thus, the study on Chinese TSFDI in the U.S. is of theoretical significance. Besides, under the background of increasing TSFDI, the discussion on features, problems and strategies of Chinese TSFDI in the United States will enable Chinese firms be clear about the gap between themselves and leading multinationals, and their future development direction: acquiring technology spillovers from host countries to improve international competitiveness.

2 The Current Situation and Characteristics of Chinese TSFDI in the U.S.

Compared with TSFDI in the U.S. by multinational companies from developed countries, Chinese enterprises started to implement TSFDI in the United States late, and lacked experience and technological strength, thus presenting following features in investment motivation, investment subject, investment industry and destination, and entry modes.

2.1 Investment motivation: seeking technological advantage and nurturing domestic R&D

Different from TSFDI motivation (for both technological advantage using and technology learning) in US by multinationals in developed countries, Chinese TSFDI in US is mainly to seek technology advantage. By purchasing strategic assets such as technology, brand and transferring new technology, Chinese enterprises improve transnational operating efficiency especially technology innovation ability, and nurture domestic product R&D. Chinese enterprises attach great importance to the US market. Lixin Cheng, the president of north American of ZTE, believes that the US is the world's most high-end and biggest telecom market and ZTE should take the leading position in American market to become the world's outstanding communication enterprise. Once setting up the brand in US market, for the global is an exemplary role. In addition, innovative ability seeking from US can also regurgitate product R&D in other markets. Therefore, the purpose of Chinese TSFDI in the US is to acquire advanced technology to enhance competitiveness in domestic and international market.

2.2 Diversified investment subjects

Chinese TSFDI in the US is mainly conducted by large and medium-sized enterprises with strong technological strength. Relying on existing economic power, technical ability and policy support, they set up international joint venture and wholly owned enterprises in technology-leading developed countries and developing countries, learning and absorbing advanced technology and high-tech resources. Investment subjects tend to be diversified in recent years. Take Chinese direct investment stock in the U.S. for example, from 2000 to 2012 in the third quarter, a total number of 593 Chinese direct investment took place, with 149 deals by state-owned enterprises, involving the amount of \$12.609 billion, accounting for 55.7%; and 444 deals by private sector, occurrence amount of \$10.016 billion, accounting for 44.3%.¹ Especially in industries of electronic and information, mechanical manufacturing, biomedical, aerospace and vehicle transportation and renewable energy, Chinese direct investment in the U.S. belongs to typical TSFDI. In these sectors, state-owned enterprises' investment value is \$4.607 billion, accounting for 49.7% and private sector's investment amount is \$4.659 billion, accounting for 50.3%. Take Chinese investment flows to the U.S. in these industries for example, state-owned enterprises' investment amount accounted for above 50% in calendar year 2009-2011.² When Chinese firms go abroad supported by government's policy or conduct transnational M&As to acquire strategic assets, they should pay attention to avoid bringing negative images of threatening national security to host country's government. Especially, Chinese state-owned enterprises which get low-cost overseas M&A loans to buy American key technology firms in sensitive industries, are vulnerable to U.S. government's resist. Chinese TSFDI investors tend to be diversified, and listed companies and private enterprises without a close connection with government are more welcomed by the U.S.

2.3 Investment industry: concentrated in high-tech manufacturing and recently involved in advanced services

Chinese TSFDI mainly tend to invest in high-tech manufacturing. Take China's direct investment in the U.S. for example, since 2008, the biggest growth has been in manufacturing, with both acquisitions and greenfield investment, including strategic assets-seeking M&A. From 2000 to 2012 in

¹ Daniel Rosen, Thilo Hanemann. Chinese FDI in the United States: Q3 2012 Update[R]. <http://rhgroup.net/interactive/china-investment-monitor,2012-10-08>

² Daniel Rosen, Thilo Hanemann. An American Open Door? Maximizing the Benefits of Chinese Foreign Direct Investment[R]. http://www.asiasociety.org/files/pdf/AnAmericanOpenDoor_Chinese.pdf, 2011-05-04

the third quarter, according to investment value, most Chinese TSFDI in the U.S. was in industrial machinery, equipment and tools, followed by electronic equipment and parts. And there is a certain correlation among investment industry, investment subject and entry model. From table 1 and table 2, for Chinese FDI to the U.S., in the aviation and automobile transportation industry, state-owned enterprises dominate and opt for M&A; In IT industry, private enterprises dominate and often adopt transnational M&A; In biological medicine, private enterprises dominate and use both greenfield and M&A; In machinery manufacturing, state-owned enterprises dominate and private firms perform actively, mainly adopting greenfield and starting to use M&A; In renewable energy, state-owned and private companies are all involved and pay equal attention to both greenfield and M&A.

Recently, Chinese companies began to seek assets in American advanced services by cross-border M&A. In May 2012, with \$2.6 billion, Dalian Wanda Group Corp Ltd, the largest theater owner in China and Asia, acquired AMC Entertainment, the world's second-largest cinema chain. Wanda's merger with AMC acquired high-quality resources in the whole world, including 346 theaters, a total of 5028 pieces of screens, and became the largest and defining M&A by Chinese private enterprise entering to the cultural industry in the US. In December 2012, China's enterprise group led by Xinhua Trust spent \$5.28 billion to acquire a 90% stake of international aircraft leasing finance company (ILFC), under American international group (AIG), and mastered its customer resources of more than 80 countries and regions in the world, and more than 1000 aircraft and new orders of 239 energy-saving planes.¹ In March 2013, Shenzhen Huada Gene made a \$118 million acquisition of Complete Genomics company in the US, the innovation leader of human's whole genome sequencing. The combination of two companies would create the integration of complementary advantages of both sides in science, technology and R&D, which enabled Complete Genomics to become a more successful global innovators, and also made Huada Gene to obtain complete and accurate technology of human genome sequencing.² China's TSFDI in the U.S. has begun to expand into high-end services and Increasing Chinese services multinationals go abroad, seeking cutting-edge technology to build strong global competitiveness.

acquisition.

2.4 Investment destination: distributed in technological forefront headed by California

Chinese TSFDI mainly targets at developed countries and some developing countries of industrial cutting-edge technology. The U.S. is rich in advanced technology, such as core techniques in computer, aerospace, new materials and etc. Thus, American is a preferred location by Chinese TSFDI. Take Chinese TSFDI stock in the U.S. for example, from 2000 to 2012 in the third quarter, California is an important area for Chinese investors, with a total number of 163 deals and investment amount of \$1.4 billion. Electronic equipment and IT industry are hot in California, with investment amount of \$878 million, 62.7% of which flowing into California for acquiring advanced IT resources (see Table 3). Besides, industries such as renewable energy, biological medicine, machinery manufacturing, aviation and automobile transportation are also targets for Chinese enterprises. California has many obvious advantages. California is the largest market in the U.S. and the portal to the rest of American market; California is the global leader in high-tech and high value-added service. Chinese enterprises are not only weak but also eager to invest in these industries. These unique advantages attract Chinese investors to California.¹ New York ranks second, with the number of 47 deals and a total amount of \$3.2 billion. Electronic equipment and IT industry become the first goal with \$1.94 billion flowing into, followed by renewable energy, biological pharmaceutical industry, etc. Texas ranks third with a total of 46 deals and amount of \$2.7 billion. Besides fossil fuels and chemicals industry (\$1.408 billion), machinery manufacturing is dominant, with investment amount of \$1.132 billion, followed by electronic equipment and IT, renewable energy industry. Illinois is the fourth with a total of 40 deals and the amount of \$2 billion. Machinery manufacture ranks the first place for \$1.537 billion, then for renewable energy (\$278 million), electronic equipment and IT industry (\$105 million). Michigan ranks fifth with 34 deals and \$958 million. Air and automobile transport with \$912 million is in the first place. Thus, industries such as electronic equipment and IT, high-tech machinery, renewable energy, biological, pharmaceutical, aerospace and vehicles transportation have become investing targets for Chinese TSFDI. California, New York, Texas, Illinois and Michigan, based on their respective advantages, build technological innovation forefront in different industries and become Chinese TSFDI's target destinations.

Machinery Manufacturing	24	0	1132	1537	31
Renewable Energy	114	103	41	278	0

Source: <http://www.rhgroup.net/interactive/china-investment-monitor>

2.5 Entry mode: adopting transnational technology sourcing M&A to obtain creative assets

Chinese multinationals are increasingly using transnational technology sourcing M&A in the US, in order to quickly absorb and master important creative assets of target enterprises, and regurgitate domestic technique defects. Take Chinese FDI in the U.S. for example, from 2000 to 2012 in the third quarter, a total number of 593 cases of Chinese FDI took place, with 389 cases of greenfield investment(\$3.575 billion), and 204 cases of acquisitions(\$19.05 billion). In 2010, there were 25 greenfield projects and 34 acquisitions and the number of transnational M&A started more than greenfield. The investment amount of M&A is much higher than greenfield overall. When it concerns host country's economic security, entry mode is closely related to many factors such as industry, specific technology and investment subject. Take Chinese FDI in the U.S. for example, in politically sensitive sectors such as aerospace, oil, communications and etc, if Chinese firms use cross-border M&A, they will be restricted to buy below the holding level. In insensitive industries, Chinese firms are increasingly buying assets rather than equity, and private enterprises and listed companies are more popular. Recent Chinese FDI in the U.S. Shows that the proportion of greenfield investment is higher than the average in

¹ Daniel Rosen, Thilo Hanemann. Chinese Direct Investment in California[R]. <http://www.asiasociety.org/centers/northern-california>, 2012-10-30

other countries before 2010. The greenfield investment is mostly conducted by Chinese owned companies in communications equipment, renewable energy, biotechnology, aerospace, engine and pharmaceutical.

3 The Strategy Choice of Chinese TSFDI in the U.S.

Dominated by multinationals in developed countries in fields of technology innovation and TSFDI, strategy choice should be made by Chinese TSFDI enterprises to promote technology acquisition effect.

3.1 Multiple support for private enterprises in TSFDI

As for multinationals in developed countries, both large-scale group and small and medium innovative enterprises are important subjects to promote TSFDI development. Thus, a strong enterprise team of flexible mechanism and diversified subjects is needed in Chinese TSFDI. In July 2012, the national development and reform commission (NDRC) announced the 12th five year plan about guiding principles of China's inward and outward FDI development. In terms of Chinese outward FDI, investment decision-making quality and private sector investment promotion are both emphasized. Thus, under the guidelines, small and medium-sized enterprises should be encouraged to participate TSFDI supported by policy guidance and financial backing. Especially involving in M&A in politically sensitive industries of developed countries, Chinese private companies tend to avoid the negative image of threatening national security and the boycott of developed countries' governments, to successfully obtain key technology.

3.2 Strengthening TSFDI layout in high value-added service

In terms of TSFDI by enterprises in developing country, Indian firms conduct TSFDI in high-end service industry gathered with intangible assets, to achieve strategic breakthrough quickly. In high-end service industry, most Indian investment focuses on industries of information services and software services. The seven biggest Indian multinationals in service sector are engaged in services of processing data, software and computer programs. India's technology sourcing M&A often occurs in the service industry of telecommunications software, and M&A object is mainly American and British companies. Thus, Chinese enterprises should strengthen TSFDI in high value-added services on the basis of consolidating TSFDI in high-tech manufacturing in order to improve investment efficiency and to maximize overseas technology acquisition effect.

In July 2012, NDRC published the 12th five year plan, which listed advanced manufacturing, energy, mining and agriculture as priority and encouraged firms to conduct FDI in high-tech manufacturing, R&D and advanced services. This suggests that the Chinese government is actively encouraging and guiding service multinationals to invest abroad, and also provides institutional guarantee for Chinese enterprises to promote TSFDI in the US.

3.3 Maximizing spillover effect in industrial clusters of leading technology

Chinese TSFDI in the U.S. mainly concentrated in California, New York, Texas, Michigan and Illinois. California and New York are clusters of advanced IT enterprises. Texas enjoys developed manufacturing, with Illinois preferring developed machinery industry and Michigan possessing developed auto transportation. Based on their advantages, these states build technological innovation forefront in different industries. At the same time, industrial clusters are concentrated with resources and technology in whole value chain, such as strict buyers, specialized suppliers, human resources, financial institutions and well-developed supporting organizations. Enterprises in the cluster are likely to acquire talents, information and new technology, to be more capable of innovation. Therefore, on the basis of original geographical distribution, Chinese enterprises should strengthen strategic layout of industrial clusters of leading technology in the US.

3.4 A Comprehensive and flexible use of diversified entry modes

Experience of TSFDI by leading multinationals shows that a comprehensive and flexible use of various entry modes such as setting up overseas R&D institutions, establishing international technology alliance and conducting transnational M&A is the best choice. In recent years, Chinese companies are increasingly using transnational technology sourcing M&A in the US, in order to quickly acquire creative assets. However, recent events indicate that Chinese M&As towards key technology industries and enterprises often suffered block from the U.S. Congress. In order to invest smoothly, China's enterprises should fully understand characteristics of technology, enterprise and environment, use various entry modes of establishing overseas R&D institutions, international technology alliance and transnational M&A comprehensively and flexibly.

4 Conclusion

Chinese TSFDI in the US, a global technology-leading nation, just get started, showing a good development in investment motives, principal investors, investment industry, investment destination and entry mode. However, because of late start, lack of experience and technical strength, Chinese TSFDI has obvious gap with advanced multinationals. To promote overseas technology sourcing effect and regurgitate domestic enterprises and industries effectively, under the guidance of national FDI principle, Chinese enterprises should actively and flexibly select the strategy: private enterprises of strong international competitiveness should join TSFDI; technology acquisition in high-tech manufacturing should be consolidated and technological layout of high value-added services should be strengthened; the regional layout of technology hub and industrial clusters in America should be strengthened; various entry modes should be comprehensively utilized.

TSFDI by enterprises in developing countries is a relatively new research subject, involved in international economics, development economics, management economics and other fields. In future, China's country-specific and industry-specific TSFDI will become one research direction. Besides, the in-depth exploration and empirical analysis on micro mechanism of technology upgrade and independent innovation through TSFDI will be another exploring direction.

A Study on Credibility in Product Market and Its Influence on the Market Transaction

Jin Qin, Zhang Huaimin

School of Marxism, Wuhan University of Technology, Wuhan, P.R.China,430070

(E-mail: jean0523@163.com)

Abstract: Credibility is the important behavior code which must comply in modern business conduct, but also an essential means to ensure fair market order. This article analysis merchandise transactions credibility between businesses and consumers, discusses the game process of credibility to build. The study showed that: when the institutional environment constraints of the market environment is effective, companies have an incentive to choose trustworthy, trade fairs occurs, consumers will receive a larger utility, enterprises have larger income; The key of market credibility to build is institutional environment.

Key Words: Credibility; Product market; Market transactions

1 Introduction

In the commodity trading market, credibility is a commitment made by the enterprises to consumer that the information of product quality, performance and so is true, this commitment usually does not have the legal enforceability. So, why make a commitment, why consumers believe this commitment?

In reality commodity trading market, the product information between enterprises and consumers is asymmetric, usually the understanding level of enterprises about its products is far beyond the understanding level of consumers such as cosmetics, Enterprises fully understand how much effect, but consumers do not understand. Consumers based on what to buy them? The first way is to collect all market and product information, to be fully understood before deciding to buy; the second approach is based on advertising and other readily available information and enterprises' commitment to deciding to buy. The first way, the information collection cost is too high; often more than the value of the consumers buy goods, this way consumers are not commonly applied. The second approach is dependent on the information of enterprises disclosure and believes in its authenticity.

To ensure that the interests of consumers are not compromised, manufacturers must be committed to its authenticity of the information disclosed, is the credibility of the enterprise. Credibility is a signal, indicating that the information is true. For enterprises, if not trustworthy, does not fulfill its commitments, it is necessary to lose consumers' money votes, in this sense, credibility enable enterprises to have to pay the price of telling lies, fraud, a enterprises' credibility is higher means the cost of tell lies, deceive is greater, and thus the more trust of consumers you can get.

2 Basic Concepts of Game Theory

Game theory studies are the theory of respective decision-making optimization among two or more than two interest groups through interaction. It with general decision-making optimization theory is different: it's interests, game theory involved in the conflict among the parties; party to implement the optimization of their decision, in order to maximize their individual interests; the interaction between people and other decision-makers in decision-making, it is a personal decision will affect another person, a person's decision will affect other people; in game theory, think that the participants are rational, that is to say the party has the ability to engage in logical thinking of rational level.

The concept of game theory contains rich content, the main action, participants, strategy, payment, information, results. In the various elements, the description of a game, must include three elements of participants, strategy and payment, these factors of operations and information are to increase the content. Action, participants and the consequences all become the "rules of the game". The game analysis, mainly in order to make the rules of the game is balanced.

The participants: in a game, the participants are the main body responsible for decision-making, participants must rely on the decision to make their payments to maximize. Participants may be composed of individuals and groups.

In order to facilitate the system analysis, includes not only the people involved in the general sense, in game theory, "natural" exists in the virtual participant. When the information is incomplete, natural selection participants in the game. For the general participants, the difference is, as a participant in the

virtual, "natural" does not have the pay and objective function of corresponding, that is to say, to nature, there is no difference between the results of all. In this paper, using N to represent natural, with $I = 1, \dots, N$, represent participants.

Action: action corresponds to the participants in the game process, when nodes appear in a game, and the decision variables corresponding to the participants. In general, the I in an action with AI said, if you want to express the set of all the available I choice of action, denoted by $A_i = \{a_i\}$. The result of action, and can be connected, can also be discrete.

In a game of n person, with the combination of actions is represented by the n individuals involved in the action of the set $a = (a_1, \dots, a_n)$, among them, AI said in the I element action. Here, there is a problem of relationship between action and is involved in the operation sequence. At the end of the game, one of the crucial factors to influence the results is the action sequence. In fact, different action sequence difference between dynamic and static game is made. We can see that, for those who participate in game, although have the same combination of actions, but when the selected action order is not the same, choose the best will correspond to different participants, is the result of the game is not the same.

The information: information is involved in the game of knowledge, especially associated with natural selection, and other participates about knowledge of action and characteristics. In game theory, in order to describe the basic characteristics of participants, description the concept of information set, information can be set that is in a specific moment, the participant to the variable value knowledge.

The strategy: the strategy is participants in certain information set condition selected action rules, strategy identified the involvement people in the choice of what kind of action at when. In the centralized information relates to a participant on before the relevant participants other action knowledge, participants can be determined according to the strategy for the involvement of other people how to make action decision, so people see what can be done according to the strategy, participation.

In general, said the I in a particular strategy with S_i for the actual, corresponding to the I in the strategy combination is $S_i = \{s_i\}$. If the N participants, a total of selection strategy in N, it will form a strategic combination, using n-dimensional vector expressed as: $s = (s_1, \dots, s_n)$

The payment: payment in game theory mainly refers to base on the specific strategy combination, obtained by the utility level. The basic characteristics of the game, to a participant, the payment has to depend on the strategic choice, on the other hand is also affected by the strategic decision related in other people's strategic choice, for all the people involved in the formation of functional relationship.

The results (outcome): the game analysis is more interested in the result, such as balanced actions combination, balance strategy combination and the equilibrium payoff combination.

The equilibrium (equilibrium): a balanced representation of all people involved in the game the best strategy combination, general with $s^* = (s_1^*, \dots, s_n^*)$ as equilibrium.

3 Analyses on Credibility Construction Game

If the transactions of enterprise and consumer are a one-time, then enterprises selling products will have two choices: one is honest, the other one is a dishonest; consumers also have two choices: one is to buy, one is not to buy. So the four possible strategy combination: 1 enterprise trustworthiness, consumers purchase; 2 enterprise trustworthiness, consumers do not buy; 3, the enterprise is not trustworthy, consumers purchase; 4 enterprises are not trustworthy, consumers do not buy. In different market environment, enterprises and consumers have different market behavior.

(1) Assume that the business incredibility will not be punished

First, corporate incredibility will not be penalized; severely damage the interests of consumers, but the income is still positive.

		enterprise	
		trustworthy	not trustworthy
customer	buy	100,100	50,150
	do not buy	0,0	0,0

Figure 1 Payoff Matrix

Assume that trustworthy and their income is 100, and consumers buy genuine products, its revenue is 100; nor punished when the enterprise is not trustworthy because of its deceiving consumers, their

income will be increased to 150, and consumers to buy low-value products, income for 50 (still available).

As shown in figure 1, the first column data of payoff matrix is the consumer's income, the second column data is the enterprise's income. In this environment, from the perspective of enterprises, consumers buy, the optimal choice is not trustworthy; consumers do not buy, the best choice is to be dishonest or trustworthy; from the consumer point of view, enterprise credit, the optimal choice of consumers are purchase, enterprises do not keep promise, optimum choice of consumers are buying because the commodity is a must for consumers, and the quality of goods is not too bad, still have some positive effect. In this one-shot game situations, the equilibrium is that (consumer purchase, enterprise does not keep the credit), transaction can still occur, but the consumer interests have been violated.

Second, enterprise incredibility, will not be penalized; severely damage the interests of consumers, income is negative

If the enterprise trustworthiness, the yield is 100, and consumers buy genuine goods at a fair price for the product, its yield is 100; when the enterprise is not trustworthy due to deceive consumers and not be punished, the revenue will be increased to 150, and consumers due to buy useless products, earnings for the -50 (product useless).

In this case, from the perspective of enterprises, consumers buy, the optimal choice is not trustworthy, consumers do not buy, the best choice is trustworthy or not trustworthy; from the consumer point of view, enterprise credit, the best choice is to buy; enterprise does not keep the letter, the best choice is not to buy. Equilibrium is (do not buy, not trustworthy).

(2) It is assumed that the enterprise incredibility will be punished, but to a lesser punishment

First, corporate incredibility will be punished, but to a lesser punishment; damage to the interests of consumers, but the benefits are still positive.

Assume that trustworthy and their income is 100, and consumers buy genuine products, its revenue is 100; when companies are not trustworthy deceive consumers income will be increased to 150, assuming that the deception consideration of -20, then business revenue becomes 130, and consumers to buy low-value products, income is 50 (still available).

From the business point of view, consumers purchase, the optimal choice is bad faith, consumers do not buy, the optimal choice of bad faith or trustworthy; from the consumer point of view, enterprise trustworthy, the optimal choice of the consumer are purchase, enterprises do not keep promise, the optimal choice of the consumer are also purchase, in this case, the equilibrium is (consumer for purchase, bad faith enterprise).

Second, the interests of consumers with the great damage, negative effect.

If the enterprise trustworthiness, the yield is 100, and consumers buy genuine goods at a fair price for the product, its yield is 100; when the enterprise does not keep your words to deceive consumers benefit will increase to 150, if cheating price for -20, then the profit becomes 130, consumers buy products because useless, earnings for the -50 (product useless).

In this case, from the business point of view, consumers buy, the optimal choice is bad faith, consumers do not buy, the optimal choice of bad faith or trustworthy; from the consumer's point of view trustworthy, the best option is to buy; companies are not trustworthy, the best option is not to buy. Environment is generally not disloyal, rational consumers expecting companies is not trustworthy, the final choice of consumers are not to buy.

(3) It is assumed that the enterprise will be severely punished incredibility

First, when corporate incredibility will be severely punished; damage to the interests of consumers, but the benefits are still positive

Assume that trustworthy and their income is 100, and consumers buy genuine products, its revenue is 100; income will increase to 150 when the companies are not trustworthy deceive consumers, assuming that the consideration for the deception -200 (be severely punished), then the income becomes -50, and consumers buy low-priced products, revenue was 50 (still).

From the business point of view, consumers to buy, the optimal choice is trustworthy, consumers do not buy, the optimal choice is trustworthy or bad faith; from the consumer point of view, and trustworthy enterprises, the optimal option is to purchase, corporate bad faith, the optimal choice of consumers is to buy. Given consumers purchase, the optimal choice is trustworthy, balanced (purchase, keeping promises).

Second, the interests of consumers have a lot of harm, the utility is negative.

Assume that trustworthy and their income is 100, and consumers buy genuine products, its revenue is 100; income will increase to 150 when the companies are not trustworthy deceive consumers,

assuming that the consideration for the deception is -200, then business revenue becomes -50, and consumers buy useless products, gain of -50 (useless).

In this case, from the perspective of enterprises, consumers purchase, the optimal choice of enterprise is a trustworthy, consumers do not buy, the optimal choice of enterprise is a trustworthy or not trustworthy; from the consumer point of view, enterprise credit, the best choice is to buy; enterprises are not trustworthy, the best choice is not to buy. In a generally good credit environment, rational expectations to the enterprise are faithful, finally selection of consumers is buy, enterprises will be trustworthy.

4 Conclusions

When the market environment and institutional environment fail, enterprises dishonesty will not be penalized or only receive a lighter punishment, enterprises choose not to keep credit. At this time, the market will have two kinds of situations, one is the interests of consumers have been infringed, but the deal still occurs; the other one is transaction does not occur. The first case is a lot of fake and shoddy goods on the market, poor corporate integrity, but consumers still buy goods, the transaction will still occur. The economic consequences of the second case are the consumer money in the bank, resulting in the enterprises' products can not be sold, market consumption is not enough, and the whole society's consumption scale is less than optimal. When institutional environment constraints of the market environment is effective, enterprises have an incentive to choose trustworthy, Fair happens, consumers get bigger utility, enterprises get larger gains.

The key of market credibility construction is institutional environment.

Research on the Grain Processing Industry in the Central Region of China*

Li Minjing

School of Economics and Management, Wuhan Polytechnic University, Wuhan, P.R.China, 430023

(E-mail: liminjing920@163.com)

Abstract: The implementation of strategies for boosting the rise of Central China gives a rare opportunity for the development of grain processing industry of Central Region. The development of Grain Processing Industry will improve the grain production level of Central Region and even that of whole country. This paper analyses the grain processing effects on food production, introduces the current situation of grain processing industry through a lot of data and depth study the existing problems of grain processing industry in Central Region, and puts forward some proposals to promote the development of grain processing industry in Central Region.

Key words: Central Region; Grain processing industry; Grain production

1 Introduction

Grain is the foundation of economic development, social harmony, and national independence. Furthermore, it relates to the economic independence and security, the social stability, and the realization of well-off society. Since 2004, the *Central No.1 Document* has proposed to accelerate the development of agricultural product processing industry, including the grain processing industry. In 2008, after the adjustment of tax directory of the primary processing of agricultural products, the tax burden of the grain processing enterprises was greatly reduced. In 2009, the *State Council opinions on further promoting the development of small and medium-sized enterprises* gave a key support to the development of these enterprises, and the macro environment for the development of grain processing industry was gradually improved. *Grain and oil processing industry in the Twelfth Five-Year Plan*^[1] and *Grain processing industry development plan (2011-2020)* were enacted in 2012, which provided a solid policy foundation for the further development of the grain processing industry.

As China to further strengthen policies to aid agriculture and to benefit farmers, grain processing industry is increasingly concerned by many relevant researchers. Ding Shengjun^[2] studied on the decision power for driving the development of grain processing industry is the ability of science and technology innovation, and the guiding ideology, basic principle and correlation content of science and technology integration innovation for grain circulation will be expatiated. Li Lite^[3] pointed out that agricultural products processing has already been a bottleneck which restricted the agricultural development. The primary outlet of agricultural products and grain processing is industrialization of dining table food. Wang Chunhua^[4] researched the problems and causes of food processing industry of China, and gave some countermeasures to solve the problems. Meanwhile, the *Plan to boost the rise of Central Region*^[5] was discussed and passed by the State Council on September 23, 2009. It is clearly noted that the government should focus on strengthening the building of grain production bases, improving the agricultural comprehensive production capacity, and building the Central Region as the grain production bases with high and stable yield. So, this paper researches on the problem of grain processing industry in Central Region has important theoretical and realistic significance.

2 Effect of Grain Processing on Food Production

2.1 To regulate the balance between grain supply and demand

Grain Processing is a balance between grain supply and demand. In developed countries, grain processing industries can make a timely processing of the superfluous food, which is good to keep a stable grain price and to ensure the peasants' production can be timely afforded financially. Thus, a good circle, from production to consumptions and stimulating reproduction, will be formed. Especially at present, conditions of food productions are further improved, so the development of food processing industries is an important way to prevent the situations that there is no food to be purchased or a huge price fluctuating.

* This paper is supported by the Humanities and Social Sciences Research Projects of Hubei Province Educational Department (NO. 2012Q169) and Scientific Research Projects of Wuhan Polytechnic University (NO. 2011&55).

2.2 To effectively promote the circulation of grain

Food processing industry is an important part of developing modern agricultures. The development of grain processing industry can effectively link up the food industry chain, promote food production, and increase the income of farmers. At present, the state has put forward a series of preferential agricultural policies, the relationship between grain supply and demand continues to improve, and the food supply is abundant. So speeding up the development of food processing industry has become more urgent.

2.3 To improve the people's living standards

Food processing industry affects thousands of households' living and their daily meals. The improvement of people's living standard has put forward higher demand for it. The food processing industry also plays an important role in the realization of the convenience main food, the formation of convenient and quick market supply system, and the improvement of food structure.

2.4 To solve the "Three Rural Issues"

The main methods to solve the "Three Rural Issues"(the problems about agriculture, rural areas and peasantry) are the development of food processing industries and the improvement of agricultural industrialization. Through the deep processing of food products, the added value of food products and the comprehensive utilization rate of food resource will be greatly enhanced. Thus, a new way to increase the grain yield and the farmers' income is opened up. The development of food processing industries has double effects on increasing the employment of rural labor force and carrying forward the advantage of agricultural resources. Since food distributing centers are always in small towns, the food processing industry can improve the construction of those towns, as well as the developments of the tertiary industry to absorbing more labor forces.

3 Current Situation of Grain Processing Industry in Central Region

3.1 Production capacity of grain processing industry in central region

The data in Table1 shows that the annual production capacity of unhusked rice and wheat of Central Region in 2010 accounted for the proportion of the nation's total is 46.4% and 43.8%, respectively. It is almost close to half of the nation's total, which indicating a higher proportion of rice and wheat in Central Region. The proportion of soybean production capacity is 5.6%, relatively low. In general, the production capacity of the grain processing industry in Central Region is high^[6-7].

Table 1 2010 Annual Production Capacity Summary Table (units: 10,000 tons)

Region	Unhusked Rice	Wheat	Soybean
Shanxi	11.4	300.5	62.8
Anhui	2448.3	1427.5	50.1
Jiangxi	3016.6	13.0	1.5
Henan	524.4	4699.2	214.0
Hubei	2996.2	507.6	69.0
Hunan	2294.3	41.0	0.9
Central Region In Total	11291.2	6988.8	398.3
Nationwide In Total	24339.3	15953.7	7063.6
Proportion of Central Region to Nationwide	46.4%	43.8%	5.6%

3.2 The yield of grain processing products in central region

It can be found in Table 2 that the processed rice accounting for the proportion is 52.7%, which is more than half of the nation's total, ranked first; the second is the grain food processing products, the proportion is 47.6%;the third is wheat processing products, the proportion is 44.3%, which is close to half the level of the national total; and the fourth is cereals and potato processing products, accounted for only 32.7%; the last row is the corn processing products, only 13.8%, less than 15%. As it can be seen, the yield of processed grain products of Central Region is good in 2010^[6-7].

Table 2 2010 Grain Processing Products Yield Table (units: 10,000 tons)

Region	Rice	Wheat flour	Corn processing products	Grain food	Grains and potatoes
Shanxi	2.1	51.1	69.2	1.0	0.5
Anhui	961.1	744.2	155.0	126.0	18.8
Jiangxi	940.8	1.8	3.5	38.3	1.2
Henan	201.5	2297.9	231.5	152.8	34.4
Hubei	1062.4	214.1	6.2	102.4	19.6
Hunan	678.9	23.0	0.6	78.4	23.6
Central Region In Total	3846.8	3332.1	466	498.9	98.1
Nationwide In Total	7294.8	7528.6	3373.7	1047.2	299.9
Proportion of Central Region to Nationwide	52.7%	44.3%	13.8%	47.6%	32.7%

3.3 Major economic indicators of grain processing industry in central region

Table 3 2010 Main Economic Indicators Summary Table (units: 100 million RMBYuan)

Region	Total industrial output value	Industrial added value	Product sales revenue	Export delivery value	Total profits and taxes	Total profit
Shanxi	68.0	7.9	66.7	0.2	2.7	2.3
Anhui	1044.1	118.4	1025.4	14.7	37.0	26.5
Jiangxi	558.3	57.3	559.5	1.6	14.0	11.2
Henan	1224.6	141.1	1185.7	2.7	44.5	31.9
Hubei	1010.1	258.4	987.4	4.7	34.7	24.8
Hunan	642.7	77.0	625.1	1.1	22.8	18.1
Central Region In Total	4547.8	660.1	4449.8	25	155.7	114.8
Nationwide In Total	15408.9	1994.1	15283.8	194.1	624.8	432.8
Proportion of Central Region to Nationwide	29.5%	33.1%	29.1%	12.9%	24.9%	26.5%

In 2010, the total industrial output value of grain processing enterprises in the Central Region is 454.78 billion RMB Yuan and its proportion is 29.5%, industrial added value is 66.01 billion RMB Yuan and its proportion is 33.1%, sales income is 444.98 billion RMB Yuan and its proportion is 29.1%, the export delivery value is 25 billion RMB Yuan and its proportion is 12.9%, profits and taxes amounted to 15.57 billion RMB Yuan and its proportion is 24.9%, total profit is 11.48 billion RMB Yuan and its proportion is 26.5%. The data in Table 3 show that the nation's total industrial added value is the best, followed by industrial output value and sales income^[6-7].

4 Problems of Grain Processing Industry in Central Region

4.1 The development mode is still scalable

The development of the grain processing industry has brought a series of new atmosphere to the Central Region's economy; there have also been a lot of problems. Such as the small-scaled grain processing enterprises, extensive mode of production and operation, low development, scattered layout, the relative surplus of primary processing capacity, and the low capacity utilization of paddy and wheat processing industry. It not only has the backward production capacity which needs to be eliminated, but also has the structural overcapacity which is caused by the single product type, and the regional overcapacity which is caused by the unreasonable industrial layout. Overall, the relative overcapacities, the waste of resources by the redundant construction, and the other issues have appeared in various degrees driven by market forces. Although, it initially appeared processing leading enterprises group,

but the quantity is still low, the majority is still the small and medium-sized enterprises with weak market competitiveness.

4.2 The quality standard system is imperfect

Quality standard system, inspection and monitoring system, grain safety and quality certification system of grain processing industry are not perfect. Technical requirements of some products are low and lack of uniform standards. Grain hygiene and safety supervision system needs to be further established and improved. Testing instruments of grain quality monitoring department at all levels are relatively backward, the capacity of grain quality and safety testing is weak, and the quality traceability system from raw materials to product has not yet been established. Some enterprises have the weak awareness of law and sincerity, illegal use of grain additives, adulterated, shoddy phenomenon are still existing. Grain safety incidents often happens, the level of grain safety needs to be improved.

4.3 The technology innovation is weak

Grain processing enterprises pay less attention to scientific and technological research and development (R&D). The investment is insufficient, the technological innovation system is not perfect, the basic research is weak, the number of innovation platforms (national engineering technology center, laboratory and enterprise R&D center) is small, and the independent innovation ability of the enterprise is low. Some of the key detection technologies and equipments are relatively backward, risk assessment and control technologies are not widely used, safety assessment of new products are lacking. Enterprises as the mainstay of technological innovation system are not yet fully established, so the innovation capability of enterprise is weak, and the core technology is far behind the world's advanced level. Because the production equipments are obsolete, which seriously affects the market share of grain products and the development of grain processing industry in Central Region? Lack of creative talents and management personnel, most of key technologies and equipments are in the imitation stage, the reserves of scientific and technological achievements are less, and the transformations are slow, the technological content of products is low, high quality products are less. All of these restrict the upgrade of grain processing industry.

4.4 Processing regulation mechanisms are inadequate

Modern grain processing system has not yet been established. Grain processing enterprises are small-scale, quantitative, scattered layout, extensive management, low industry concentration, and irrational industrial structure. The overall development levels of them are not high. The effective convergence of grain processing, production, distribution, consumption and other aspects are not close, the dynamic mechanism to adjust the balance between supply and demand of grain processing has not been formed. Grain industry chain is still mainly based on the grain production supply chain, the downstream processing demand still can not form effective planting instructions, but this supply relationship has restricted the development of downstream processing sectors. The main grain production is relatively backward, small workshops and intensive modes of production are still the mainstay of the market, the grain emergency processing system has just started.

5 Conclusion

5.1 Increase the preferential policy support

To effectively implement the transformation of value-added tax policy, the research and development costs of new products, new technology, new technology credit income tax policy, and the imported foreign technology and equipment shall be exempted from import duties policy. The key grain primary processing enterprises shall be exempted from enterprise income tax. To continue implementing the various preferential policies is to support the development of the grain processing industry. For the technology upgrading, key equipment localization, staple grain industrialization, emergency processing system, major technical innovation and industrialization these key projects, it can take the national discount or subsidies to support them. Effectively implement the grain processing industry tax relief, credit and other preferential policies, and actively guide social capital to invest in the field of grain processing industry.

5.2 Improve grain quality and safety supervision

The problem of grain security is the most concerned and the most direct livelihood issue for the people and it is the lifeline for the development of grain processing industry. Establishing and improving the quality standards system and the quality safety inspection system to ensure the quality and safety of grain products. Guiding enterprises to establish the quality assurance system and the quality security system of the whole process from raw materials to finished products, and promote the healthy

development of grain industry. Enhancing the capacity-building of grain security and detection monitoring are helpful for constructing a complete industrial chain system covering multiple aspects from farm to table. Establishing strict risk monitoring and risk assessment system, access system, and recall system, to make the development of grain processing industry in Central Region into the security-oriented track.

5.3 Enhance the science and technology support

At present, the independent research ability of the grain processing industry is still relatively weak. The Central Region should strengthen the basic research to support the development of intensive and efficient utilization technology, cleaner production technology, saving energy and reducing consumption technology. Meanwhile, it should accelerate the industrialization of high-tech achievements, and make full use of the integration of excellent traditional technology and high-tech to promote the progress of science and technology of grain industry. In addition, cultivating grain processing industry technology innovation platform and R & D base, and attaching great importance to the development of the grain processing equipment manufacturing industry, both play a decisive role in the development of the grain processing industry in Central Region.

5.4 Strengthen the government's macro-control

All local governments must publish the related policy for the development of grain processing industry according to law. And timely put forward industrial investment guidance to make the enterprise clearly knew the encouraged, restricted and prohibited investment projects, and avoided blind and repeated construction. Enterprises should be encouraged to carry out the reorganization of assets through equity participation, holding, mergers, alliances, joint ventures, cooperation and other forms. A group of large modern grain processing enterprises should be trained with high technical level and the national competitive ability to enhance the competitiveness of enterprises. At the same time, we should continue to strengthen the monitoring work of grain processing capacity, and to further strengthen the statistical work of grain processing industry. Completing the statistics of grain processing industry, mastering the basic situation of grain processing enterprises in Central Region, and continue to revise and improve statistics system and index system of grain processing industry.

Analysis on Logistics Infrastructures Site Selection Model

Xun Wei

Harris Logistics Investment Limited Company (Beijing Office), Beijing, P.R.China, 100025
(E-mail: xunwei@vip.sina.com)

Abstract: Logistics network infrastructure location is not just a simple issue to determine the logistics infrastructure location, it affects all aspects of enterprise management and it has an important influence on the survival and development of some an enterprise. This paper briefly describes the significance of the model in logistics infrastructure location, and respectively discusses the general steps of model methods adopted in single logistics infrastructure location and multiple logistics infrastructure location. Then there is comment on various kinds of model methods. At last, the paper puts forward that we should pay more attention to how to combine computer simulation with operators' experience in model method, and make it more convenient for managers and analysis to use.

Key words: Model method; Single logistics infrastructure location; Multiple logistics infrastructure location.

1 Introduction

With the accession into the WTO, modern logistics in China possesses a great development opportunity^[1], and the logistics network infrastructures (LNIs) should be re-engineered for the improvement of the effectiveness of the urban logistics system^[2].

Logistics network location problem is one of the most important logistics management strategic problems and it plays a key role in the whole logistics system. Logistics network location is not only to determine the number and the location of infrastructures, as well as some specific related network schemes. Logistics hub, central distribution center, cross docking center, regional distribution center and distribution center are the important areas of LNIs^[3].

For a single enterprise, the whole logistics system and other structures are determined by the network planning. And, in turn, other planning, such as inventory, transportation planning can also affect the location decisions. Therefore, site selection and have close relationship with inventory and transportation costs.

As to inventory, if the number of infrastructures in a logistics system is gradually increasing, it must result in the increase of the inventory cost. So, for logistics managers, a merger, reducing the number of infrastructures and increasing the size of the infrastructure is important measures to reduce inventory costs. That partly explains why managers often build so many logistics parks and logistics centers to realize the mass distribution.

As to transport, the increase in the number of infrastructures, such as the distribution center, can reduce the transportation distance and reduce the transportation cost. But when the number of infrastructures increases to a certain amount, increasing the frequency of transportation will result in an increase in transportation costs since a single order quantity is too small. Therefore, determine the reasonable number of infrastructures is also one of the main tasks of the location planning.

In conclusion, logistics network infrastructure decisions are not just a simple issue to determine the logistics infrastructure location, it affects all aspects of enterprise management and it has an important influence on the survival and development of some an enterprise.

In this paper, we respectively discuss specific steps and model methods of single or comprehensive logistics infrastructure location decision.

2 Single Logistics Infrastructure Location Problem

2.1 General steps of single logistics infrastructure location

Single logistics infrastructure location usually includes the following main steps:

The first step is to definitude objectives.

Enterprise must make it clear before logistics infrastructure location that setting up a new infrastructure in a new location conforms to the goal and operation strategy of enterprise development, and can bring bigger profits for enterprises. Once the goals are clear, the corresponding leaders should prepare for location decision.

The second step is to determine the preliminary alternative schemes (feasible solutions).

It is involved in collecting data, preliminary screening and arrangement of influence factors according to their importance to the model methods, and making intelligent trade-offs, etc. If necessary, it is reasonable to consult experts, relevant departments and the public opinions. On the basis of the collected data, we can list the factors, then carry on the processing and screening, and identify priorities for tradeoff. Finally, we should make goals relatively concentrated and draw up several preliminary alternative schemes.

The third step is introduction of model method and making a detailed analysis of the preliminary alternative schemes.

Analysis methods used here can be qualitative or quantitative, which fundamentally depends on the factors to consider. For example, transportation cost, construction cost, labor cost can be completely quantified, so these factors can be directly compared and analyst by calculation. While other factors, such as living environment and cultural atmosphere can only be qualitatively analyst, or we can also use classification weighting methods to make an artificially quantitative analysis. Of course, some factors can be qualitative and quantitative at the same time, such as the location measurement method, etc.

The fourth step is making comprehensive comparison to determine the optimal conclusion (optimum).

After the detailed analysis on each alternative scheme, we can get the quality comparison between solutions, or find other better solutions. Then we can select the final plan and prepare detailed proof materials to submit to decision makers for approval.

2.2 Common single logistics infrastructure location model methods

The commonly used single logistics infrastructure location methods include comparison method, orthocenter method, and so on.

(1) The comparison method

This is a simple method of infrastructure location, and it is especially adapted to the comparison of non-economic factors. When several site solutions are similar in terms of cost and benefit, the non-economic factors could be the key factor. At this point, the method of comparison between advantage and disadvantage of several schemes can be used for analysis and comparison.

(2) The orthocenter method

The orthocenter method often used for warehouse selection, the main consideration is the distance between the existing infrastructures and the amount of the goods which are transported. In the simplest case, we assume that the costs of outgoing transport and transport are equal in this method.

At first, we should consider the issues in a two-dimensional coordinate system. The establishment way of the coordinate can be determined by the specific needs, (for example, international location is often established by latitude and longitude coordinates). The original location and the destination should be marked in the coordinate system to determine the relative distances of each point. So, we can get the location which is corresponding to the point whose coordinate is the center of gravity as the optimum choice.

2.3 Comment on the model method of the single logistics infrastructure location

First, we must have a sober understanding of the function of model. We should make it clear that there is no any kind of model is suited for all of the features of location selection. It is impossible to immediately find the final decision once we get the model solution. Therefore, the model can only provide guidance for location decision. We should fully understand advantage and disadvantages of the model method to make full use of it.

The advantage of single infrastructure location problem in the model method is obvious. Model can truly reflect the actual problem, so it has practical reference significance for management solution.

But like many other practical fields of social science, we adopted many assumptions in the model, and the actual situation is simplified. The simplification will inevitably affect the authenticity and applicability of the final result, which is the main defect of the model method.

In general, assumption and simplification of the model are summarized as following.

(1) The assumption of the destination. The number of the demand is often assumed to focused on one point, while the actual demand comes from dispersive and numerous places, which can lead to some calculation error since the calculate the transportation cost is based on a single place rather than to the actual single points.

(2) Variable cost hypothesis. In this type of site selection model, the location is often selected according to the variable costs. In this assumption, there is no difference between the capital cost needed for the warehouse construction in different locations, as well as for other costs which are used in operating in different locations (such as labor cost, inventory holding costs, and so on).

(3) Hypothesis of linear transport rate (Ronald H.B allou, 1973). In the analysis of total transportation cost, we usually assume that the freight rate is proportional to the distance. However, in fact, most of the freight rate is constant, and the rest can increase according to the distance (Ronald H.B allou, 1993).

(4) The assumption of straight line route. In the model, the routes between warehouse and other network nodes is usually assumed as a straight line. In fact, it rarely happen. Since transportation always proceed in a certain road network, in the existing railway system or in loop line around city streets within the network. In practice, in order to respond to this situation, we can introduce a scaling factor, which can help us to turn the linear distance into approximate mileage of highway, railway and other transportation networks. For example, adding 20% to the calculated linear distance can get highway direct line mileage, and 24% are short railway mileage. If it is a city street, the general scaling factor can be 41%.

(5) "Static state". There is no time dimension in this type of site selection model, thus it can't reflect the change income and cost that may cause influence in future.

3 Multiple Logistics Infrastructure Location Problem

Fixed infrastructure location problem is a important strategy scheme in the whole logistics network, and it determines the pattern, structure and shape of the entire logistics system. At the same time, the single infrastructure site selection planning in the real logistics network system is relatively few, while the multiple infrastructure location, which is installed many logistics in structures in some a certain area, can be found everywhere^[4,5].

3.1 Common model methods for multiple logistics infrastructure location

3.1.1 Accurate method

Accurate method is a general term of a kind of method, these methods can get optimal solution by accurate using quantitative analysis, or its accuracy can be quantitative evaluation of the solution.

Obviously, in the point of the accuracy of the results, this method is perfect. But pursuing high accuracy must result in a loss of efficiency. At the same time, the background, definition and description of some practical problems can't be quite accurate. In this case, the pursuit of accurate results can turn out the opposite outcome.

Specifically, the following multiple centers method and other mathematical programming methods can be classified as one of them.

(1) Multiple centers of gravity method

The method is a continuation of the precise gravity method of single infrastructure location problem which is mentioned above. In fact, this kind of thought also has a deep root and a wide range of applications in statistics.

If the points we need to locate are not single, it's necessary to assign the designed locations in the warehouse to the beginning and the end of the logistics points in advanced. Thus formed several commencement and termination communities whose amount is equal to the amount of the designed warehouses. Then, we can use precision orthocenter method to find out centre of gravity of each commencement and termination community.

There are many commencement and termination point allocation method for warehouse. One of them is the "shortest distance method", which combined the nearest points to find out the location of centre of gravity of each community, then redistribute each point to the location of known warehouse, and get the revised center of gravity position of each community, then iterate until the renew position no longer change.

With an increase in the number of warehouse, transportation cost of logistics system will gradually decrease. While the total fixed cost and inventory holding costs will rise. The optimal solution of multiple orthocenter method is the solution of minimizing the sum of all of these costs.

(2) The mixed integer linear programming

In fact, most of the warehouse site selection problem can be described as follows:

Determining the number, scale, and location of warehouses in logistics network to minimize the linear variable cost and fixed cost during delivery of all products to the lowest with the restraint of following conditions:

The workload is no more than the supply of each factory capacity;

- ① All of the product requirements must be met;
- ② The throughput cannot exceed the capacity of each warehouse.

- ③ The warehouse can't start work before the cargo handling capacity is smallest.
- ④ The products consumed by the same consumer must be supplied by the same warehouse.

For planners with operational research background, such a situation is very basic and common. This is just a routine problem can be solved by linear programming - transportation model.

For composite infrastructure location problems, such as a multiple distribution centers location problem for a company who has multiple factories or warehouses, linear programming transportation, makes the minimal method can be used to minimize the total freight costs of all infrastructures. In fact, the advantage of linear programming in the whole network demand allocation process is obvious. Mixed integer linear programming method absorbs the advantages of linear programming, and takes the fixed cost into consideration, which comes from the thoughts of integer programming and formed a kind of model method which has unique advantages.

At present, the scientific management level is relatively low in many local companies of China, and a lot of related work can't be accurate quantification. This situation make it to be a trend that you must pay more on the data acquisition and preprocessing if you want use more "advanced" theoretical model method. So the model method like mixed integer linear programming method will be more popular. We will use this method in the following case.

3.1.2 Simulation method

As mentioned in the preamble, although the precision of the optimal solution provided by the mathematical location model seems to be convincing, but it must make a series of assumptions and simplification to get an accurate solution, while pursuing high accuracy must result in a loss of efficiency. At the same time, The mathematics aesthetic of accurate models of often prompt logistics system analysts to be "keen on relationships between model, calculation and other quantitative relationships, even the role of the model will be exaggerated, while the issues itself will be ignored, which is meaningless to solving problems, and the pursuit of accurate results can turn out the opposite outcome.

Simulation method can be perfect for this situation. So-called simulation is describing the logistics system with algebra and mathematical logic language, then setting up the model, and reproducing behaviors and activities through the model processing to make people mastering disciplinarian of analysis without building and operating an actual system.

Simulation model and arithmetic location model are different in many aspects. In a word, if the arithmetic model is seeking the best warehouse amount, location and size, then the simulation model is repeatedly simulating all kinds of situations under the premise of given multiple warehouses and multiple allocation schemes to find out the optimal network design method. On the one hand, the simulation method ensures that the description of the problem itself is comprehensive and accurate. On the other hand, it can make analysts taking full advantage of accumulated skills, experience and insight to be thoughtful of various possibilities.

3.1.3 Heuristics

In a sense, it can be said that heuristics is inspired by simulation method. Science precise solution requires a lot of costs, while some valuable experience that people have accumulated in the long-term is often ignored, so people start to think about why we can't change the situation? So they begin to consciously apply the rules that they already grasped to guide analysis and reduce the time and cost spending on computing analysis.

Heuristics can cover any principle and concept as long as these principles and concepts are helpful to reducing the solving time. In practice, we often use heuristics to describe some principles that can assist in solving problems. Whenever we use these practical principles to select site, it can greatly accelerate the process of finding the best solution from the alternatives.

Although heuristics can't guarantee to find the optimal solution, but using this method can make the best of people's subjective understanding of different situations and greatly reduce the requirement of computation time and memory space, so people often use this method in site selection.

3.2 Comment on multiple site selection model

The location selection model has experienced a long development course since the early model appeared in land economics. Now it can easily solve many complicated site selection problems.

More and more large-scale multiple infrastructure location models have been widely applied in the logistics location selection practice now, which does huge help to site selection. This method can be used in many situations, such as large distribution network with hundreds of warehouses, more than 20 kinds of products, 15 factories and more than 200 consumption areas, and supply network with only one

warehouse which is supplied by hundreds of dealers. In the fields of defense, retail, consumer good, industrial product and other industries, this model has been used by many enterprises.

These models provide important basis to solving major policy decision problems of enterprise management. They are powerful, and can be used repeatedly in various forms of logistics network design, and provide the necessary planning details. They cost little in processing, and can bring huge benefits to the consumers. What's more, many enterprises can get the information data required in this model easily.

However, these models haven't been used in practice, the reasons are as following. At first, the problem of "non-linear" relationship should be solved. Like the single infrastructure location problem, the cost of inventory policy, transportation fee structure and purchasing economies may be nonlinear and discontinuous. Promoting accurate and efficiency is still a problem need to be solved quickly.

Secondly, there is a problem about "integration". There are various kinds of model method, so the operators can hardly avoid the influence of choosing which one. The ideal situation is promoting further consolidation related methods, and forming a integrated network planning solution to solve the problem of synchronization inventory, transportation decisions and site selection at the same time, rather than solve each problem respectively.

Thirdly, we should pay more attention to the profit effect in the network design processing because the amount of warehouse calculated by the model method is often larger than that determined under the condition of promoting customer service and minimizing cost.

Fourthly, the model should be convenient for managers and planners to use, which can make the model method used frequently in strategic planning and budget, rather than only used occasionally for strategic planning. This requires that there is close relationship between model and enterprise management information system to get the model data needed for the operation quickly.

All in all, despite the settlement method and applicable scope of the various model methods are different, each model can be used by analysts and managers who have some specific skills to get significant result. The model methods will be more convenient for decision makers in the future.

4 Conclusions

In the above section, we systematically describe the single logistics infrastructure location model method and multiple logistics infrastructure location model. We can see that each model each has its own characteristics through the description of the two methods of model. Therefore choosing proper model is significant for the accuracy of results.

Research on the Implicit Theories of Creativity of Industrial Designers in China

Zhang Hongtao

School of Art and Design, Wuhan University of Technology, Wuhan, P.R.China, 430070
(E-mail: zht19840729@126.com)

Abstract: Professional designers, university teachers and undergraduates in the domain of industrial design were surveyed in this study to explore the implicit theories of creativity of industrial designers in China. The study, conducted through factor analysis, found that the implicit theories of creativity of industrial designers mainly involves the following eight factors: "Agreeableness", "Enterprise", "Exploration", "Wisdom", "Knowledge and skills", "Convergent thinking", "Divergent thinking" and "Challenge". Three groups of respondents in this study highly valued "Agreeableness" and "Enterprise" as contributive factors to creativity, while giving lower priority to creative thinking. In addition, this study also found that there are certain discrepancies in views on the implicit theories of creativity of industrial designers among the three groups of respondents. The above-mentioned discrepancies are likely to reflect a standard difference between employers and universities regarding how to assess creative designers.

Key words: Creativity; Industrial designer; Implicit theory; Explicit theory; Social validity

1 Introduction

Creativity is an important index to judge whether or not a designer is outstanding. However, being rich and complex, the connotation of creativity is not merely an academic concept, but a public concept with realistic significance. Therefore, in addition to grasping the theory of creativity from the academic research perspective, it is essential to know how the public, especially professionals in specific domains, interprets the term "creativity". In fact, it will not only help us testify and supplement the established theories of creativity, but will also help us find out the existing problems in the screening and cultivation of creative talents. From this perspective, this study attempts to conduct a investigation and analysis on the implicit theories of creativity of industrial designers for the purposes of enriching our knowledge on the nature of creativity in the field of industrial design, and providing a solid foundation for the discussions of problems in relation to design education and design management.

2 Literature Review

2.1 The implicit theories of creativity

The famous "Creativity" speech was published in 1950 by Guilford when he was inaugurated as the chairman of American Psychological Association, since then opened the prelude to the scientific study of creativity^[1]. With progress of research, researchers began to notice the influence of environment on creativity, and recognized that creativity is not only a personal attributes, but also a value factor of social assessment. Therefore, the measurement, cultivation and development of individual creativity are closely related to the social context, and the individual creativity also largely depends on the perception, assessment and expectation by the public. Such a view is supported by the Pygmalion Effect and the Labeling theory. On the other hand, psychologists also found that people, at most of the time, reply on experience and intuition rather than rigorous scientific theory as the basis of measuring the individual creativity. As a result, some researchers began to reconsider their research methodologies, and pay more attention to the perception of creativity among ordinary people.

In 1985, the concept of implicit theories of creativity was clearly put forward by Sternberg on the basis of his implicit theory of intelligence^[2]. In his view, explicit theories, which are proposed by psychologist or experts in other fields, refer to a theoretical system of the concept, structure and development of creativity based on large sample tests and data analyses. The implicit theories, also known as "public view", are a set of views, formed in daily life or at work, on the concept, structure and development of creativity in individual minds. In addition, compared to the explicit theories, the implicit theories of creativity embody the attributes of social validity^{[3][4]}, which play an important role in the informal assessment (such as a job interview) and cultivation (such as interaction between parents and children) of creativity in real life^[5].

According to the different research paradigm, Christiane et al. divided the researches on the

implicit theories of creativity into two categories: One focused on the degree of consistency when people were evaluating individuals and products, attempting to reveal the implicit standard of creativity. The other was the study on people's understanding of creative talents, looking for the prototype of creativity in people's minds^[6]. In fact, most researches have fallen into the latter category in the recent 20 years, which mainly focused on the nature, cultivation and influential factors of creativity.

2.2 The implicit theories of creativity in the field of art and design

Interpretation of creativity differs from people in different fields, therefore, the field particularity plays an important part of revelation in the implicit theories of creativity. Helson said, the field most closely related to creativity is artistic interest, followed by the investigation, the society, the enterprise, then is the conventional and traditional field^[7]. Naturally, researches on the implicit theories of creativity in art-related fields have been highly valued by scholars. Sternberg had studied the professor's implicit theories of creativity in art, business administration, philosophy and physics. Results showed that, the implicit theories of creativity among professors in different fields largely overlaps, but professors of art attached more emphasis on imagination, originality and risk-taking^[2]. Runco et al. studied the professional artist and the college student's implicit theories of artistic, scientific, and everyday creativity, and found that there are significant differences between different types of creativity. For example, scientific creativity underlined logic, experiment, patience and thoroughness, artistic creativity focused more on understanding and expressions of emotion, and creativity in daily life placed greater emphasis on meanings, initiative and discretion^[8]. Romo et al. had investigated the implicit theories of creativity of 180 painters from five dimensions: impulse, experimentation, self-seeking, communication and mental disorders. The results found that significant differences could be seen between painters and undergraduates on the implicit theories of creativity^[9].

In the mean time, people's understanding of creativity also differs under different cultural backgrounds. Niu had reviewed the studies on implicit theories of creativity in both western and eastern cultures, and found that despite there were something in common, such as originality, imagination, intelligence, independence, etc., eastern cultures attached more emphasis on the social and moral components in the creativity, while western cultures emphasized sense of humor and aesthetics^[10]. Coincidentally, it happened that there were similar conclusions in the studies conducted by Rudowicz^[11].

Therefore, the author thinks that, regardless of field particularity and cultural background, the implicit theories of creativity will be meaningless. Chinese scholars should not mechanically copy the conclusions of western researches, instead, they should take Chinese as subjects, and explore the implicit theories of creativity in particular fields. This is the theoretical starting point of this study.

3 Method

3.1 Preliminary investigation

Questionnaire with 66 items was adopted in the preliminary investigation.

Items were gathered from two sources: First, items used by Sternberg^[2], Runco^[8], Romo^[9], Westby&Dawson^[12] and David^[13] have been translated and summarized. The other source is the in-depth interviews with 12 professional industrial designers, 6 university teachers and 15 undergraduates majoring in industrial design. Respondents were asked to write down the feature terms as many as possible to describe the industrial designers with high creativity. After that, all items had been analyzed and summarized.

Likert 9 sub-scales (1-9 point) was adopted in the preliminary questionnaire. 73 questionnaires were distributed in Changsha and Wuhan. The respondents included 36 professional industrial designers, 12 teachers teaching industrial design in universities and 25 undergraduates majoring in industrial design. 68 questionnaires were valid. In the process of analyzing and summarizing, items that made respondents feel difficult to understand or confused have been modified or removed, and a formal questionnaire with 52 terms was finally drawn up.

3.2 Formal investigation

626 questionnaires were released in the formal investigation. Respondents in the investigation consisted of three groups of professionals: professional industrial designers, teachers who taught industrial design in universities, and undergraduates majoring in industrial design. These respondents mainly came from 86 companies and 25 universities in Beijing, Shanghai, Guangzhou, Changsha and Wuhan. 589 questionnaires were valid. Demographic profiles of Respondents have been summarized in Table 1.

Table 1 Respondent Profile

	Male	Female	SUM
Industrial designers	114	98	212
University teachers	95	62	157
Undergraduates	85	135	220
SUM	294	295	589

When the questionnaires were reclaimed, the obtained data were calculated and analyzed. Items with a low level of average scores (below five point) has been eliminated. Ultimately, 40 items were retained for further analysis.

4 Results

4.1 Structure analysis for the implicit theories of industrial designer's creativity

The implicit theories of creativity of industrial designers presented an eight-factor structure when a factor analysis was conducted (seen Table 2). This structure was generated with KMO (Kaiser-Meyer-Olkin Measure of Sampling Adequacy, KMO) of 0.864 and was highly significant at the 0.000 level. The total explained variance of these 8 factors accounted for 72.3%, and these 8 factors covered eight distinct aspects of industrial designer's creativity: "Agreeableness", "Enterprise", "Exploration", "Wisdom", "Knowledge and skills", "Convergent thinking", "Divergent thinking" and "Challenge". Among them, the variance of "Agreeableness", "Enterprise" and "Exploration" was more than 10%, which could be regard as three of the most important dimension to interpret the implicit theories of creativity of industrial designers.

Table 2 Factor Structure of the Implicit Theories of Creativity of Industrial Designer

Factors	Item (Factor loading)	% of variance	Cumulative %
Agreeableness	Enthusiasm (0.809), Optimistic (0.775), Confidence (0.828), Amicability (0.770), Generous (0.779), Team spirit (0.874), Tolerance of criticism (0.912)	12.121%	12.121%
Enterprise	Perfectionism (0.829), Diligence (0.818), Conscientiousness (0.812), Persistence (0.861), Ambition (0.810), Concentration (0.790)	10.319%	22.440%
Exploration	A broad range of interests (0.878), Curiosity (0.872), Thirst for knowledge (0.907), Risk-taking (0.889), Assertiveness (0.888)	10.016%	32.456%
Wisdom	Highly observant (0.909), Insight (0.829), Clarity of thinking (0.858), Be good at learning (0.904), Logical reasoning (0.896)	9.927%	42.383%
Knowledge and skills	Information-processing skills (0.898), Erudite (0.767), Practical ability (0.884), Interpersonal skills (0.618), Rich in experience (0.914)	8.691%	51.074%
Convergent thinking	Reasoning (0.873), Pragmatic (0.870), Chariness (0.848), Market-orientation (0.914)	7.911%	58.985%
Divergent thinking	Associative thinking (0.816), Imagination (0.762), Thinking flexibility (0.746), Innovation (0.758), Open-minded (0.822)	7.754%	66.739%
Challenge	Criticism (0.826), Skepticism (0.849), Independent thinking (0.859)	5.560%	72.299%

Table 3 shows a descriptive statistics on the top 10 and the last 10 items in this study. For the 20 items, the means and standard deviations are provided. As we can see, six of the top 10 items came from the "Enterprise" factor ("Ambition", "Concentration", "Diligence", "Perfectionism", "Conscientiousness" and "Persistence"), three belonged to the "Agreeableness" factor ("Enthusiasm", "Confidence" and "Tolerance of criticism"). This result appears to underline once again the importance of "Enterprise" and "Agreeableness" on the creativity of industrial designer.

However, in the last 10 items, 4 items were from the "Convergent thinking" factor ("Reasoning", "Pragmatic", "Chariness" and "Market-orientation") and 4 were from the "Divergent thinking" factor ("Associative thinking", "Imagination", "Innovation" and "Open-mind"). The results indicate that, compared with the creative thinking, professionals is more concerned with whether designers can do

their work with a sense of responsibility, and whether they can live in harmony with the leadership, customers and team members.

Table 3 Descriptive Statistics for the Top Ten Items and the Last Ten Items

Rankings	Items	Mean	Std Dev	Rankings	Items	Mean	Std Dev
1	Ambition	6.54	1.39	31	Information-processing skills	5.75	1.63
2	Concentration	6.48	1.39	32	Innovation	5.74	1.70
3	Persistence	6.41	1.28	33	Open-minded	5.69	1.73

5	Perfectionism	6.34	1.41	35	Associative thinking	5.62	1.71
6	Conscientiousness	6.29	1.41	36	Imagination	5.62	1.71
7	Confidence	6.17	1.10	37	Market-orientation	5.61	1.70
8	Tolerance of criticism	6.16	1.44	38	Pragmatic	5.41	1.71
9	Assertiveness	6.15	1.52	39	Chariness	5.39	1.71
10	Enthusiasm	6.15	1.57	40	Reasoning	5.36	1.69

4.2 Discrepancy analysis on the implicit theories of creativity among the respondents

In consideration of the possible differences in the implicit theories of creativity of industrial designer among professional industrial designers, university teachers and undergraduates, a MANOVA analysis on all of the 40 retained items were applied in the study. As indicated in Table 4, three groups of respondents showed significant divergences in 11 of the 40 items.

Table 4 MANOVA Results

Items	Industrial designers		University teachers		Undergraduates		F.	Sig.
	Mean	Std Dev	Mean	Std Dev	Mean	Std Dev		
Erudite	5.61	1.39	6.07	1.70	5.69	1.92	3.700	0.025*
Interpersonal skills	6.27	1.37	5.76	1.96	5.89	1.99	4.315	0.014*
Insight	5.81	1.37	6.26	1.54	6.13	1.58	4.536	0.011*
Market-orientation	5.86	1.31	5.49	1.80	5.46	1.93	3.584	0.028*
Confidence	5.97	1.22	6.23	1.49	6.33	1.47	3.688	0.026*
Team spirit	6.28	1.30	6.06	1.41	5.90	1.59	3.630	0.027*
Tolerance of criticism	6.34	1.25	6.15	1.45	6.00	1.58	3.206	0.041*

** $p < 0.01$, * $p < 0.05$

In order to explain the differences more specifically, this study also performed a series of Independent sample t-test analyses using the SPSS software for all of the 11 items. Table 5 presents the results of the Independent sample t-test analysis.

As shown in Table 5, significant discrepancies were shown in 5 of the 11 items between professional industrial designers and university teachers. More specifically, professional industrial designers placed greater emphasis on “Interpersonal skills”, “Market-orientation” and “Persistence”, while university teachers attached more emphasis on “Erudite” and “Insight”. Besides, the results suggest near identical implicit views between university teachers and students. Only one of the 11 items (“Erudite”) exhibited significance among the two groups, and the remaining 10 items did not indicate any significant differences. However, large discrepancies could be seen between the professional industrial designers and undergraduates: 9 of the 11 terms differed significantly in these two groups. Comparatively speaking, professional industrial designers appeared to highly value

“Interpersonal skills”, “Market-orientation”, “Team spirit” and “Tolerance of criticism”, while the undergraduates seemed to concern more about “Insight”, “Confidence”, “Criticism”, “Independent thinking” and “Assertiveness”.

5 Conclusion

As a complex psychological phenomenon, creativity has been always regarded as a result of multiple factors in explicit theories. For example, based on Robert Sternberg's Triarchic Theory of Intelligence, he proposed three-faced model of creativity, arguing that creativity was mainly driven by intelligence, intelligence styles and personality^[14]. Teresa Amabile considered creativity as the result of interactions of three factors: task motivation, domain-relevant knowledge and creativity relevant skills^[15]. John Feldhusen argued that creativity consist of three elements: knowledge, metacognition and personality^[16]. In this study, the author found that the implicit theories of creativity of industrial designers consisted of an 8-factor structure when a factor analysis was conducted (see Table 2). It could be observed that these 8 factors could be grouped into 4 categories: Knowledge and skills, Intelligence (“Wisdom”), Personality (“Agreeableness”, “Enterprise”, “Exploration” and “Challenge”) and Thinking (“Convergent thinking” and “Divergent thinking”). The above-mentioned results indicate that there is a distinct correspondence between the explicit theories of creativity and the implicit theories of creativity of industrial designers.

In addition, this study found that, compared with the creative thinking, subjects seemed to more concerned with the importance of “Enterprise” and “Agreeableness” to the creativity of industrial designer. Specifically, factor “Enterprise” involved the following items: “Perfectionism”, “Diligence”, “Conscientiousness”, “Persistence”, “Ambition” and “Concentration”, and the “Agreeableness” factor could be further illustrated by items like “Enthusiasm”, “Optimism”, “Confidence”, “Amicability”, “Generous”, “Team spirit” and “Tolerance of criticism”. Such finding is consistent with Yang's study to some extent. Yang argued that, the presence of collectivism moral and postnatal efforts in the Chinese implicit theories of creativity can be explained by cultural factors^[17]. But this study thinks that this finding was related to the working manner of designers. On the one hand, teamwork is one of the most common work patterns in design companies. In order to accomplish the design projects and pursue high quality, designers have to keep close communication with copy writer, account executives and other colleagues. On the other hand, designers with high “Agreeableness” scores might benefit from the broader social network and gather more information from various resources. Therefore, they may be much easier to get their creative potential inspired and developed.

Finally, this study found that there are certain discrepancies in the implicit views of industrial designer's creativity between professional industrial designers, university teachers and undergraduates. As shown in Table 5, perhaps because the university teachers and undergraduates sharing the same

environment, the implicit views from the two groups are in substantial agreement. However, discrepancies between professional industrial designers and the other two groups are rather large. Since the viewpoint of professional industrial designers is more similar to the objective requirement of the human resources market, such discrepancies are likely to reflect a standards difference between employers and universities in how to assess and cultivate creative designer. And what's more, those discrepancies may result in a number of undesirable effects. For example, a possible labour shortage in the design industry, low employment rate of undergraduates and an enormous waste of educational resources. To sum up, in order to reach a consensus about the nature and influencing factors of creativity in future, it is of great necessity to strengthen the cooperation and communication among design companies, universities and undergraduates.

Research on Coupling Characteristics and Mechanism of Product Innovation Design Risk Conduction

Deng Jun

Wuhan University, Wuhan, P.R.China, 430072

(E-mail: jund@sud.whu.edu.cn)

Abstract: This paper defines two concepts of coupling and the coupling effects of product innovation design risk conduction, it points out that the pure coupling, weak coupling and strong coupling could be happened in the risk of product innovation design because of the risk subsystems' interaction and mutual influence in product innovation design risk conduction, and it reveals the formation mechanism of the strong coupling of product innovation design risk. It guides to prevent the strong coupling of product innovation design risk.

Key words: Product innovation design risk conduction; Coupling effect; Pure coupling; Weak coupling; Strong coupling

1 Introduction

The concept of coupling in physics refers to two (or more) systems or movement forms affect mutually through various interaction. For example, if two pendulums are connected by a spring, each rolling on their vibration and influence mutually, this interaction is called pendulum coupled. If a more spring is added, then their vibration and fluctuation could have new change with the third pendulum. Similarly, In the process of product innovation design risk conduction, due to each process and function node of product innovation design has functional association relationship, and there is the risk of strategy, objective, system, process, quality and intellectual property which has its own characteristics in the process of product innovation design, it could develop its subsystems which interacts with each other and influences mutually, then develop the different matching relationship in the process of its conduction, finally it could change the flow and property of risk conduction. This phenomenon is called the coupling effect in risk conduction. There are two important factors which could determine the property of coupling effects in product innovation design risk conduction - the correlation degree of function node of product innovation design and the matching degree between risks.

2 The Coupling Characteristics Analysis of Risk Conduction of Product Innovation Design

As stated earlier, if we consider the process of product innovation design as a complicated risk system which consisted of many risk subsystems in the process of product innovation design risk conduction, so the status of risk conduction of the whole product innovation design depends on the mode of existence and the extent of coupling of each risk subsystem in the system at one moment.

Assumed that it is confronted with n kinds of risk, we can use variance to describe the existed risk status:

$$\sigma^2 = \sum_{i=1}^n \sum_{j=1}^n k_i k_j \sigma_i \sigma_j \rho_{ij} \quad (1)$$

In the above formula, σ^2 means the risk status of product innovation design, σ_i means the value of risk status of risk subsystem, k_i means the weight of risk system i in the whole risk subsystem set, ρ_{ij} means the relative degree between risk subsystem i and risk subsystem j .

The correlation coefficient ρ_{ij} presents the relative degree of two random variables, in terms of overall risks of product innovation design, the correlation coefficient presents the relative degree and the extent of coupling between various risks in the risk conduction of product innovation design, and it is the interaction force coefficient between each risk subsystem. It depends on the correlation degree between function nodes of product innovation design and the matching degree of risk property. The absolute value of correlation coefficient is less than 1, it means $-1 \leq \rho_{ij} \leq 1$. The value of ρ_{ij} also determines the speed, strength and time of product innovation risk conduction. The different value of

ρ_{ij} could lead to the different coupling effects of risk conduction.

2.1 The pure risk coupling of product innovation design

In the process of product innovation design risk conduction, at some moment coupling could be happened when risk flow i meet with risk flow j, then these two risk flow cross, interact and influence mutually. When the total risk flow after coupled is equal to that before, and the total risk flow remains the same quantity after passing the control node, it could not affect the total risk flow after coupled, it will have the effect of $1+1=2$, this status of coupling could be called pure coupling (Figure 1).

Figure 1 Pure Risk Coupling Diagram

2.2 The weak risk coupling of product innovation design(-1 ≤ ρij ≤ 0)

In the process of product innovation design risk conduction, at some moment coupling could be happened between risk flow i and risk flow j, when the total risk flow after coupled is less than before, it could weaken the total risk flow after coupled, it will have the effect of $1+1 < 2$, this status of coupling could be called weak coupling (Figure2).

Weak risk coupling is caused by the inadaptability between risks and the perfect measures of risk control, the longer the path of risk conduction is ,the weaker the total risk flow of the end, so it is easier to control and prevent risks, and the smaller the loss caused by risks is.

Figure 2 Weak Risk Coupling Diagram

2.3 The strong risk coupling of product innovation design(0 ≤ ρij ≤ 1)

In the process of product innovation design risk conduction, at some moment coupling could be happened between risk flow i and risk flow j, when the total risk flow after coupled is more than before, s it could reinforce the total risk flow after coupled, it will have the effect of $1+1 > 2$, this status of coupling could be called strong coupling (Figure3).

Strong risk coupling is caused by the conflict between risks and the worse measures of risk control, the longer the path of risk conduction is ,the more the total risk flow increases, so the strength will be increased rapidly, so it is harder to control and prevent risks, and the heavier the loss caused by risks is.

Figure 3 Strong Risk Coupling Diagram

3 The Analysis of Formation Mechanism of Strong Coupling of Product Innovation Design Risk Conduction

From the above analysis, in terms of product innovation design, the most concern is the occurrence

of strong coupling in the risk conduction of product innovation design, because ‘strong coupling’ could reinforce the strength of risk conduction, the range of conduction and the speed of conduction, so the total risk of product innovation design will be increased, it has a crippling effect on it. Therefore, the following text will deeply describe the mechanism of strong coupling in the risk conduction of product innovation design.

For the formation mechanism of strong coupling of product innovation design risk conduction, we could learn lesson from the concept of ‘strategic risk coupled trigger’ proposed by Liu Shengfu (2004), it can explain that how the coupling between subsystems can result in disharmony and uncertainty in product innovation design in the light of the principle of trigger, then the strong risk coupling could be happened.

The concept of trigger in physics means that it produces electronic pulses when the electric current and voltage reach a critical value, and then the trigger begins work and initiates the next working procedure. We can use the coupling trigger to test whether the coupling extent between risk subsystems can produce new pulses by stimulating trigger or not, but these pulses will break the linear equilibrium state of risk conduction system, and promote it to break the critical value of equilibrium states, it will increase risks rapidly or change risks, then it will lead to the occurrence of strong coupling.

The occurrence of pulse need meet certain criteria; it need filter and adjust by filter before the occurrence of strong coupling. Filter is also a physics concept; it means the filtering function and self-adjustment function of product innovation design, and the self-organize ability and self-repair ability of product innovation design.

As stated earlier, as a complete system, the product innovation design system has some Characteristics such as self-organize, self-adapt, and self-adjust and risk concentration release. These Characteristics could determine that if the existed risks of product innovation design is in a certain critical value, it can weaken and block risk coupling sets in the product innovation design by self-organize, self-adapt and self-adjust, it could not reach the critical value, so it remains in the state of pure coupling and weak coupling, and risk factors still remain in independent, static and partial states, it could cover and buffer negative effects brought by risks. However, these risks and negative effects have never virtually gone, they are temporarily in a state of covert and slow release. When the risk flows of product innovation design gradually increase, the static state will convert into dynamic state if broken the critical value by risk flows or reduced the critical value by inducements occurred in the environment, the form and intensity of interaction will gradually increase, the final result is that the new form of risks will conduct and spread in the product innovation design system after the risk flow dramatically increased or the coupling changed.

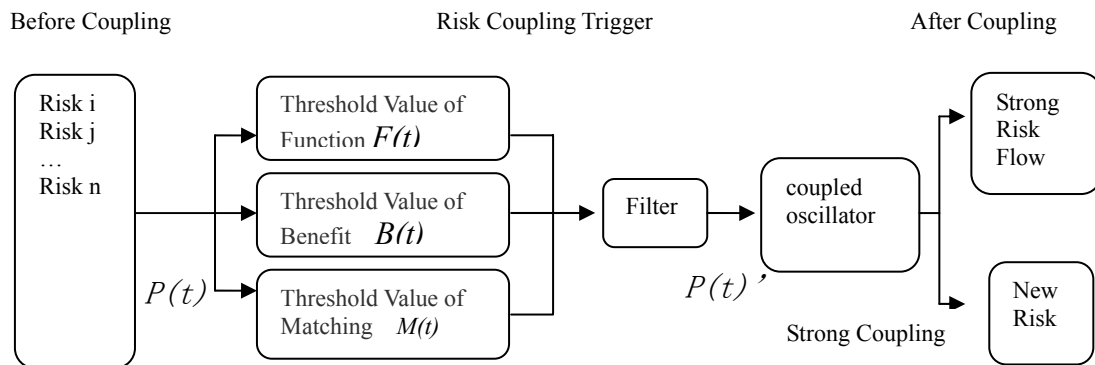

Figure 4 Risk Coupling Trigger Diagram

As described in the above diagram(Figure4).When coupling have been happened in the process of risk conduction between risk subsystems, it starts to produce pulse $P(t)$ and tries to pass the parallel threshold value(threshold value of function F , threshold value of benefit B , threshold value of matching M).when $P(t) > \text{Min}\{ F(t), B(t), M(t) \}$, $F(t)$, $B(t)$, $M(t)$ means the threshold value of function, the threshold value of benefit and the threshold value of matching respectively in the risk conduction, the pulse will pass through the threshold, and then be filtered by the filter, after that the new pulse $P(t)'$ will be generated. The coupling oscillation which generated by the new pulse passed through coupled oscillator will break the linear equilibrium state of risk conduction of product innovation design, it will increase risks rapidly or change risks, then it will lead to the occurrence of ‘strong coupling’.

When $P(t) < \min\{F(t), B(t), M(t)\}$, the pulse could not pass the threshold, and the extent of coupling between risk factors will be weakened by the self-organize, self-adjust and self-adapt ability of product innovation design, it will be controlled in a certain range to make it less than the threshold, therefore risk will remain in a state of 'weak coupling'.

4 Conclusions

In risk conduction of product innovation design, due to all kinds of risk subsystems interact with each other and influence mutually, it generates the dynamic coupling which occurred in the correlation degree of function node of product innovation design and the matching degree of different risks, the coupling effect of risk conduction of product innovation design could be happened.

The different value of correlation coefficient ρ_{ij} will bring about the different coupling effect of risk conduction of product innovation design, when $\rho_{ij} \cong 0$, it is called pure coupling, when $-1 \leq \rho_{ij} \leq 0$, it is called weak coupling, when $0 \leq \rho_{ij} \leq 1$, it is called strong coupling.

The formation mechanism of strong coupling of product innovation design risk conduction could be revealed by the working principle of 'strategic risk coupled trigger'.

Evaluating and Studying Tourism Industrial Structure Benefit of Hubei Province of China *

Luo Xiaoli

School of Management, Changjiang Professional College, Wuhan, P.R.China, 430074

(E-mail: 63209582@qq.com)

Abstract: Tourism Industry of Hubei Province of China has made gratifying achievements and has a certain scale after several years' developments. The problem of the dysfunctional structure has seriously influenced our economic interest. By analyzing problems of tourist structure of Hubei province of China, the author establishes an evaluation model with deviate-quota analysis method, and makes applied researches on tourist structure benefit of Hubei province of China, then proposes corresponding countermeasures and suggestions to optimize tourism industry structure of Hubei province of China on the basis of the analytical results.

Key words: Hubei Province; Tourism Industrial Structure; Benefit; Deviate-quota Analysis Method

1 Introduction

Chinese tourism industry has been growing faster and faster recent years, Hubei tourism industry has also made gratifying achievements. According to statistical information of national tourism administration, Hubei province of China accepted 274 million domestic and foreign tourists and earned 19, 9289 million in 2011, increased by 29.53 percent and 36.45 percent respectively. We can say loudly that Hubei tourism industry has had a large scale and played an important role in national economic system.

In spite of so many achievements, we should see that the objective factors restricting development of Hubei tourism industry haven't changed thoroughly. There's a big gap between Hubei and tour industry developed provinces. There are so many problems brought by its unreasonable inner structure. Research on optimizing tour industry structure of Hubei province of China has important significance for allocating resources rationally and efficiently, coordinating the internal relationship, improving its overall quality, and promoting efficient operation of Hubei tourism industry .

2 Problems of Tourist Structure of Hubei Province of China

The following expressions are about the extrusive difficult and problems of Hubei tourist structure:

2.1 Irrational department structure and backward infrastructure

Department Structure of Hubei tourism industry is still at a lower level, tourist revenue is mainly from high input while low output type, such low investment while high comprehensive benefits departments as tourist merchandise and hotel remain to rise.

Just look at the travel agency of Hubei, the ratio of international to national is not only lower to the national average, but also to surrounding provinces. Look from the lodging hospitality industry, star-grade hotels in Hubei are slightly less, high-grade reception facilities are not enough, which adverse to attracting high-spending tourists. Moreover, cruise ships in Yangzi River are developing rapidly while tourist failed to pick up, the distinctive contradiction between supply and demand of cruise ships cause the cruise business low efficiency and intense price competition, which is a vicious circle.

2.2 The imbalance of tourist regional development

Because of location and traffic factors, Hubei tourism development is of distinctive regional imbalance for a long time. The contradiction of strong south and weak north is prominent. Airports of Hubei province of China are mainly located in Wuhan, Yichang and Enshi, where earn much more tourist revenue than the other areas. Such areas as Shennongjia, Shiyan have much less tourist revenue although they have high reputation just because they have low accessibility which affected greatly their tourist revenue. Low accessibility brings high expenditure. Hubei tourism industry must deal with the problem of equitable distribution if we want to gain the comprehensive competitive advantage.

2.3 Simplistic product structure

* This paper is supported by Hubei education department humanities and social science research project. Project Number: 2010b289 and 2008X001.

Tourism products of Hubei province of China are sight-seeing products such as three gorges and the culture of Three Kingdoms, which are low numbers and simplistic types. Sight-seeing products of Hubei province of China are homogenous competition and generalizing development. Such as three gorges products. Cultural tourism products with characteristics are aging Packed and scattered distribution, such low level development causes upgrading its quality a heavy task. Urban sight-seeing products are less well developed; urban image, landscape reservation and building work are a heavy task. The whole sight-seeing products are lack of sequential combination; we need to rebuild the ultimate, the pick and the important products combo setup.

2.4 Weak international market and low consumption national market

International tourist market of Hubei province of China has the following characteristics: firstly, the total amount is few while develop fast; secondly, foreign market holds a large proportion; thirdly, the Japanese and Korea market looked to further increase by China are not ideal to Hubei; Fourthly, Taiwan market has big fluctuations; Last but not least, the total expenditure of foreign tourist is on the low level. National tourist market of Hubei province of China has the following characteristics: Firstly, the main purpose of traveling is sight-seeing; secondly, 40 percent passengers are from Hubei province of China.

3 Evaluation Model on Effectiveness of Hubei Tour Industrial Structure

We must not only analyze the component part but also the benefit of tour industrial structure. It consists of economic benefits, social benefits and ecological environment benefits. Economic benefits can be reported by increasing income, improving rate of return on capital and expanding tax. This article is mainly concentrating on economic benefits.

We choose deviate-quota analysis method to analyze and evaluate the benefit of tour industrial structure. Concrete details are: based on the annual rate of growth, we guess and estimate a hypothesis, then compare the hypothesis to the actual growth, and then analyze the shift state of Hubei tourist structure to the average level of the whole country. The effectiveness state can be analyzed and judged at last.

According to the Shift-Share Analysis, three factors are related to economic growth of Hubei province of China, those are state factor, structure factor and area factor. Then we can write a formula of economic growth rate.

$$R_{vi} = U_t + V_i + W_i \tag{1}$$

$$U_t = \frac{G_t - G_o}{G_o} \times 100\% \tag{2}$$

$$V_i = \left(\frac{G_{it}}{G_{io}} - \frac{G_t}{G_o} \right) \times 100\% \tag{3}$$

$$W_i = \left(\frac{Y_{it}}{Y_{io}} - \frac{G_{it}}{G_{io}} \right) \times 100\% \tag{4}$$

There into, R_{vi} —economic growth rate of industry i of Hubei tourist industry; U_t —the t th year economic growth rate of national tourist industry; V_i —growth rate of industry i of national tourist industry; W_i —growth rate of industry i compared to national industry i ; G_o —base period revenue of national tourism industry; G_t —the t th year revenue of national tourism industry; G_{it} —the t th year revenue of national tourism industry i ; G_{io} —base period revenue of national tourism industry i ; Y_{it} —the t th year revenue of Hubei tourism industry i ; Y_{io} —base period revenue of Hubei tourism industry i .

According to the formula, if U_t doesn't change, then we can see each industry shift level relative to the whole country, then we can analyze and evaluate the effectiveness of each industry Structure. V_i reflects effectiveness of industry i to the whole industry, if $V_i > 0$, it means industry i growth faster than the whole industry, then its effectiveness is relatively better; While if $V_i < 0$, it means industry i growth slower than the whole industry, then its effectiveness is relatively poor. W_i reflects the comparative advantage of industry i of one place to the national industry i , When $W_i > 0$, the lager the figure is, the bigger industry i competitive advantage is; When $W_i < 0$, the smaller the figure is, the weaker industry i competitive advantage is.

1) If $V_i > 0$, $W_i > 0$, then the effectiveness of industry i structure higher than the average level, it means its effectiveness is relative better and has competitive advantage.

2) If $V_i < 0$, $W_i < 0$, then the effectiveness of industry i structure lower than the average level, it

means its effectiveness is relative poor and hasn't competitive advantage.

3) If $V_i > 0$, while $W_i < 0$, then industry i increases faster than the whole industry, while slower than the same industry of the whole country, it means industry i is lack of competitive advantage to the whole country.

4) If $V_i < 0$, while $W_i > 0$, then industry i increases faster than the whole industry, although the industry i of the whole country is poor, effectiveness of Hubei industry i is better than the whole country, and has competitive advantage. But the effectiveness of the industry structure is relative poor and weak to the whole industry.

4 An Empirical Study and Analysis of Hubei Tourism Structure Benefits

4.1 Empirical studies

This analysis is mainly concentrating not on quality but on quantity. Collecting some data, the author do some quantitative analysis to Hubei tourism structure effectiveness with method of Shift-Share Analysis. Just because of limited data, this article analyzes the effectiveness from the angle of international tourist revenue of Hubei.

The base period is 2004, then we can calculate U_t , V_i , W_i of Hubei tourist departments. As shown in the table:

Table 1 Hubei International Tourism Structure Effectiveness with Method of Shift-Share Analysis in 2010

Department	National foreign exchange composing(Billion dollars)		Hubei foreign exchange composing(Billion dollars)		U_t (%)	V_i (%)	W_i (%)
	2004	2010	2004	2010	2010	2010	2010
Total	257.39	375.46	1.92	2.09	——	——	——
Traffic	77.75	107.81	0.78	0.67	0.46	-0.0721	-0.5277
Shelter	31.24	43.53	0.18	0.12		-0.0653	-0.7267
Catering	19.42	24.51	0.08	0.04		-0.1966	-0.7621
Sight-seeing	13.07	21.3	0.07	0.1		0.1710	-0.2011
Entertainment	18.25	24.19	0.13	0.21		-0.1332	0.2899
shopping	57.98	89.55	0.37	0.4		0.0858	-0.4634
Post and Tele communications	8.81	11.43	0.08	0.07		-0.1613	-0.4224
Others	30.86	53.14	0.23	0.48		0.2633	0.3650

According to the table, we can get four types of the tour industrial structure effectiveness of Hubei:

1) Others departments: $V_i > 0$, $W_i > 0$, it means its structure effectiveness is higher than the average level of the international revenue of the whole country. More over, the increase of these departments received foreign-exchange is faster than international tourism industry. Then its effectiveness is better and has distinct competitive advantage. We can see that others department of Hubei are like this.

2) Traffic, shelter, catering and Post and Telecommunications departments: $V_i < 0$, $W_i < 0$, it means effectiveness of these departments of Hubei are all lower than the average level of the whole country, their increasing of foreign-exchange reception is lower than the average speed of international tourism industry. Then its effectiveness is not only behind to the average level but also behind to the whole tourism industry. These four departments are lack of competitive advantage.

3) Sight-seeing and shopping departments: $V_i > 0$, $W_i < 0$, it means their increasing of foreign-exchange higher than speed level of the whole country, while Hubei are lack of competitive power. This is because of our insufficient advertisements and simple project.

4) Entertainment departments: $V_i < 0$, $W_i > 0$, it means entertainment department foreign-exchange reception is slower than the international tourism industry, and our entertainment is better than the average level. We have competitive advantage to other provinces. But because of the poor effectiveness of the whole country, we are still reduced to absolute inferiority.

4.2 Analysis of the results

According the analysis above, there is a big gap of effectiveness between Hubei and the whole

country. Besides entertainment and other departments, our industry structure effectiveness are all very low, so it's a big vast to adjust and optimize the tourism structure for Hubei international tourist structure effectiveness.

1) Shopping department has weak competitive advantage. Although this department has developed fast these years and brought big profit, we are still lack of advantage to other provinces with development of the whole industry.

2) Shelter department are of low economic benefit, and loss of competitiveness. There are many reasons; the main reason is its runaway scale. Tourist hotel provided too many rooms that exceed market demands. Of course, it reflects our exploiting insufficient markets overseas. This is the main reason of our tourist hotel deficit each year.

3) Catering department has too big scale and low quality that it hasn't complete power. Recently, restaurants and boites are everywhere. Convenient to customers, but low quality. Single dishes, insufficient innovation and quality discrepancy, these are all influence its foreign exchange proportion.

4) Sight-seeing department earns lower foreign exchange than the average level of the department in the whole country. In the circumstance of the department increasing faster than the whole tourism industry, we haven't any competitive power. 3.6% revenue is from sight-seeing department in 2010 international tourist revenue, this data is lower than national average level (which is 5.1%), this is hardly sorts with our sight-seeing tourists. The main reasons are our ageing resorts and insufficient innovation, let alone the worse resorts environment.

5) Long-distance traffic has low structure effectiveness and can't compete with the whole country, which hardly sorts with our convenient location. Long-distance traffic plays an important role in our tourist revenue recently, but reduced to absolute inferiority compared to the whole country. So we must actively improve our traffic.

6) Entertainment department of the whole country is very low, but we have an advantage over the whole country. For the tourism industry, this advantage is disadvantage to other department. For years, tourism products of Hubei are relying on sight-seeing products, while facilities for leisure are exploited insufficiently. Belongs to Participation products, the entertaining products will play much more important role in tourism.

5 Conclusion

Hubei Province of China has obvious advantage with rich tourism resources, convenient transportation and immense developing potential. But we still have obvious shortage such as undeveloped and low industrial structure benefit. So, we must establish the new concept of development, improve competitive power of each department, adjust market structure, develop diversified products, develop and exploit tourist areas well and optimize its surroundings, those are all important things to optimize Hubei tourist structure.

Study on the Construction of Industrial Safety Evaluation Indicator System*

Zhu Jianmin

Economy and management college, Tianjin University of Science & Technology, Tianjin, P.R.China,
300222

(E-mail: jianmin5678@tust.edu.cn)

Abstract: In the open environment, the major factors determining the industrial safety, have been changed, and this article tries to reveal the nature of industrial safety and construct a set of evaluation indicator system in terms of 3 indexes of the first class, the generating capacity of industrial competitiveness, the industrial control, and the supporting capacity of industrial environment, as well as the quantitative analysis of 29 dimensions. And it also endeavors to point out that such factors as the capacity of industrial creation, core technology, and control force are vital to ensure the safety of industry. Firms should constantly update and strengthen themselves in the dynamic management changes, and ensure the industry safety of one country on the whole and in the long run.

Key words: Industrial Security; Evaluation Indicator system; Generating Capacity; Industrial control; Industrial environment

1 Introduction

Industrial security has been the core issue to restrain the economic development of all the developing countries, and the core basis of strategic orientation and policy option of each and every country. For every country, protecting its industrial security is the core to defend the economic safety as well as the country's security. Although China has become an industrial power and its manufacturing international competitiveness has ramped up to some extent, we still need to find that, indeed, this is the case that foreign-funded enterprises contribute a relatively large proportion to Chinese economy, according to the statistic data of China's industrial output. In the background of globalization, international capital flows in larger scale and with a higher speed, bringing redundant capital and mature technologies to developing countries, and simultaneously, allowing developing countries tremendous political risk and economic hazard. There exist many countries which have forfeited their control over crucial industries and core technologies, and in a sense, economic security and industry safety have become the core concern that curbs those nation's economic development.

2 Evaluation Indicator Systems

Follow the design principles of systematization, testability, strategy, and practicability of evaluation indicator system, and then select and ensure the generative capacity indicator of industrial competitiveness, the evaluating indicator of industrial control power and the supporting power of industrial environment to be the first-class indexes of industrial evaluation system. In this way, we then separately select and construct corresponding first-class indexes, basing on that result. Hence, the evaluation indicator system mainly includes the evaluating indicators of industrial competitiveness of industrial competitiveness, the evaluating indicators of industrial control forces and the evaluating indicators of industrial environment supporting power. The generative ability of industrial competitiveness is the essential issue of industrial safety, and the industrial control reflects how much foreign capital influences industrial safety, and the industrial environment is the cornerstone for industry to exist.

Hence, the evaluation indicator system mainly includes the evaluating indicators of industrial competitiveness of industrial competitiveness, the evaluating indicators of industrial control forces and the evaluating indicators of industrial environment supporting power. The generative ability of industrial competitiveness is the essential issue of industrial safety, and the industrial control reflects how much foreign capital influences industrial safety, and the industrial environment is the cornerstone for industry to exist.

3 The Evaluation Indicator System of Generative Capacity of Industrial Competitiveness

(1) Evaluation indicator of generative capacity of industrial competitiveness

Any organization has no access to and has no need to create all the knowledge that it necessitates, and enterprise could absorb knowledge which it needs more economically and quickly through any variety of learning methods. It requires enterprise to enforce its knowledge identification and monitoring capacity, and the capacity to instantaneously track, observe, seek and select new external knowledge, especially tacit knowledge. The capacity to determine the acquisition, conversion and effective utilization of knowledge shall be the enterprise's absorbing capacity, including the value identification, the knowledge acquisition, the knowledge assimilation, the knowledge transfer, and the knowledge utilization.

Absorbing capacity contributes to the formation of innovation, and only if modern enterprises sustainably learn and innovate they can create and maintain this competitive advantage. It has been proven that enterprises with stronger absorbing capacity could present more powerful ability to learn, integrate external information and transform external information into corporate knowledge capital, which makes innovation possible.

The absorbing capacity particularly accents on the corporate awareness, grasp, application and development of external innovative opportunity, and then enterprise will transform them into internal knowledge which could match and coordinate with existing internal knowledge. The stronger the enterprise absorbing capability is, the more powerful the operating capability on external environment is. In the end, it will be more likely to introduce the overflowing knowledge of rivals into the enterprise.

(2) The capability to learn technology

The system of enterprise accumulating knowledge is the source of enterprise's core competencies. The ability of an enterprise's ability to learn, and knowledge translated into action is the ultimate competitive advantage (Jack Welch, 2001). The empirical study of the scholars of organizational learning ability Pilar & Jose(2005) concluded that: "organizational learning capability is the key factor to affect enterprise's innovation". Technology learning is a process to search for and gain useful knowledge from the external knowledge environment, and then digest it, and bring it into the technology orbit or rebuild technology orbit in order to enhance the integral technology capacity of the organization. Technology learning is the inevitable method to form and ramp up the technical ability, and its effectiveness depends on the absorbing capacity of tacit knowledge.

From the perspective of knowledge, the nature of firms to form their own independent innovation is that while improving organizational knowledge stock through social knowledge learning, firms also need strengthen the application of enterprise knowledge to improve the organization's knowledge level, and ultimately turns it into the latent innovation potentials. Bell(1984) systematically conducted a study on the innovation from the social knowledge learning, and he believes that the factors which determine enterprise's innovation is social learning ability, including learning in the operation, learning in the move, learning in the exploration and so on. Rainer,(2005) deemed that enterprise's independent innovation is subject to the constraints of knowledge stock and level, and the independent innovation is the function of enterprise's knowledge stock and level. He stated further that knowledge stock is the initial condition of independent innovation and determine the initial technical capacity as well as the pattern adopted to cultivate independent capability of innovation; the level of knowledge is the requirement to improve the independent innovation, and determine the formation speed of enterprise's innovation capacity. The mechanism between them is illustrated.

(3) Capacity of Human capital supply

The owner of human capital is both the practitioner of innovation as well as initiator of technical progress, and the bearers and disseminators of new technologies. In the Introduction to economic growth, Charles pointed out that: the great differences between human and non-human will lead to inefficient use of resources. The miracles of economic growth in countries of eastern Asia trigger the scholars to transfer their focus from the accumulation of physical capital to human capital accumulation. Human capital is the source of technological innovation and a necessary condition for technology diffusion, and also is an important factor to affect innovation capability, and plays a vital role in the innovation system. Human capital is one of the core elements to enhance the ability of technological innovation, improve industrial competitiveness, increase international competitiveness, acquire technology innovation system, and realize the generative capacity of competitiveness.

In the analysis of labor market human capital for the function of technical, Jacob Ming Seer

pointed out that human capital played a twofold role in the process of economic development: First, a stock generated by education and training skills. It is a production factor, harmonized with physical capital and “primitive” labor in the process of production of total output; Second, a stock of knowledge, it is a source of innovation, and a basic motivation of economic growth. Li Jingwen (1955) thought that, although the company is generally regarded as the actors to produce a source of technological progress, but the labor force, harnessing some knowledge, technology and capacity is the source of technological innovation. Both by self-technological innovation and by learning other’s technology, we still need to invest in physical capital and human capital. We could call upon higher innovative capacity only if we have a large number of scientists of high-tech and innovation. Obviously, human capital is the core element with the most motility; all innovation activities are inseparable from the human capital owners who have certain knowledge and skills. The size of the stock of human capital and the quality structure of human capital has a direct impact on the result of technical innovation. Wang Jinying pointed out that: In general, under certain conditions, the greater the investment in human capital stock, the higher the quality of human capital, and the more the technological innovations achieved. Technological innovation and technological advance have a strong dependent relation on the human capital.

4 The Evaluation Indicator System of Industrial Control

Industrial control theory is an industry safety theory that focuses on the study of foreign industrial control and the control of host industry security. Its core is to emphasize the control of native capital on their own industries, so as to reflect the change of the host industry’s security, but the promotion or demotion that native capital acts upon industrial control is reflected through the study of the strength of foreign capital control on the industry. The basic content of industrial control should contain the control of market, the technical control, the brand control, the control of equity stake of foreign capital. Foreign control or the degree of control could be expressed numerically via relative control rate.

(1) Control of the market. Foreign capital usually controls the host country’s market through acquisition, merger or reorganization and creates monopoly in certain industries, utilizing its comparative advantage in terms of capital, scale, technology, and management. Therefore, the foreign direct investment in the control of the market will affect the host country’s industrial development and the formation of its own complete industrial chain, thus affecting the industry safety. From a certain point of view, the mark of strength which shows the international competitiveness of the country’s industry is the share of a country’s specific industry in the world market, and industrial market share can directly reflect the realization of the international competitiveness of industry. The industry market share contains two indicators ---- the occupancy rate in international market and the rate in domestic market. The occupancy rate in the international market could be expressed by the proportion between host country’s total exports and the world’s total exports, reflecting the proportion of the country in the world export market. Domestic market share is to reflect the situation of the domestic industry’s competitiveness in the domestic market. The greater its share is, the more competitive it is in the domestic market. We could measure through the ratio of the sales of domestic industry in the domestic market and the total sales in domestic. Market concentration shows the economic dominance of a number of the largest enterprises in the specific industry, and it reflects the degree of both economic scale and trade barriers. It reflects the industry indicator of international control from the internal organization of the industry, and you can measure it through the absolute concentration, that is, the ratio of the sales of the largest enterprises within the industry to the total industry sales. Industry chain is a multi-level structure with technical links, which is oriented by the production of a certain kind of end-use products and services, constituted by all the production and services sectors that are interrelated, interdependent, and accompanied with supply and demand relation with each other, formed on the basis of the division of labor and collaboration, and erected through the gradual differentiation of the previously mixed industry procedure under the action of specialized division. If the industrial chain is divorced from the chain of global technology in a long run, there is no doubt that the chain is endangered to be dismembered or marginalized. The endpoints of Industrial chain reflect the absolute control of the industry, and if high-end is monopolized by the foreign enterprises, the development and safety of the industry will be seriously endangered.

(2) Technical control. Technical autonomy reflects that the industry has its own technology which is not dominated by foreign. It can judged by the ratio of the number of invention patents to the amount of the import of technology. Throughout the world, multinational companies integrate and utilize technological resources, control the high-end of technical chains, and dominate the core technology of

important industries, in order to constantly improve the industry's standards of technology and design, and to control industrial development on a global scale. This indicator reflects the survival dependence on foreign technology of domestic industry. It can be measured with the proportion of the output value of introduced technology of the year to the total value of output of that year. If the dependence of one nation's vital industry on foreign technology is very much large, the nation's industry would always linger at the bottom of the industry chain, and the industry development would have to build upon other nations'. The larger the dependence of industry technology on foreign is, the sustainability of international competitiveness will be, the more insecure the industry will be. The advent of the era of knowledge economy makes the world-wide technical standards competition increasingly fierce. The one whose standard is recognized all over the world could reap a huge market and economic interests, fostering the control and competitiveness of the industry. It is the paramount method for multinational companies to control the technology and market that companies dominate the key technology standards of industry and products. Economic benefit depends more on technological innovation and intellectual property rights, and the technical standards gradually become the highest expression of the form pursued by the patented technology. The creation and development of the standards reflects the highest technical level in an industry, and is the authority symbol of the industry. Only in this way could it become the worldwide leader.

(3) Brand control. The higher the owning rate of foreign capital is, the greater the extent of the effects of industrial safety would be. The indicator can be measured with the ratio of the number of total number of foreign brands to the amount of domestic industry brand. Because after the foreign businesses get the controlling position in the joint venture, they would put the brand of the host country enterprises on the shelf and take up their brands, through a variety of methods and means. Brand competitiveness is the outcome of brand competition, is a comprehensive capacity of brands to participate in the market competition, and is a capability erected to occupy markets, achieve dynamic competition advantage and attain a long-term profit because it is hard to be emulated by its rivals. The brand competitiveness mainly reflects in the effect of brand barriers, in the effect of brand market, in the effect of brand extension, and in the effect of brand driving. The brand determines the enterprise's core competitiveness, and is the motive power of the development of enterprises. If the enterprises tend to stand out in the fierce competition, it is necessary to establish an excellent brand, and to improve the brand competitiveness constantly.

(4) Control of foreign equity. The inrush of massive foreign capital will lead to the loss of state-owned assets and national brands; the foreign capital would monopolize the industry by acquisition and merger, or weaken the dominant position of state-owned economy in some industries and weaken the country's economic control through holdings; Usually, the acquisition targets are capital-intensive or technology-intensive enterprises, which mainly occupy the domestic market and only take over the essential part of enterprises, taking advantage of the asset specialty, but leave the negative externality for the society, control the whole at a minimum cost, and mitigate risks. Thereby this would increase the burden on the government and weaken the industrial safety of enterprises. Dependence on foreign capital could be concluded by the ratio of the total amount of foreign capital utilization in one country to the number of the total investment of a country's industry, which reflects the proportion of the industry in the country on the utilization of foreign capital. In the early days when entering into the host country, foreign capital inclines to act as joint venture due to a variety of limits as well as the consideration of their own security, but after a certain period, it will seek the rights of control in the joint venture through a sole proprietorship or a variety of ways, so as to form the equity control of the host country enterprises, and then dominate the host country's industry, thereby reducing the host country's industrial safety.

5 The Evaluation System of Industrial Environment

Industrial Security is an ecosystem, and the domestic living environment is the basis for the survival of the industry. It includes the evaluation of industrial policy, environmental indicators, the evaluation of environmental indicators of industrial finance, and the evaluation of the supports indicator in industrial market.

(1) Industrial policy environment

Marketization and globalization not only have no access to surpassing the national interests, but also can not completely automatically to defend its national interests and industrial safety. The industrial policy is a set of legal or quasi-legislatively binding norms, guidance, behaviors of restriction that the government makes to achieve some particular socio-economic goals according to the main part of the

market economy. In the market economy, industrial policies correct the inherent flaws of the market mechanism, improve the market environment, streamline the resources allocation, and realize the maximum of social welfare in order to carry out the intention of the country, mainly depending on the authority of government resources and guiding role. Under the conditions of sustainable development that depends on introducing technology in a long term and the repression that the advanced countries inhibit the development of developing nations via various ways, the country should transform the structural flaws of industry and technology effectively, and this transformation could not rely on the enterprise's own efforts and the market adjustment forces, but necessitate the corresponding supports of industrial policy and technical policy from the government. It has been proved that only by strengthening the government's macro-control functions in respect of industrial development, we could promote the construction and development of the complete core of the industrial chain through the adjustment mechanism of the fiscal, monetary, tax and other benefits coordination mechanism to promote the construction and development of the complete core of the industrial chain. It could be substituted by the efficiency of the government administration (the Chinese Government Performance Indicators) can be used instead.

(2) Industry financial environment

The survival and development of the industry are inseparable from a sustainable, high-quality capital chain, and then evaluate whether the industry and the industrial and financial environment is safe, through the analysis of the level of capital efficiency of the industrial development and the scale of the capital costs.

(3) The support force of industrial market

The industrial market demand contains the demands of domestic industry market and international industry markets, industry needs. Domestic demand is the prime power of the industrial development, and the greater the demand of the domestic market is, the more beneficial to manufacturers within the industry to pursue economies of scale to reduce costs and accelerate the accumulation of capital will be. Meanwhile, the acceleration of the demand growth of domestic market will also stimulate enterprises to increase the investment and introduce new technologies to further enhance the prime power. It can be judged with the amount of domestic consumption of the year. The demand of international market is to investigate the industrial room for development in the international market. The higher the demand in the international market is, the larger the room for industrial development would be, and the greater the potential of industrial development will also be. Broadly speaking, the industrial demand of international market should refer to the integration of demands of every industrial product from different countries, but as each country has its own corresponding product supply and the competing platforms of foreign products and domestic products are often not the same, thus the industrial demand of international market should remove that part of domestic supply in the short term. Therefore, we should measure the demand of international market, using the total amount of the world's exports of the year.

A Research on Systemic Management of Product Design

Cui Yongying

College of Art & Design, Wuhan University of Technology, Wuhan, P.R.China,430070
(E-mail: 1019016890@qq.com)

Abstract: With the development of science and technology, China's economic structure has changed. For enterprises, the novelty and systematicness for the product design are indispensable which can help the enterprise to survive in the social economic competition environment. At present, many enterprises have used their own program to design the product, which has an important development implication for their systematic management. Therefore, system management is necessary for product design which can guarantee the smooth development for the product design.

Key words: Product design; Systemic; Management

1 Introduction

No matter what the industry is, the form of the product design and development are the same. Each enterprise will formulate the design program of the products according to their own needs. This procedure is not immutable but always changing according to the design needs. The whole process of product design specifications runs through the management function. Essentially speaking, the forming process of design specification is the implementation of management activities which has universality and effectiveness. The design planning and systemic management of the products are equivalent to the strategies and tactics in the war. The former is a holistic concept and the view from the macro point. The latter is a specific method and the view from the micro perspective. However, the two are complementary and indispensable to each other.

2 The Systemic Management in Design Process

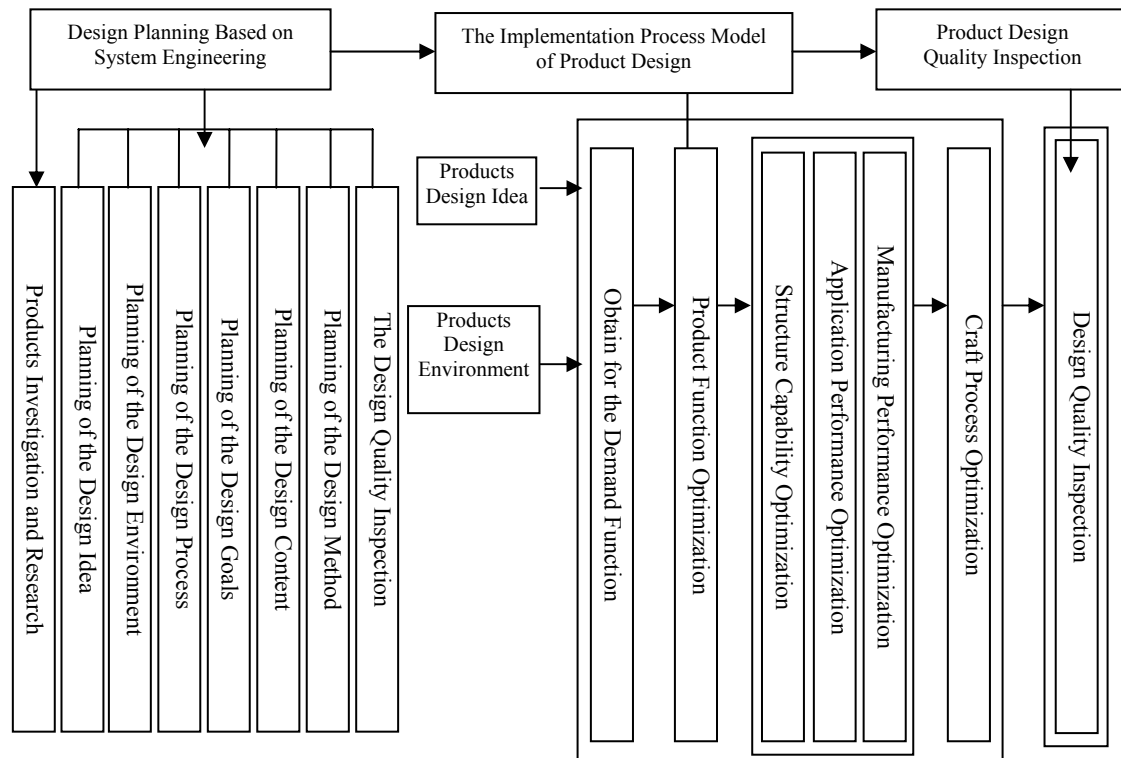

Figure 1 The Design Process Model for Products

The Figure 1 shows that compared with the traditional management method, the process management method has its unique features and regards the enterprise as a process network system

which includes product design, product production, product sale and product quality management, etc. It will optimize the product design process mainly according to the enterprise objectives. At present, with the rapid development of computer technology and network technology, many branches of science and technology have been carried out effective connection. The enterprise management mode is changing. The traditional management mode can not adapt to the development of our society, and there produce a new management mode based on the carrier of network, information, management, etc. When the process management method is applied on the product design process, it will be conducive to improve enterprise's capabilities of processing the information and controlling the situation. Therefore, it is the favor of many enterprises. The product design process on one hand is the embodiment of design specification, on the other hand is the implementation process of management activities. This systemic management runs through every stage in product design. Good results have been achieved by the design process management in practice which is the favor of the design community all over the world. Although their design theories are different, they are trying to enhance and improve all around this process.

3 The Systemic Management in Design Ideology

No matter what kind of the work is, we should have the guiding ideologies. Therefore, the product design is the same. Only by doing product design in the correct guiding ideology can we ensure the quality and performance of products. In the process of product design, insisting on the systemic integrity is the intrinsic requirement of implementing the scientific outlook on development. The systemic management of the product design ideology is mainly reflected in the following aspects: (1) whether the subjective initiative of human can be played and the creativity can be showed; (2) whether the subjective environment and objective environment are in harmony; (3) whether the treatment to the design process is reasonable and comprehensive; (4) whether the final goal is right; (5) whether the technical content is overall and concrete; (6) whether the design method is scientific; (7) whether the final technology results are right. These contents are the main contents of the systemic management in the design ideologies, which have direct relationships with the organization, coordination, and control of the design work and have indirect effects on the coordination, development, stability of product, etc. Please check the Figure 2.

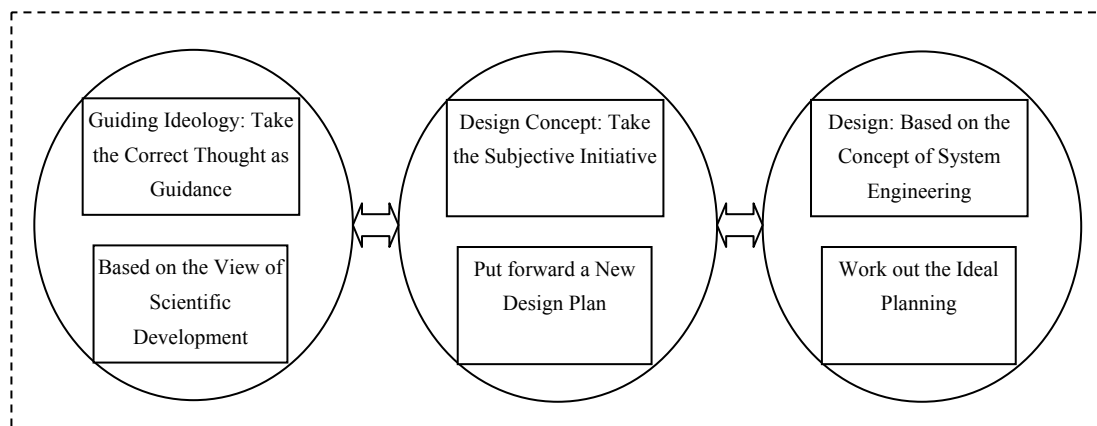

Figure 2 The Design Thought Model for Products

4 The Systemic Management in Design Environment

The thinking of the product design environment is the main inherent requirement of the guiding ideology. In the process of product design, the environment is an important resource which plays a great role in promotion, sales and other aspects of product. Therefore, in the design process of modern product, the systemic management of the environment is very important.

4.1 The social environment and management

The social environment contains a lot of contents such as the politics, economics, cultures, interpersonal laws, environment and so on. We need to focus on the aspects of politics, economics, cultures, laws and others in the systemic management. We must analyze whether the design products are in a state of harmony at home and abroad. If not at the situation, we must try to adjust the harmonious

factors.

4.2 The natural environment and management

The contents of the natural environment which mainly refers to the ecological environment are also in large numbers such as the use of resources, environmental protection etc. Therefore, we advocate the design of green products. When carrying out the natural resources systemic management, it is better for us to control effectively and mainly from the three aspects: firstly, we must make sure that the design products for environmental have no harm. Secondly, we need carry on the environmental design in the product design process. Finally, we must focus on recycling in the use of resources & recycle renewable resources and strictly controlling index in the materials research & development, innovation & use.

5 The Systemic Management in Design Goal

Designers can achieve the desired final state only through the design target which is the main goal of the design work. Therefore, the full considerations of the product design requirements include design idea, design cost, design cycle, design goal and sale service, etc. Although the product requirements are different, the design goals are different also. For the product design, it is not good when the target is too high or too low and this will have adverse effects on the ultimate benefit of the enterprise. So it is necessary for us to carry out systemic management in the product targets. The advantages of carrying on systemic management in the product design targets are mainly in the following aspects:

(1) The management in the design target can make the staff know the enterprise purpose and the enterprise development direction more clearly. The introduction of the target management method in product design process can make the product designers understand the design ideas, contents and goals more clearly so as to ensure that the design work can be carried out smoothly.

(2) The most attention of carrying out the target system management is the result which can promote and improve the planning work of the enterprise better. In the process of product design, the key point of the target management is the design goal. And the aspects of design, content, method will not be paid much attention. Therefore, it can make the product design and planning more perfect.

(3) The target deformity system management can help managers to understand their responsibilities and tasks more clearly, and ensure their functions in the correct position. All those can help them to adjust and deal with the problem in design process in time so as to ensure the design quality.

(4) Carrying out the target systemic management can make the enterprise development direction more clearly. In the design process, adhering to the target management can help us to consider the problems standing in a global perspective. Viewing every problem of design process from the macro level, it helps to ensure the products design quality and improve the market competitiveness of the product.

(5) The main objective of carrying out the systemic management is to ensure that the goal can be realized smoothly. It is conducive for the superior and the subordinate to reach a consensus. It makes the relationship between the upper and the lower more harmonious so as to further improve the working efficiency of the whole work team.

(6) Carrying out the target management can also provide performance reference for managers. On this basis, the managers can do the reasonable evaluation to the performance of the designing product so as to enhance the quality of the products.

(7) The implementation of systemic target management can keep balance between the long-term interests and the short-term profit goals of the enterprise. The target management can start from a global perspective to adjust the goal of the product design reasonable and achieve the balanced development between long-term targets and short-term goals.

6 The Systemic Management in Design Content

For the design contents of the product, we can analyze them starting from the product functions and structures. No matter how complex the product is, it mainly comprises power system, execution system and transmission system, etc. From the view point of design process, it is mainly designed for the function, planning, etc. Due to the different design goals, the design contents are not the same. In design process, we need the systemic management in the design contents which is an important measure to ensure the design safety, effective and reliable and also is the prerequisite to improve the market competitiveness.

The design planning of the product includes a lot of contents which are universal and practical, the design content of the designer. The product design contents are related to the designer, the use of

resources and the design flow, etc. So we need to focus on the management. Look at the following drawing:

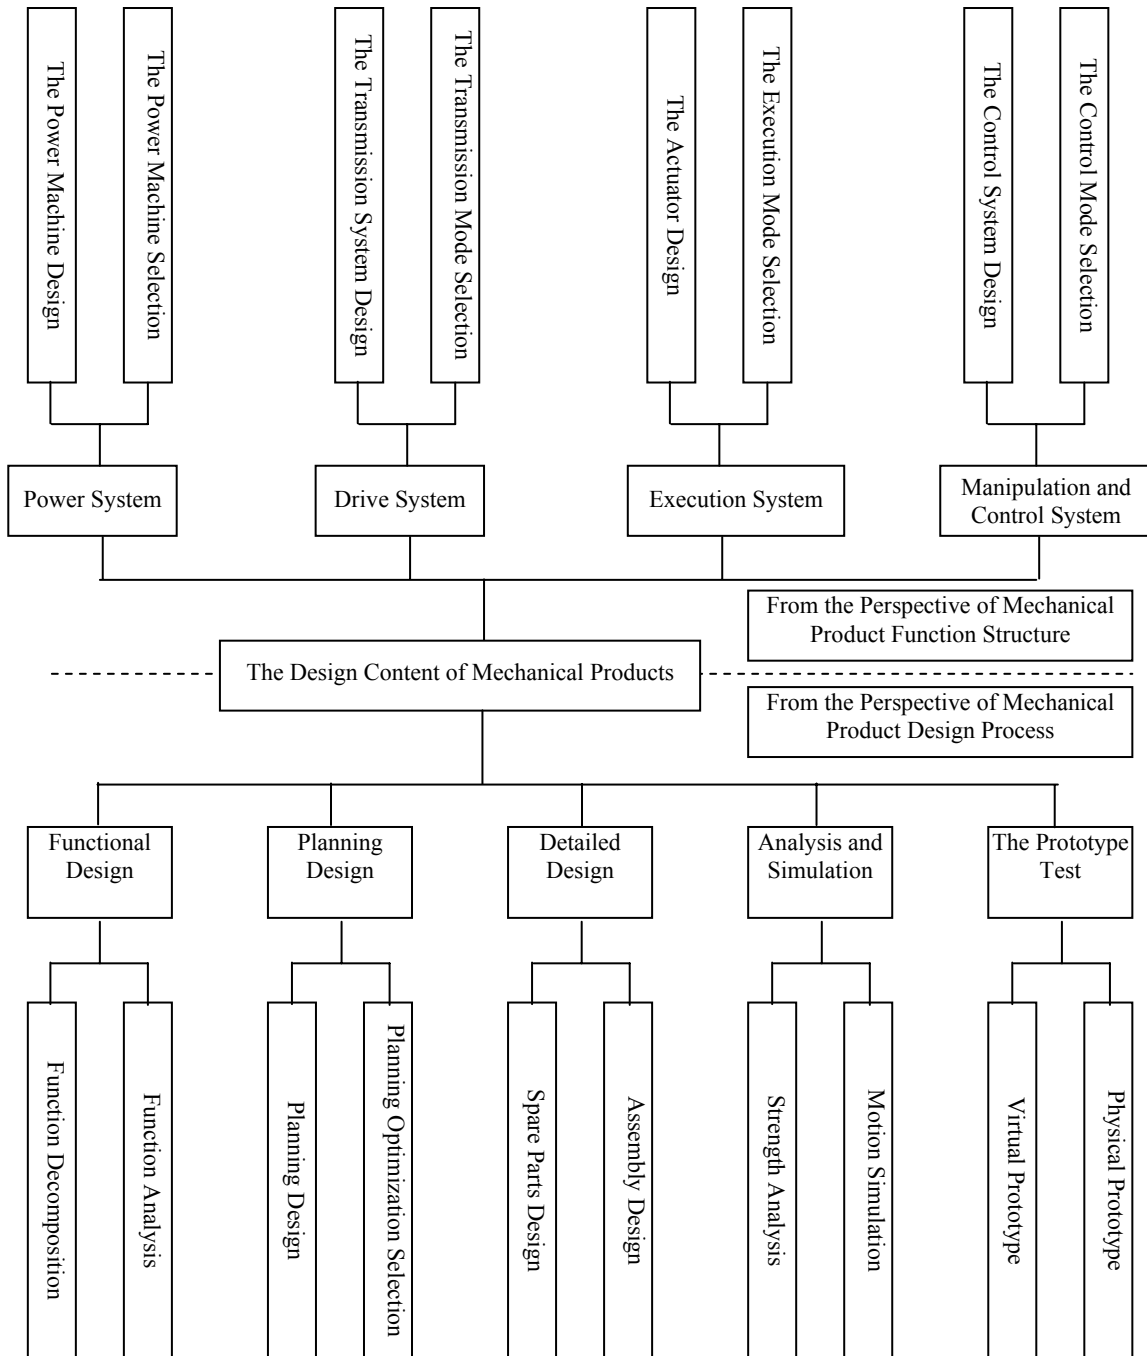

Figure 3 The Design Content Management for Products

7 The Systemic Management in Design Method

The product design not only includes the design ideas, design contents and design goals, but also contains the design methods which are very important. It is the most powerful tool for designers to complete the design work. Design methods are various, Using all the design methods in a product design is clearly impossible. Therefore, we need to select the appropriate design method according to the content and the target of product design so as to ensure that the design work will be completed in time. For the design content and the design target, design method is an important bridge and link. So it is

necessary for us to carry out the systemic management in design methods.

In numerous design methods, comprehensive design method is a method mainly aimed at the function and performance which is very suitable for mechanical equipment, in addition, it has strong adaptability for the large rotating machinery, the transport equipment and the construction machinery, etc. Therefore, in the process of product design, we focus on the comprehensive design method for the systemic management.

8 The Systemic Management in Design Quality Inspection

Quality management mainly refers to engage in some management activities in order to achieve the quality target. The quality management of product design mainly includes several aspects, such as the setting of quality objectives and policy, the quality planning and the quality control, etc.

We can not judge the quality of the products simply from the consumer point of view, but observe from the aspect of production, environmental pollution, ecological harmony and other aspects. It is not only related to the economic benefit but also to the social benefit. Therefore, when establishing the quality objectives, on one hand we consider them as technical indicators, on the other hand take them into account the need of the society. Although the technology is very advanced, the economic problems must be taken into account. Therefore, the product quality management includes many contents such as cost, price, environment and so on. Only by a comprehensive evaluation can we make the products designed reach equilibrium state.

9 Conclusion

Above all, no matter what kind of product is, the quality is the decisive factor of success or failure. The product quality is mainly depended on the product design. Therefore, we should carry out the systemic management in every stage of product design process so as to make the products have strong competitiveness. System management is a kind of quality management method which is a way to solve the interest of the related stakeholders in enterprise. It carries on the management of the ideas, objectives, contents, methods of the product design so as to ensure the quality of the product design.

A Study on the Importance of Business Model Innovation in Strategic Emerging Industries

Wang Zhaojie

Beijing Asia-Pacific Investment Co.Ltd, Beijing,P.R.China,100000

(E-mail: wzj0829@vip.sohu.com)

Abstract: Business models innovation is the key drive force for the development of strategic emerging industries. And strategic emerging industries business model innovation has its distinct characteristics. This paper first puts forwards what a business model is on the basis of previous researches and studies the connotations and features of business models and its innovation; and then it analyses the relationship between strategic emerging industries and business models from four aspects; finally, it expounds and proves in detail that business model innovation is the key drive for strategic emerging industries, and proposes that technological breakthrough and the application of new technology are the foundation of business model innovation.

Key words: Business model innovation; Strategic emerging industries; Technological breakthrough

1 Introduction

The characteristic of the market economy is competition. Famous management guru Peter Drucker said: "The competition between enterprises today is not a competition between products, but a competition between business models."^[12] The emergence of the new economies and the ups and downs of Internet companies have greatly contributed to the deepening of people's understanding of business operation rules. Thereby the enterprise business models get more and more attention. American management expert Gary Hamel (Hamel, 2003) thinks that, in order to create new markets and wealth, managers first need to consider the whole business concept innovation. Business concept or business model is a framework for identifying how the company to be founded, how to sell products and to make profits. Pioneers do not make minor adjustments on the existing business model, but create a brand-new model in an unconventional way.^[8] Harvard University management expert Joan Margarita (Magretta, 2002) believes that a good business model for any successful organization is still an indispensable part, whether it is a new company or an old company. (Konczal, 1975^[4]; Dottore, 1977^[5]) After the rise of e-commerce, a large number of new companies have run their business by means of a way distinct from before.^[1] In order to distinguish between traditional businesses, the term business model has been widely used. Joan Magretta (Magretta, 2002) believes, the term business model was originally derived from the widely used spreadsheet software, which allows planners can easily modify parameters based on different assumptions to obtain a different scheme.^[9] Russell Thomas (2001) defined the business model. He believes that the business model is like running a profitable business which is an overall framework involving the business procedures, customers, suppliers, channels, resources and capabilities. Scholar Magritte • Du Bosen, (2002) and other scholars in University of Lausanne, Switzerland (Lausanne, Université) believe that the business model takes forms as the structure of enterprise and the network of its partners in order to create value, to market the value and offer value for enterprises. It is an asset of customer relationship to make a profit and to maintain the revenue streams. American scholar Larry Bossidy et al (2002) point that business model represents every part of gaining access to wealth, such as profit margins and cash flow; enterprise' relationship with external factors, such as market form, competitive situation and industry trends; and the strategic and organizational skills. Harvard University Assistant Professor Henry Chez Bruce and Richard Rosenblum (2002) argue that cognitive structure of the business model should be developed. They propose that the business model is a framework to reflect the business activities of value creation, Value Offering and value distribution.^[2]

2 Connotations of the Business Model and its Innovation

The business model can be summarized as a logical structure which can make profits itself while the business units are creating value to the customer. It is well exhibited in figure 1 below. Any branch or structural adjustments and changes for creating larger value for customers and expand enterprises own profit margins can be attributed to the scope of business model innovation. Since the late 1990s, the rapid development of information technology has promoted the innovation and practice of the majority of the industry's business model. The individual enterprises in many industries obtained an important

driving force for their sustainable development through making substantive breakthrough in the field of business model innovation. Business model innovation let enterprises shift gears and accelerate; business model innovation is the golden key for enterprises to open the door of “Ali Baba” to wealth; business model innovation is the other shore pursued tirelessly by every enterprise boat sailing in the business sea; business model innovation is an eternal and complex topic. Objectively speaking all enterprises in China have been striving for their business model innovation in different periods and to different extents. Just because of the above explorations and practices, industries in China can develop so rapidly, which exhibits such a lively and fascinating economic scenery.

Figure 1

3 Strategic Emerging Industries and Business Models

Strategic emerging industries reflect the national strategic demands. It combines the new technology and emerging industries closely, and it is a leading industry which has broad market prospects and technological progress ability. The most prominent feature of emerging industries is innovation-driven, breakthrough and guiding. The industries widely adopt advanced production technology, which is in the most centralized area in the scientific and technological innovative production, and in a period of growth stage in the industry life cycle curve. The nature of strategic emerging industries decides it has a complementary and mutually reinforcing relationship with the business model (innovation).

First, a strategic emerging industry needs a suitable business model. The technology roadmap for strategic emerging industries can be undetermined, but the business model is a vital condition for the foundation of the industry, which can be elaborately illustrated below as figure 2 shows. In the first place, technology itself has no economic value. Only when technology is commercialized, can the industry take shape. Even for the mutual technology of emerging industries, business model is of the same importance. In the second place, there exists a severe competition in the technology of emerging industries including various technological competitions within the emerging industry and competitions between alternative technologies with other industries. The increasing research and development costs and the shortening of product life cycle mean that even a more state-of-the-art technology which achieves a satisfactory economic return also need to be commercialized. A good business model is even more important than inspiration and technology itself.

Figure 2

Second, the development of strategic emerging industries is the drive for its business model innovation, as shown in figure 3. It can cause the reconstruction of existing industries, enterprises business model. Technology innovation especially the destructive and radical innovation will inevitably bring a relatively thorough business model innovation, which is the call of the strategic emerging industry’s breakthrough. Nowadays people think commonly that the development of low-carbon industry needs a change of the overall energy industry business model from clean energy products to energy demands of the consumers. The change of this system asks for market application strategy, cheaper and safe and reliable energy products and more appropriate government policies and etc. The studies of Kodama (2004), Yovanof, Hazapis (2008) and other scholars have shown that the technology transformation of industry modulation and industry amalgamation have promoted business model innovation of enterprises in the United States, European countries and Japan, and business model innovation is conducive for enterprises achieve the benefits brought by technological changes in a greater extent [6]. For example, the IBM has implemented the “Wisdom of the Earth” strategy based on the large-data analysis techniques, and divided the strategy into six main systems like hydro, transportation, medical care, social security, safety, education smart city, and intelligent power, energy, business, railway and other areas. IBM undertook thousands of “Wisdom of the Earth” project practices, which have successfully transformed into a business model in intelligent growth.

Figure 3

Third, the globalization of the strategic emerging industries requires business model innovation. A new round of worldwide emerging industry selection, entry and competition have already started after the financial crisis, which means strategic emerging industries' market and production must focus on the global. No doubt new products, new services are demanded in order to meet the needs of people from different countries, and of different living habits, which is the beginning of the business model innovation. It will also cause new changes on the global distribution of industry location, industry chain worldwide.

Fourth, the establishment of the business model is conducive to accelerate the formation of the industrial system of strategic emerging industries and to change the industrial patterns of the existing industry, even to create a new industry. The business model is the source of some strategic emerging industries innovation or itself is an innovative. Business model innovation will create new markets or new opportunities in the old market; it will cause a change on its own as well as its ancillary products and services, and may also produce some new industries, such as the new energy industry, which requires a series of changes on grids, energy services.

4 Conclusion

Strategic emerging industries are based on major technological breakthrough and of the same importance is the industrialization of new technologies to meet the needs of society and achieve their potential economic value; i.e. they must also be feasible in the business field, otherwise it means that they contribute less value to the society and enterprises, and may even be difficult to recover the initial investment in new technologies, and will not develop sustainably. For either existing businesses or new ventures, bringing new technologies to market will be materialized by means of certain business model. The business model is a bridge to connect the technology and its economic value. Technology and market are complex and diverse. They both require being combined to realize the potential economic value of the technology. In some cases, the existing business model can meet the requirements of the new technology; but in other cases, new business models are needed to be created and new technologies rely on business model innovation. A good business model is able to reshape the industrial environment, to stimulate the growth of the industry, and to achieve a win-win situation between enterprises and their industries. Strategic emerging industries business model innovation can help the industrialization of new technology, or can offset the technological disadvantage.

In conclusion, the technological breakthrough is the foundation for the development of strategic emerging industries, but technological research and development is not everything, and the development of strategic emerging industries does not only relies on technology; business model innovation is also the key driver of development of China's strategic emerging industries. A good business model, to some extent, can make up for the technological defects, especially in the case that a large number of enterprises in our country do not possess too much key technology. The importance that business model innovation has not less favorable influence than technology innovation does on the development of strategic emerging industries needs to be attached full attention.

Research Trend of Technology Management

Yoko Ishino

Graduate School of Innovation & Technology Management,
Yamaguchi University, Ube, Japan, 7558611
(E-mail: ishino.y@yamaguchi-u.ac.jp)

Abstract: Many business organizations are eager to continually create innovation and contribute to the society. For this purpose, companies should not only pursue the leading-edge technology but also understand the nature of technology and manage their technological fundamentals to create competitive advantage. Management of Technology (MOT) is a typical research field for this issue. MOT covers many contents including administrative strategy, R&D management, manufacturing management, production control, marketing, accounting, finance, intellectual property strategy, business ethics, and others. By applying a text-mining method to the conference proceedings of IAMOT (International Association for Management of Technology), this study examines the research trends in MOT, detects a change in them that have occurred over time, and finally considers the effects of the social situation on academic research.

Key words: Text Mining; Network Analysis; Technology Management; MOT

1 Introduction

Management of Technology (MOT) is defined as the disciplines of management that enable organizations to manage their technological fundamentals to create competitive advantage. MOT should not only fulfill the management needs of a specific set of technologies within a domain and inter-domain relationship, but it should also develop the implementation strategies according to the available resources, current technologies, future markets, and socio-economic environment^[1]. Therefore, how to manage technology has become an important issue in the past few decades, and the MOT community has developed a wide range of methodologies and applications for both academic research and practical applications^[2,3]. Nowadays, MOT covers a wide range of contents including administrative strategy, R&D management, manufacturing management, production control, marketing, accounting, finance, intellectual property strategy, business ethics, and others. MOT research has been conducted at various levels for each kind of these contents. This made it difficult to understand an overall picture of the MOT research field. Finding research trends, or historically critical topics, in MOT is useful for understanding the key concepts of current MOT.

In this paper, we studied the research trends in MOT by applying a text-mining method to the conference proceedings of IAMOT (International Association for Management of Technology). We detected a change in the research stream and finally found the effects of the social situation on the research trends.

2 Research Objective

There seems to be several methods for investigating research trends in technology management. You might conceive of a method which surveys the trends in papers published in some academic journals. However, since each academic journal has its own predetermined themes, it is difficult to grasp the overall trend of MOT by just reviewing a few journals. Moreover, since research presented in academic journals is already finished, there is a time lag between research run currently and research presented in journals.

Another method to investigate the research trends is to examine the topics presented in major international conferences on MOT. Such conferences are likely to reflect research trends without the time lag found in academic journals, and their proceedings would appear to be an appropriate research target. The problem is how to investigate them. In an international conference, not all presentations are assigned to appropriate sessions, since they are constrained by time and location. In other words, the number of presentations included in a session category does not give an accurate picture of research trends. In addition, the session categories themselves change every year, reflecting the opinions of the program committee.

In light of this situation, this study focuses on the content discussed at an international MOT conference, deliberately ignoring the assigned session categories. We have analyzed the abstract texts in the proceedings of the International Association for Management of Technology (IAMOT) conferences,

in order to find how research trends have changed over time. IAMOT is a non-profit, non-governmental professional association in the USA whose purpose is to encourage high quality research and education in the field of MOT. IAMOT's first international conference was held in 1988, and its 21st conference, which was held in Taiwan in 2012, had approximately 400 participants from 34 countries around the world. The IAMOT conference is one of the most predominant international academic conferences concerning MOT.

The session categories in IAMOT 2003 were as follows.

- Knowledge Management
- Strategic Competencies for Sustainable Development
- Social Impact of Technologies Development
- MOT Education and Research/ Corporate Universities
- Innovation and New Product Development
- National Systems for Technology Development
- Small Businesses and Entrepreneurship/ Technology Incubation
- Emerging and Breakthrough Technologies
- Technology Transfer/ Technology and Security
- Technology Foresight and Forecasting
- Information and Communication Technology Management
- The Integration of Technology and Business Strategies
- R&D Management
- Project Management
- Industrial and Manufacturing Systems Technologies/ Supply Chain Management
- Virtual Organizations and Partnerships/ E-Commerce
- MOT in Developing Countries
- Managing R&D in China

By contrast, the list of the session category in IAMOT 2012 was indicated below.

- Technology-Service Convergence
- MOT in Services
- R&D Management
- Technology Strategy
- Technology Transfer
- Service Innovation
- Logistics and SCM
- Managing Energy Technology
- ICT Management
- Science and Technology Policies
- Science and Technology Incubation and Entrepreneurship
- Science, Technology and Society
- Management of Technology in Developing Country
- MOT Education and Research
- Manufacturing Servitization
- Measurement of Technology
- User Innovation and Open Innovation in East Asia

There is a large difference between the two session category lists.

This study aims to reveal the changes in the MOT research trends by performing text-mining approach on the IAMOT conference proceedings, and to consider the impact of societal changes on academic research.

3 Analysis Methods

3.1 Data used for analysis

For the data to be used in our experiment, we extracted the abstracts from the research papers included in the proceedings of the IAMOT conferences held in 2003, 2008, and 2012. Almost all papers had explicitly the abstract. However, some papers were free from boundaries between the abstract and the body text. In such cases, we determined by hand the text part corresponding to the abstract. During this process, we excluded any papers for which an abstract was clearly omitted.

3.2 Methods

First, we performed morphological analysis on the abstract texts using one of part-of-speech taggers^[4]. Then, focusing on only the nouns (general nouns and proper nouns), we calculated numerical feature values of each noun including the frequency of appearance of a word and the co-occurrence of words. Finally, we investigated the relationships between words using network analysis.

4 Results

4.1 Appearance frequency of words

The numbers of abstracts for each conference year were as follows: 369 in 2003, 236 in 2008, and 207 in 2012—making a total of 812 abstracts in all. There was some variation in the lengths of the abstracts, with the average being 246 words.

Table 1 shows the top 50 ranking words that had high appearance frequency within the 812 files (nouns and proper nouns). We ignored the words “paper,” “study,” “research,” and “result” since these are common to all academic paper abstracts, regardless of the research field. Table 1 shows that the following words that express characteristics of MOT had the highest ranking: “technology,” “process,” “development,” “innovation,” “management,” “product,” and “market.” This result is adequate but insipid, since these words are clearly and directly related to MOT.

Then, we investigated the frequency distribution of the appearance of words. The results show that several dozen words from the top in the appearance frequency recorded very high frequency, while the overwhelming majority of words appeared only a few times.

Table 1 Top 50 Words for Appearance Frequency in Total Abstracts

Ranking	Word (Noun)	Appearance Ratio	Ranking	Word (Noun)	Appearance Ratio
1	technology	51.7	26	datum	19.7
2	process	42.9	27	service	19.3
3	development	41.7	28	literature	19.2
4	innovation	37.6	29	performance	19.0
5	management	34.1	30	country	18.8
6	company	34.0	31	way	18.3
7	product	31.9	32	role	18.0
8	model	31.0	33	resource	17.6
9	industry	29.7	34	environment	17.4
10	market	29.1	35	method	17.4
11	firm	28.2	36	time	17.1
12	business	27.8	37	need	16.7
13	analysis	27.8	38	value	16.5
14	case	27.2	39	R&D	16.5
15	system	27.0	40	issue	16.1
16	strategy	26.5	41	change	16.0
17	knowledge	24.8	42	concept	15.8
18	factor	24.0	43	problem	15.8
19	information	23.2	44	sector	15.8
20	order	23.0	45	impact	15.4
21	approach	22.0	46	use	15.1
22	project	22.0	47	framework	15.1
23	activity	21.4	48	capability	15.0
24	level	21.4	49	policy	14.8
25	organization	21.2	50	effect	14.5

4.2 Co-Occurrence of words

Words can be regarded as compositional units for expressing what an author would like to state. Since the words existing in the same abstract shape together the abstract according to author's aim, such relationships between words are very important. If any two nouns appear in the same abstract, we defined the relationship of them as the co-occurrence. The strength of the co-occurrence can be represented by the number of the abstract in which the co-occurrence is observed. By using a graphical network, we expressed the state of the co-occurrence of words in each conference year. In the network, each word is depicted as a node, and co-occurrence relationships are represented by edges. The edges are drawn when the strength of the co-occurrence exceeds a certain threshold value. We calculated the various feature values of each word network in each conference year, such as the density, degree

centrality, closeness centrality, betweenness centrality, and so on. We found that the feature values are very similar between the word networks of each conference year, since the networks share a similar structure with each other. Moreover, the average distance is short, and the cluster coefficient is high, showing that the networks are small-world networks. Next, we found that the frequency distribution of node degrees (the number of nodes to which a given node is connected) is exponential, and that the networks are scale-free networks. This was observed in every conference year.

4.3 Observed research trends

In investigating changes in research trends, we focused on the betweenness centrality of the network nodes. The betweenness centrality of a node indicates the ratio of the edges between all other pairs of nodes in which that node is included. This metric is proposed based upon the notion that the more routes that pass through a point, the higher its betweenness centrality will be. In this research, the betweenness centrality of a word becomes higher when the word is co-occurrent with more other kinds of words. Table 2 shows the top 20 words for each conference year in terms of the betweenness centrality. What is interesting to note is that in 2012, the word “patent” appeared for the first time, in 8th place. We discuss this point below in greater detail.

First, as shown in Figure 1, we created the co-occurrence network of words in the case of IAMOT 2012, representing the betweenness centrality by the size of the nodes. The large node at the bottom right represents “technology,” and the large node at the top right is “innovation.” These two nodes have extremely high betweenness centrality. However, “patent” (a medium-sized node in the bottom left corner) also has a moderate degree of influence. Next, we investigated how the appearance rate of the word “patent” had changed from one conference year to another. The results showed the following increasing trend: 2.2% in 2003, 6.8% in 2008, and 14.0% in 2012.

There were 29 papers that included the word “patent” in their abstracts in 2012. The majority of these did not include “patent” in the title, and they were spread across the session categories. Moreover, the existing session categories did not have any categories that specialized patent analysis.

The reason why the MOT research that relates to patents increased can be that the progress of the ICT technology permitted enhancement of the data processing ability and development of the patent analysis tools. This might indicate a new and growing trend where people come to use more of the patent analyses in making business strategy.

Table 2 Top 20 Words for Betweenness Centrality

Ranking	in 2003 Conference		in 2008 Conference		in 2012 Conference	
1	technology	0.252	technology	0.216	technology	0.303
2	process	0.206	process	0.120	innovation	0.230

20	sector	0.006	firm	0.009	product	0.005

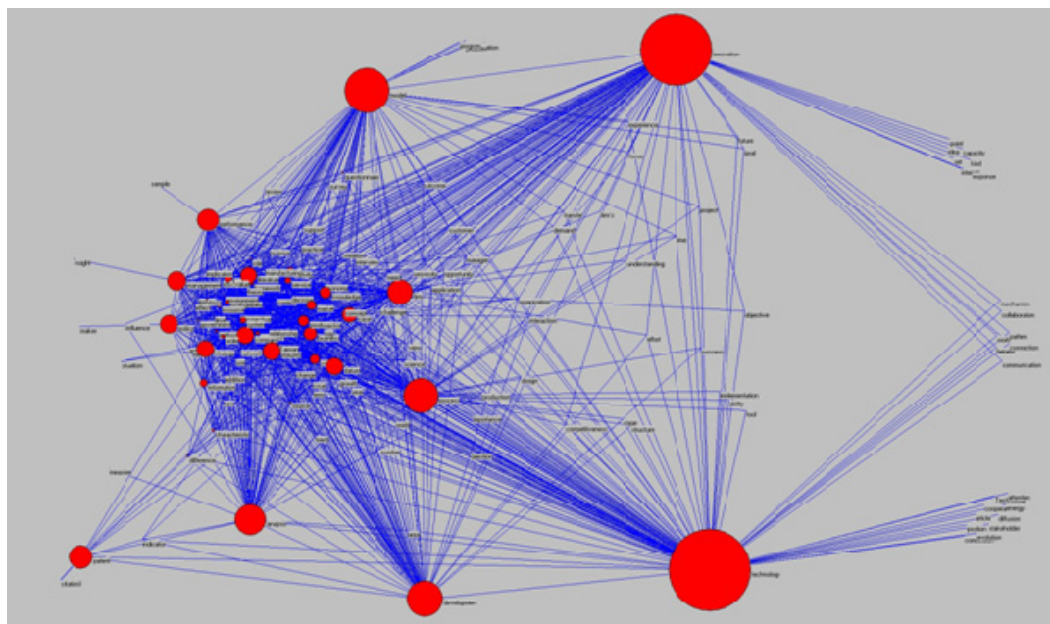

Figure 1 Co-Occurrence Network of Words in 2012 Conference

We have shown, then, that patent-related research has been increasingly presented at the IAMOT conference. We can further say that it would not have been possible to discover this phenomenon from the conference session titles alone. This demonstrates the effectiveness of the proposed method, which combines the text mining approach with the network analysis of the co-occurrence of words.

5 Related Research

5.1 Topic extraction using text mining

Research and development in the field of text mining has increased and spread since the rapid digitalization of text began in the late 1990s^[5]. One field of application for text mining involves topic extraction^[6]. This is the automatic extraction of the appropriate main topics from a group of texts after natural language processing, in order to assist with text sorting. Currently, mechanical topic extraction methods are generally based on a vector space model, in which significant clusters of words that appear in a text are conceived as the base of a feature space, and each text document is treated as a word frequency vector. This study employs concepts that are similar to topic extraction, in which a text is characterized using a vector that represents the appearance or non-appearance of words. However, this study does not select beforehand a set of words that characterizes the topic. A typical research of the topic extraction uses a training dataset where documents for training are already classified into topics before learning^[7]. That is called the supervised learning, whereas this study, by contrast, does not aim to learn the classification of a training set.

5.2 Co-Occurrence network of words

In the framework of a co-occurrence network, words that appear in a document are treated as nodes, and words that appear in proximity to each other are linked by edges. In such a network, words that have a significant degree of relatedness form solid mutual connections called cluster structures. On the other hand, the connections between words with a low degree of relatedness are sparse. Several methods have been proposed for grasping the meanings of words and for eliminating polysemy, by focusing on this characteristic of density of connections in network structure^[8]. Recently, a complex network approach has been used to express the relationships between factors, in an attempt to investigate not only the static characteristics, but also the dynamics of factors. Previous research demonstrated how well the core words of a language (the kernel lexicon) could be extracted based on the difference in the exponential distribution of the co-occurrence network of words^[9]. Another research investigated the difference in the formation of the cluster structure appeared in the co-occurrence network of words in newspaper articles^[10].

6 Conclusion

In this study, we studied the research trends in MOT by applying a text-mining method to the

conference proceedings of IAMOT. By performing the network analysis of the co-occurrence of words, we detected a change in the research stream and finally found the influence of the social situation on the research trends. We have shown that patent-related research has been increased in MOT research. This phenomenon could not be discovered only from the conference session titles.

In the future, we will study the word co-occurrence networks in detail by using new indices representing word features, so that we may find the signs of the research trends. The insights obtained will then be able to be used to create effective educational materials of MOT.

The Complexity Vision for Online Development

Cana Maria Di Grado Hessel, Ivani Catarina Arantes Fazenda
Educational Program – Group of Studies and Research on Inter / Transdisciplinarity
GEPI - Catholic Pontifical University – São Paulo – Brazil
(e-mail: digrado@uol.com.br, jfazenda@uol.com.br)

Abstract: In the perspective of complexity, this Paper is on an experience of online development for school manager, in which an interdisciplinary attitude of partnership emerges. The characteristic of this development is a more complex and systemic vision, in which the school dynamics is regarded as an alive system, liable to be self-organized, a culture in permanent construction nourished by the interpersonal relations and collective work. It values Aesthetical sensibility in development, so fundamental for the projects committed with autonomy and emancipation, despite the fact this kind of Aesthetics has not been valued, but replaced by a more technical form of development. This approach offers the opportunity to experience a historical process, as it evolves contextualized knowledge. School managers and the researcher imbricate in an intersubjective relation while an attitude of interdisciplinary partnership emerges. Interactive online resources are used during the experience in which the narratives unveil the richness of the intersubjective communication and the intrasubjective process of construction and meaning of reality. During the development of this transdisciplinary research, I could perceive the movement of construction of the school managers' own experience, and reflect on my life experience, research my own practice learning about it, while continuously experiencing the two polarities: developing school managers and being developed as such.

Key Words: Complexity; Intersubjectivity; Interdisciplinary; Online development; School management

1 Introduction

There is a big concern on the part of Headmaster or Headmistresses of governmental schools to offer development to the school teachers, so that they can perform organizational changes in the school, aiming at education quality improvement.

Not always are the complaints related to the lack of competencies on the part of the School Manager to manage bureaucracy, but on the low ability in mobilizing the team for the intentional and educative action, conflict mediation, integration between school and community, articulation of personal and collective interests, cooperative atmosphere: in short, actions that require horizontal constructive processes, through communication and intersubjectivity.

Concerning the development of managers, Lück (2000) reveals that the programs of continuous improvement promoted by central organizations of the educational system offer contest which are too abstract for the professionals in development. In addition, they tend to consider the educational issues from a general perspective, distant from the school reality. Other times, the contents, besides not being contextualized, are not stimulating as they have a normative characteristic, once the learner is regarded as someone lacking abilities and competencies.

Thus, the managers in development cannot establish relation between what they study and what they experience. They do not have reference points to connect the contents to reality and construct meaning. The knowledge acquired from personal experience, built with meaning, are not taken into consideration, neither their life stories. The common characteristic of such kind of development is the distance between thinking and doing, two polarities which are not perceived as complementary parts of the same development process.

Proposals for development of managers are expected to be based on the conception of democratic management, social – historical production and the exercise of autonomy. In other words, development recognizing school as culture in process of constant construction, that focuses in processes instead of seeking for immediate results. The emancipatory thinking includes reflection in the development process, both on individual and collective journeys, once the managers can be the protagonists of their practice and development process.

Together with the programs of development with the presence of participants, there have been solutions in the online modality. Programs of development combining both, present participation and online participation have been offered at the federal and state levels, with governmental and private universities.

In this article, a transdisciplinary experience for the development of school managers is described, according to Hessel (2009), as it filters the particular reality through the principles of complexity. The focus is on the construction process of the development attitude of partnership, valuing the process of construction of meanings of the management action, imbricated in the life stories. This attitude of partnership is considered interdisciplinary, as it is an action category, according to the conception by Ivani Fazenda (2006). In this action – development research, we had the opportunity to investigate our practice in the development action, take an intervention and come to relevant learnings.

This development was carried out at national level, by governmental institutions, with the aim to promote continuous improvement of the governmental school managers who are active, for an effective action of leadership and direction of the school community efforts, as a whole, for the achievement of the educational proposals. The project was implemented through a course, in the semi-presential modality, in 5 modules along 4 months, in a total of 100 hours.

Our participation was as a guide /developing professor of a group of 40 school managers of municipal and state schools of a state in Brazil. The action of the managers was followed through communication resources for online work, such as forums and daily narratives. The narratives showed to be an invaluable way to register the development process through intersubjective interactions. The attitude of partnership, on the part of the guide / developing professor, emerged as a way to exercise a guiding and singular action to the participants of the course. Besides containing indications of the peculiarity of each journey, the narratives of the managers conveyed the reflections and the significance of their practice.

Finally, we show the interpretation of the narratives of 3 managers, using the complex thinking references applied to school management.

2 Introduction

The expression School Management was introduced in education to replace the expression School Administration, aiming at encompassing new competencies for the school headmaster or headmistress, in the scenario of re-democratization of the governmental school. The function of the people running a school has been denominated school management to compensate the worn out terminology of administration which is associated to a technicistic interpretation, as well as to incorporate the political intentionality in the educational action. Lück (2000) explains that the difference between the terms is conceptual, once management is a new concept of educational organizations.

School management, in Brazil, is understood as a collective and participative process which runs the school encompassing the actions of decision taking, planning, execution, follow up and evaluation of the educational policy. At the practical level, the manager is expected to take over competencies for the promotion of collective work.

In this way, there will be encouragement for the participation of the subjects of his team and of the school community, assuring the construction and implementation of a pedagogical proposal, that is, a set of intentions, a collective pact.

The strengthening of democratization represents a change in the power network in the school. There is a displacement of axis: the vertical flow of centralized command gives way to more flexible horizontal relations. Power is not crystallized at the hierarchical levels, but it is distributed among the teams of work which assume responsibility for thinking and doing. Decision and action which used to be opposites in the hierarchical pyramid become complementary in the alive dynamics of the balance of polarities. The dichotomy - planning and executing - does not exist in the condition of mutual exclusion.

Protagonism of educators grows, as they share the same ideals among themselves. Their ideals are related to the change of the school reality, and they agree in assuming a common task, defined by negotiation of objectives.

Work plans are not imposed anymore, neither top down nor outside inside, but are rather constructed, implemented and evaluated by the school teams. Democratic management at school, in essence, is not a practice that can simply be established, as it is a self-organizing process, guided by the manager. At the conceptual level, the change of practice seems to make sense. However, at the level of action, the process is not mechanical, as social reality is extremely complex and the educational arena is not neutral.

In order to make this question clear, the discussion on school management will be amplified based on the conception of complex thinking by Morin (2005a, 2005b, 2005c), which encompasses the dialogic movement between linear and systemic thinking.

Linear thinking in management explains the prevalence of hierarchical control and of bureaucracy (bureaucracy). This kind of thinking, a hallmark of our time, tends to simplify reality so that it is understood and controlled. According to Mariotti (2007), it is competent for the treatment of mechanical and functional problems, but inefficient to face questions that require a systemic view. Linear thinking overuses reason, through rationalization, which is immediatistic, simplifying and reducing everything to simple causality.

The traditional model of school management, expression of the linear logic, strictly Cartesian and mechanistic, has its recent origins in the classical theory of administration. The ideas on work organization have the purpose to make business more competitive in the capitalist logic of profit generation and expansion, cost reduction and productivity.

The industrial productive process was rationalized with work division. The aim was to increase the company's efficiency through operational efficiency, that is, rational organization of work. This logic approach is also understood as mechanistic and is a consequence of the linear - binary - Cartesian thinking.

The critical thinkers of the 20th century had an important role in denouncing the alienation present in the productive processes and in the social relations of such administrative models. As a consequence of this alienation, human beings were perversely deprived from understanding the nature and product of their work, as well as from perceiving themselves as human beings, the systemic part of a nature that includes them. The human dimension as a whole was eclipsed by the excessive importance attributed to a fragment of human potentiality, the working-force.

Until nowadays, the characteristic power structure at schools has been pyramidal with fragmentation of school work. As far as school organization is concerned, work division in technical - administrative tasks and pedagogical ones is a consequence of the value given to specialization at work. Functions and assignments are delimited by means of regulations, for the maximization of efficiency and effective hierarchical control. Hessel (2004) explains that, in addition to the horizontal specialization of the position of the school manager, there is the hierarchical aspect in the nets or governmental systems of education. Vertical specialization, also known as line administration, gives the superior in hierarchy formal authority, which is regulatory. The combination of hierarchy and knowledge, putting together the structure of power to the technical or operational one, has been the characteristic of the model - pyramidal structure at governmental schools.

While linear thinking is efficient for the analysis of the parts of the whole, systemic thinking is important for the understanding of the interdependence of the parts. This kind of thinking is necessary for the manager, as it allows him to visualize school life beyond the bureaucratic routine and formal functional relations.

In Capra's view (1997), systemic thinking is a contextual kind of thinking, as this is its own essence. A system is a group of elements which are correlated. They maintain a form of organization and structure. The organization defines the identity of the system and expresses its configuration by the essential characteristics of its parts. The structure is defined by the relationship of the parts. The structure of a system changes during its existence, in continuous exchange of energy with the environment.

Work organizations can be conceived as dynamic nets, not linear ones, once the mechanistic paradigm is not enough to explain them. For Capra (2002), human organizations are like living systems. They cannot be controlled like machines, through instructions as they react to impositions. A machine can be operated with efficiency because its control is predictable. When it is broken it cannot change by itself and depends on maintenance. For example, a change projected by the administration and imposed to the organization tends to generate bureaucratic rigidity.

Considering an organization as a living being, we see the system is able to get self-organized, learn, change and naturally evolve, as its intrinsic characteristic is self-production. It is in permanent retroactive, circular movement of self-creation seeking for sustainability in the balance of two paradoxical forces: autonomy and dependence. However, it can create its own identity with its characteristic culture, understood as a set of meanings shared by the subjects in a historical dimension. That is how the emancipatory process is experienced.

Complex thinking encompasses linear thinking expressed in the bureaucratic matrix, as well as systemic thinking whose characteristic is the view of the whole. Both are dialogically opposites, that is, complementary opposites, according to the conception of complexity by Morin (2005a, 2005b, 2005c). Linear and systematic thinking are always present in the same reality. Prevalence of one over the other

may represent an attitude of simplification in reading reality, if there is excess, for example, in particularization or generalization.

School organization reflects, in its own extend, all social complexity, as it is a cell of the social hologram and expresses the dynamics of the whole of which it is part. Like society, it is also a living organism which gets self-organized. In itself, the relations are ambiguous, being complementary and antagonic. Together with the movements of change, there are conservative forces, collaboration and resistance, order and disorder. Routine and emerging situations alternate, formal and informal relations flow in parallel, conflicts and ambiguity are natural in the game of convergences and divergences. One force always operates as an answer to the simplifying character of the opposite force.

A big challenge for the school manager is to embrace the coordination of bureaucratic activities and pedagogical ones in such a way to express a relation of interdependence. In practice, there is a division of tasks: the pedagogical activities tend to be under the supervision and total responsibility of the pedagogical coordinators, whereas the bureaucratic ones take all the time of the school manager. This scission is a consequence of a fragmented, reductionist view of the school teams.

Thus, they base their actions exclusively in the assignments defined by the school regulations. What lacks is the view of the whole, perception of a systemic reality.

The pedagogic and bureaucratic tasks are imbricated in the democratic dimension and in complexity. The bureaucratic tasks are necessary to give support to the everyday life at school, as well as structure maintenance, project implementation, in others words, to vivify the purpose of the formative pedagogical process. Otherwise, it can be only linear and instrumental.

Besides the bureaucratic and routine activities, there are the planned actions. The first are predictable and remind us of rigidity, the others deal with uncertainties and the elements that emerge. According to Morin (2001), planning is a more strategic action, as it deals with unpredictability and flexibility, in opposition to a program where everything is done automatically.

Planning, in the complex and democratic dimension, is an action that depends on the participative movements. They emerge and are consolidated as the leaders and those who are leaded do not take position of excluded opposites. Management, in this case, is not exercised with authoritarianism, but rather, by gaining recognition and legitimation when there is respect and value to individuality and diversity. Balance between the polarities is maintained because the focus of changes remains in the interests and meanings. Significant disturbances act naturally in the organization, perceived as self-organizing systems, without the need of making a mechanical effort to keep them moving.

In modern organization, communication of intersubjective nature emerges in the core of the managerial practices, as there is a decrease in subordination relations and transmittion of orders and directions. Interpersonal relations based on authoritarianism, obedience, vigilance and control are evaluated again and get new meanings in the model of partnership and collaboration.

3 Online Development

For the semi-presential course for government school managers' development, in which we were in charge of the development, there were individual and groups activities for learning in action, in a reflective and shared way. The dynamics adopted was reflection on the practice, articulated with the theories related to school management.

From the beginning, the school managers were asked to mobilize their teams of educators for the elaboration of an intervention strategic plan in the specific school realities, starting from a diagnostic evaluation of the school dimension, as for example: the school environment pedagogical practice, evaluation practice, democratic management access, students permanence, etc.

The communication resources, daily narratives and forum, had an important role in the support of intersubjectivity, integrating the participants of the course, debates on theory and practice, exchange of experience, and follow up of activities. The use of daily narratives allowed us to have a reserved contact with each of the managers. This communicative privacy was assured, and the participants knew that their narratives would be read and commented only by the professor guiding the development course..

In this development, the daily narrative were projected to catch, in the written registration, the impressions of the managers in the form of reflection on the own personal evolution process, as well as participation in the course.

By using this virtual resource, we understood from the beginning that we could follow processual aspects in the development of each manager, mainly those related to their feelings, intentions and meanings. The daily narratives were perceived as instruments of intrasubjective reflection and

intersubjective exchange, in which The attitude of partnership could be developed, in the form of guided messages.

The interdisciplinary attitude of partnership experienced during the development process of the managers emerged out of the value attributed to intersubjective exchange in daily narratives, based on the respect and recognition of the manager as an autopoietic being, who is product and producer of his/her development and builds his being and doing recursively through the interaction with the others and the environment.

The concept of autopoiesis described by Maturana & Varela (1997) is the basis for this thinking. Every living creature is a living system, open and in constant exchange with the environment. He or she is paradoxically dependent and autonomous. Dependence on the environment in which one lives, as a result of the need to creatively get adapted in order to survive there, although not being determined by it. The environment only starts a series of structural changes in the living system, without directing them.

Autonomy comes with the ability the being has to get organized, in continuous cycles, that is, in cognitive interactions which are recurrent. Learning takes place so that the being can survive in the environment, changing the structure, but keeping stability in the inner pattern of organization. Thus, a living being cannot be controlled, just perturbed. Changes do not happen by imposition, but from inside out.

Our action for development was meant to grasp to context of the manager in development, understand it by means of the complex view and act in the congruence between both, the professional in charge of the development and the manager, using messages which guided for the consolidation of a democratic management practice. No formulae or immediate solutions were used from the linear thinking. The comments on the narratives of the participants were short and expressive, once we agree with Capra (2002) that they constitute 'significant forms to perturb the process'. In such cases, significant impulses are more pertinent than prescriptions of routes of instructions.

All the narratives were treated as parts of life stories and were read through the filter of complexity: moving between the whole and the parts, perceiving how the parts are related. It would make no sense to compare the narratives to make generalizations, as, according to Dominicé (1988, p.147), each narrative reflects the way the journey was understood, the development defined and the process interpreted.

We were based in Fazenda's methodology (2005, 2006), considering that each one has a particular way of doing things and has to be recognized in the singular dimension, contextualized and imbricated in a life story. And, just as Josso (2004), we understand development as a process of self-development, when the subject becomes conscious of him/herself through of intersubjective approach. When we valued the narrative as a reference bringing knowledge of the self, we recognized the singularity of the development processes which have the power to transform "[...] life programmed in a social cultural way into a master piece to be built, guided by an increase of lucidity [...]" (p.58)

We could perceive, in each narrative, the sense of a practice. As an ontological process, the narrative contains a peculiar perception of the reality, focused from a universe of belief built from experiences and values. It reveals a way of thinking and feeling the world, in which the subject perceives him/herself - a personal word. It is a means to produce meaning, as the experiences are composed of content and of a narrative artifice which shows a singular characteristic in its subtle shades. Different from speech, in which simultaneity of speech and thinking makes reflection difficult, the meaningful written registration is a secondary discourse which mobilizes thinking and rethinking of the object in question. According to Sabbag (2005), when the subject narrates facts which were experienced, he/she rebuilds his/her representation of reality bringing new meaning that can transform reality itself. Thus, one becomes conscious of the singular process of construction of identity, as people build differentiated meanings during life. This eternal self-construction and reconstruction of the being, in connection with the others, is the way to build individuality, autonomy and emancipation.

Fazenda (2003) stresses the importance of the narratives of experiences, as they are possibilities of innovation and interdisciplinary analysis, once they can generate new prospects. They are an opportunity to experience a new dialectic and contradictory movement, as they use both, registration and memory, for a new critical reading of the facts that had taken place. New meanings are constructed by the dialogic movement of the old and the new.

4 Revelations of the Narratives

We chose to use an interpretative analysis to understand each narrative in order to make explicit both, form and meaning. For this purpose, we used the universal elements to treat the realities narrated

by Bruner (2001): narratives always have a central problem; action narratives contain states of intention; the understanding of the narrative is hermeneutic; there is a structure of consigned time in the narrative; there is also historical extensibility in each narrative.

We selected three narratives considering: the willingness of the authors to write them, besides the minimum expected quantity of narratives, that is, at the end of each of the 5 modules; and the willingness of the authors to register their reflections. To identify them we used fictitious names: Leila, Celia and Selma

Leila's narratives reveal her efforts to overcome the linear vision in the school reality. All her narratives are permeated by a strong feeling of fear in relation to the course, to the technology adopted, to the modality – semi-presential, and to the demands of work to be implemented in the school.

The conducting line or the central problem in all the narratives is the lack of confidence that makes her dependent to take any decisions. There is a belief that the difficulties found are because of material restrictions and people's lack of availability.

The narrative shows that Leila does not regard the school as a culture in construction, in which interests are shared, as well as latent meanings and history.

There are no indications of collective work based on communication and intersubjectivity. She lacks vision for the systemic thinking and the perception that she has the power to mobilize the team for participation, co-responsibility and autonomy.

The structure of time of the narratives informs that they were produced in relevant moments, showing the change of direction in the course or in the school. At a given point, her lack of confidence was countered with sharing experiences, both virtual and presential. In the process, we guided Leila to the forums, where she can meet interlocutors willing to debate and share such problems. She feels reinvigorated, with her enthusiasm reestablished and she takes action at school and finds a way to create complicity among the members of her team.

With the knowledge she got in the course, she could implement evaluation processes, intervention actions, follow up and control, necessary to the administrative practice. However, the strategic meaning of such competencies could not be characterized as linear and mechanic, but rather, as a contextualized political action to be experienced, based in the understanding of the intersubjective nature of the participative practice.

Leila has difficulties that result from her linear view of management. There is a way to be covered by her and her team to overcome work fragmentation and adopt more participative practices. It is necessary to regularly experience processes of evaluation and become responsible for their actions. Communication channels must be opened through willingness to listen, share, exchange, etc. Relationships based on trust must emerge to sustain collective actions. Besides the technical knowledge, the social competence must be learned by the manageress.

Our partnership action helped the manageress give the first steps in the new direction. Whenever possible, she was encouraged to take part of forums, in order to enjoy the sharing of experiences.

As for Celia, her narratives reveal her systemic perception of the culture. The content of all her narratives shows that there is a central axis, around which all the narrative is developed, that is, the concern to get the participation of the school community. It was possible to grasp that, while reading all her narratives. In each one, Celia develops an only story of difficulty, hope, overcoming and success. In all the parts, the plot is repeated in cycles and the manageress renews her willingness to take new actions. The parts are contained in the whole.

Celia values human relations, rather than the vision of the functional tasks of the teachers. There is commitment with the construction of the school culture in friendly and affective levels, which minimize isolation and fragmentation of the school work.

She realizes that democratic management consists on the mediation of intersubjective relations and is attentive to the participation of all the sectors.

Her narratives assume a unique identity. She establishes an affective relation with her narratives calling them: 'My dear diary!', as well as by greeting them: 'My diary, good morning!' She feels comfortable to write and can express feelings and subjectivity.

Celia has a systemic perception of the collective work. She knows how important the participation of all the segments is, in the school projects. Her practice is built by overcoming challenges. In difficult circumstances, she tries some hypothesis and, strategically, finds ways to mobilize parents and educators, to be co-responsible for the educational action. Her purpose has being the involvement of the subjects assuring more commitment. In the online development, she learned the theory on plans, and felt the

need to validate her practice and beliefs, through her narratives and affective identification with her narratives.

For this reason, our action of partnership emphasized revisiting her messages on the feedback about the way she guides her work.

As for Selma's narratives, they reveal she regards school management in a complex way. She produced 12 narratives in journalistic style. The time structure in her narratives shows that the significant elements mentioned are close to the episodes of the course development, as they were built along the course. It is only from the history of the meetings with other managers that the protagonist finds reasons to speak and reflects about her school.

There is a transversal axis in Selma's narratives. The centrality of the whole is on the principles of collaboration and sharing, and her belief is that one can only learn with the other, listening and sharing. This essence which is found in each narrative, in each part of the whole, is the point of her narratives, as well as the motivation for her practice which unfolds in partnership attitudes. That suggests that the concern with her peers, in this moment, is her biggest concern.

Selma's considerations reveal a good understanding on the self-organizing process. She emphasizes the importance of collective work and ponders about the difficulties in developing it. By experience, she knows it is fundamental and that it has to be built through the dialogic movement: giving and receiving contributions. She understands ambiguity and the paradoxes of everyday reality at school, as she is conscious that facing them is a process, and she knows that it is possible to work with plans' linearity, as well as with the emerging elements from uncertainties. She understands herself and the others as autopoietic beings, able of learning in all the circumstances of life, both in professional practice and development periods.

Selma shows mastery in the conceptions on democratic management which seems to come from theoretical and practical reflections. She values collaborative learning and always comments on the importance of the moments of intersubjective sharing. In the narratives, she reveals the work dynamics of the school where she works, that is, the involvement of all the segments in the actions diagnosed and in action plans. Mobilization, co-responsibility and commitment on the part of the school team are indications that the experience on democratic practice is a reality, and that decision and action are imbricated in the field of collective work.

Our messages to Selma were invitations to play the role of an advanced peer and bring her contributions in the forums, with her experience and suggestions, once she enriched the course, when she shared her ideas on collaborative learning.

5 Conclusions

The transdisciplinary treatment of the reality in this research made it possible to reveal the procedural imbrication of the actors of the formative context.

The attitudes of partnership and respect to the formative journey of the school managers emerged with intention in the narratives, in the interlocution between the professor in charge of the development and the people in development. As we felt identified with the managers in development, we tried to establish, in a subtle way, the attitude of listening, friendship, without showing absolute truth, nor privileged knowledge.

In the basis of this intentional action, stands the belief that the manager must reflect on his/her doing for new meaning and construction of the organization action, articulation and mobilization in the political context of the school, in connection with the community. It is a creative process, taking the environment into consideration, which encompasses *in Moraes' words (2004, p.141) 'cooperation process, eco-construction and coevolution'*.

The attitude of partnership flows in the context, and that is why there is no fixed route in the dialogue between people of different journeys. There is a creative movement which is established in the congruence between the professor in charge of the development and the manager in development, which is revealed in the action based on respect and the ability to wait, as according to Fazenda (2003) it is by waiting that we can find the best moment for an intervention – an interdisciplinary principle.

It is an action whose movement is not reduced to the linear relation of cause and effect. It has a constructive character through interactions welcoming sharing. It is fed by retroactions, which act in return to the process which produced them.

The role of such retroactions is fundamental, as it may determine, inhibit, accentuates, change and transform the actions and interactions (MORIN, 2005a).

The interpretation of the narratives of the 3 school managers revealed the different moments experienced by each author, as well as our interdisciplinary attitude of partnership. We tried to reduce the feeling of lack of confidence and sensation of isolation experienced by Leila. As for Celia, we used massages of guidance, with the intention to help her understand her practice. The attitude adopted with Selma was that to try and consolidate her posture of partnership with the other managers.

The formative potential of the narratives, which initially showed as a tool adequate for intrasubjective reflection and intersubjective exchange, gained relevance as it allowed following the development process online. By following each manager, we could identify the way of their journeys, their strengths, needs, fears, the reflexive processes of re-elaboration of the experience.

In the interpretation of each narrative, we observed that they reveal, besides the different journeys, the essence of their authors. There is truly sense in all the doing, which is not at random, but built along life. By encouraging the written registration in the narratives, the professor in charge of the development can help the subject in development be conscious of his/her doing, rethink action and change posture, using the references and conceptions on management. In the online development, the written registration of the personal narratives has to be valued in the proposals for change of praxis, as it represents the possibility of taking care of an ethical and aesthetic knowledge, that is, of the soul of the technical knowledge.

A manager's development cannot lose sight of the manager as the subject of the development, his/her practice, vision of school reality and conceptions on management. At work, he feels challenged to mobilize the team to experience the democratic process, once the prevailing thinking at school is for reduction ideas, which fragment reality. In such conditions, power relations are kept hierarchical and bureaucratic aspects prevail on a more systemic view in which school is regarded as a living and self-organizing system fed by interpersonal relations. To deal with the contradictions of everyday life, it is necessary to have the view of complexity on the school organization, as management has to deal with predictability and uncertainty, too. Complexity encompasses the dialogic game of linear and systemic thinking.

We believe this research may contribute for the public institutions to reconsider their development models, which often follow the instrumental development model, in detriment of the Ethic Aesthetic development.

Abstract: The research carried out to identify ways in which tools and methodologies from Theory of Inventive Problem-Solving (TRIZ) to solving gaps within the Design-To-Cost (DTC) strategy in product concept development. The aim was to develop an implementation framework for DTC improving product cost and at the same time increase the product innovation. The research paper reviews TRIZ methodology that has potential to be applied for cost reduction initiatives, followed by a discussion of the DTC strategies that commonly practiced in the various industries. The proposed new DTC implementation framework with TRIZ tools is developed and the research paper concludes with a case study using the new DTC Framework.

Key words: Design-to-Cost, Cost Reduction Strategy; Inventive Problem Solving Technique; TRIZ Tools

1 Introduction

Market liberalization and global competition push companies to change the way they run the business. Automotive companies have to juggle between meeting the customer requirement, time-to-market and most importantly the investment cost, the main risk in product development project^{[1],[2]}.

Some firms adopting DTC strategy to provide solutions to these challenges. The DTC strategy always has been combining with target costing as the foundation of cost management in product development project. The DTC provide opportunity of early involvement for engineers or designers to create product that meet the target cost which have been derived from target selling price and target profit. DTC is a method of 'Management by Objective', step by step design uses the information of difference^[3]. However, in real situation, a lot of product development projects have been dragged backward or delaying the time-to-market, resulting in huge negative impact to the organization goals. Some DTC ideas have contradiction parameters between low-cost product design and quality performances, conveniently trade-off has been used on conflicting requirements and accepted as the solution to the design. The trade-off analysis will provide solution that needs an amount of sacrifice in customer satisfaction to achieve a certain amount of cost saving, this will negatively impact the product competitive performance and hence product innovation.

The analysis on DTC framework done by Williamson^[4] pointed out that to apply the strategy without strong justification brings failure to the cost reduction effort. Trade-off in design constraints, will hinder the effort to explore the ideas towards more cost reduction and halt the product innovation growth. Trade-off in DTC may change the direction of product development^[5], thus drastically affect the project goals.

This paper presents the application of TRIZ tools in DTC implementation to resolve conflicting parameters in product concept design and development without any trade-off.

2 Literature Review

2.1 Design-to-cost implementation

In facing today's turbulent market environment, companies are compelled to integrate and synchronize product design, process planning and cost estimating activities rather than following sequential planning procedures. Product and process modifications are more expensive at the later stage of product development cycle. The objective of concurrent cost information is to optimize the product design with respect to balancing the trades-off between cost and performance requirements before the prototype is built. The identification of cost and performance sensitive parameters to forecast the system's competitiveness is still being developed.

DTC methodology evaluates the cost and performance of a design solution in a top down approach, i.e. the evaluation of a system design instead of a single component design. New technologies can alter the component manufacturing as well as its assembly methods without changing the entire system.

Taking this into account, competing system designs have to be compared at the system level. As a result, the cost model has to evaluate and aggregate costs from lower to upper system levels. One way that companies can regain control over their costs is through systematically classify and identify product costs. Using a systematic approach to perform cost reduction not only yields cost improvement but provides decision-makers with the trades-off involved in achieving these reductions [5].

The strength of DTC is the capability to define a measurable design parameters against performance, to bridge the communication gap between designers and others in product cost reduction, the capability to improve total cost including product and the processes and focusing on idea generation to reduce product cost. DTC also poses some weaknesses, such as resorting to trades-off to quickly solve any issue of unmet target cost, low innovation in product design, not improving deficiencies in critical areas or any harmful functions, indirect implication such as delaying the project time-to-market and impact the development cost [6].

DTC concept has a long history of use in the U.S. Department of Defence for evaluating new weapons system. This directive defines DTC as “a management concept when vigorous cost goals are established during development, and the control of systems costs (acquisition, operating and support). Practical trade-offs are often made between operational capability, performance, cost, and schedule. Non-defense related industries also apply this concept to their major procurement decisions. However, often in both defence and private sectors the cost goals are not achieved due to lack of proper planning and control of management tasks at different stages of the product life-cycle.

Table 1 show that the application of DTC started in the military and aviation sector later expand to non military industries. It also shows that the more case studies using target costing and design to cost is the automotive industries. Adopting DTC and target costing is significant to the automotive industry due to the level of product complexity that needs to be managed, similarly with the aeronautic and aviation industries. Free Trades Agreement create competitive environment for the manufacturer to increase their market sales and generating higher profit by producing low product cost with better quality [20][23].

In a manufacturing environment, the tools used in DTC strategy to generate ideas and in problem solving process are limited and not systematically structured [11].

2.2 Current knowledge of DTC framework

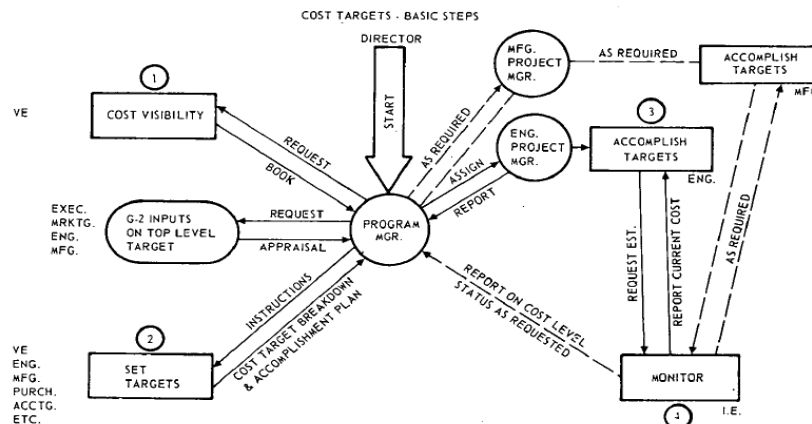

Figure 1 DTC Implementation Framework by Steinmetz [22]

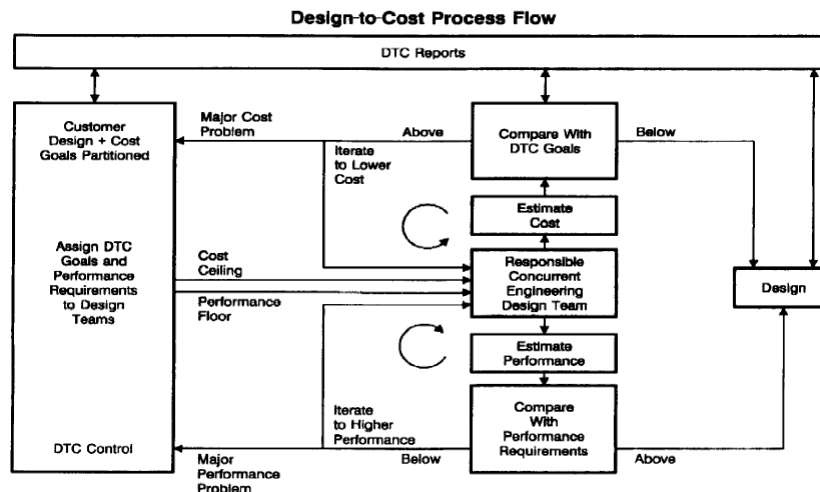

Figure 2 DTC Implementation Framework by Williamson ^[2]

Similar point highlighted by Williamson ^[4] that DTC need to start as early as possible in order to identify the opportunity to make improvement easier and maximize the cost reduction and other benefit, as shown in Figure 2.

3 Integration of Triz into DTC Strategy

TRIZ, a Russian phrase “*teorija rezhenija izobretatelskih zadach*”, means the “theory of inventive problem solving” ^[25]. It was developed by Genrich Altshuller (a Russian scientist and engineer, 1926-1998), who studied about 400,000 technology patents¹, and from them drew out certain regularities and basic patterns which governed the process of solving engineering problems, creating new ideas and innovation. This provided an understanding for the creation of a systematic process for invention of new systems and the refinement of existing ones.

Implementing the concept of DTC in the product design, is essentially decision-making exercises. Earlier analytical tools were unable to secure the issue of uncertainty in decision making process. The main issue is that the effect of decreasing one or more key factors, simultaneously increasing one or more other key factors in design projects ^[26]. The emphasis on ‘trade-off’ solutions in traditional problem solving practice often means that designers are rarely explicitly aware that conflicts exist. Therefore it can be conclude that the need of new approach is critical in decision-making activities, which eliminate the dependability of trade-off concept.

Engineering Contradiction principle in TRIZ is the need for problem solvers to actively seek out the conflicts and contradictions inherent in all systems. The following TRIZ methodology is trying to ‘eliminate’ those contradictions rather than to accept them. By solving contradiction and strive towards ‘Ideality’ without any trade-off. Therefore, TRIZ have the capability to provide the opportunity to complement the significant weakness in adopting DTC concept in product design, even though there are constraints for TRIZ tools be used in cost improvement activities ^[27]. There is also time/cost trade-off or contradiction for innovation, when development time is shortened, cost is increased. The core of innovation is to find difficult problems, such as the problems with contradictions, and to solve them quickly. TRIZ is expected to provide solutions for the restriction of innovation and technology improvement experienced in implementing DTC in product design and development, such as upgrading value of design ^[28]. Designers who adopted TRIZ will increase the speed of product development and reduce the cost at same time.

TRIZ method has begun to be integrated with a number of established and emerging problem definition and problem solving tools and strategies. This integration of TRIZ have been achieved with other concepts such as Quality Function Deployment (QFD), Failure Mode Effect Analysis (FMEA), Value Stream Mapping (VSM), Value Engineering (VE), Theory of Constraint (TOC), Taguchi, Design For Manufacturing Assembly (DFMA), Six Sigma and other established new integration concept ^[29].

Based from the summary in Table 2, the main TRIZ tools that are suitable for DTC are product & component analysis, function analysis and trimming. Then from the trimming activity, a problem is normally created to solve function problem or contradiction problems between parameters. The DTC

ideas that are generated from TRIZ tools need to be reviewed and evaluated. In evaluation phase, the idea will be rated based on two contradicted criteria, ‘Ease of implementation’ and ‘High potential cost saving’. Using the Contradiction Matrix, both parameters associated with the criteria provide general solution to solve those contradictions.

Table 2 Literatures on DTC-TRIZ Integration & Applications

No	Authors & Year of publication	DTC gaps	Cost reduction using TRIZ	Integration of TRIZ
1	[31] Ikovenko & Bradley, 2004	Customer focus	Trimming	Integration Success
2	[32] Mann & Domb, 2007	Trade-off	Contradiction	Harmful factor
3	[45] Sawaguchi, 2002	Brainstorming	Automotive	High value idea
4	[33] Stratton et al., 2007	-	Trimming	Engineering Needs
5	[34] Domb & Kling, 2006	Challenges	-	-
6	[35] Domb, 2005	-	Potential	Manufacturing success
7	[36] Isaka, 2012	Design competitive	Trimming	Simplification
8	[37] Mann, 2004	-	Cost Matrix	-

In summary, the gap in the research is lacking in the innovative solution for DTC Strategy, this can be solved by integrating TRIZ tools in the implementation framework that is able to provide better results not just in reducing cost but also improve product innovation.

4 Implementation Framework of DTC for Product Concept Design Stage Using Triz Tools

The proposed framework as shown below is a part of product design and development process. The DTC implementation process is conducted in main four phases, prioritization of DTC system, idea generation, idea evaluation and the implementation ideas and off-line idea exploration.

Figure 3 shows the proposed implementation framework of DTC phases consist of main activities and TRIZ tools that need to be used in the processes. The most important data established initially is the target cost, and this will be the foundation of overall DTC deliverables and goals. Starting with the first phase, the product concept designs are analyzed through product analysis and components analysis.

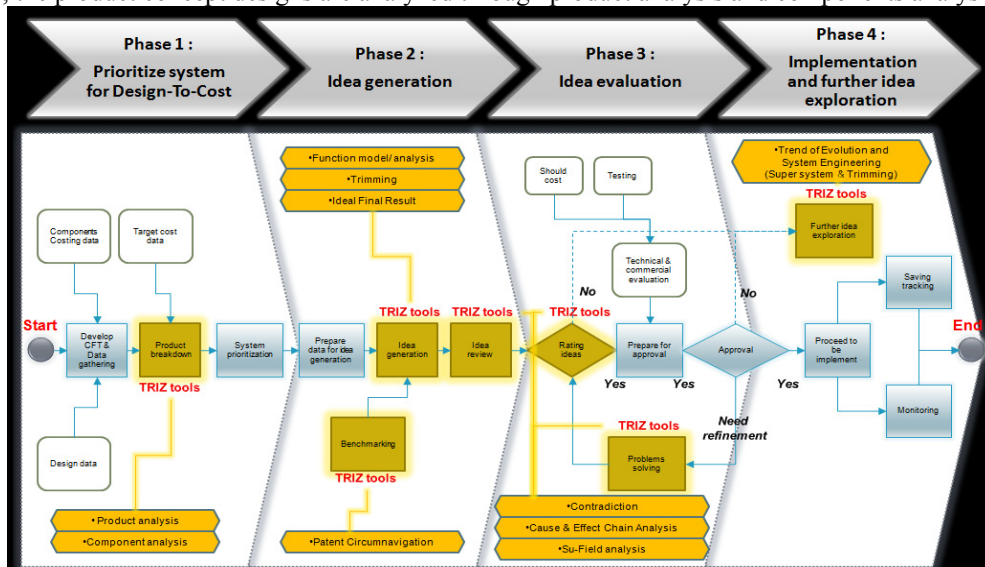

Figure 3 Conceptual DTC Strategy with TRIZ

Figure 4 shows the breakdown of the product analysis and components analysis. It provide clear identification of system that hold the biggest cost of a product. Each breakdown level are analyzed using

Pareto analysis. Those components that carry high cost are the primary focus to DTC idea generation. In the second phase, the focus on sub-system for DTC which needs to go through function analysis whereby the function model is created. As the establishment of function model, the components, object and functions provide clear pictures to carry out trimming activity.

Trimming have three types of approaches, the first approach is that function carrier can be trimmed if we remove the object of its useful function [39]. Approach stated that the function carrier can be trimmed if the object of function performs the useful function itself. This approach provides ideal solution to DTC, where the object can provide function itself using available resources of the system, surrounding environment and free or inexpensive resources. The final approach said that the function carrier can be trimmed if another component performs its useful function.

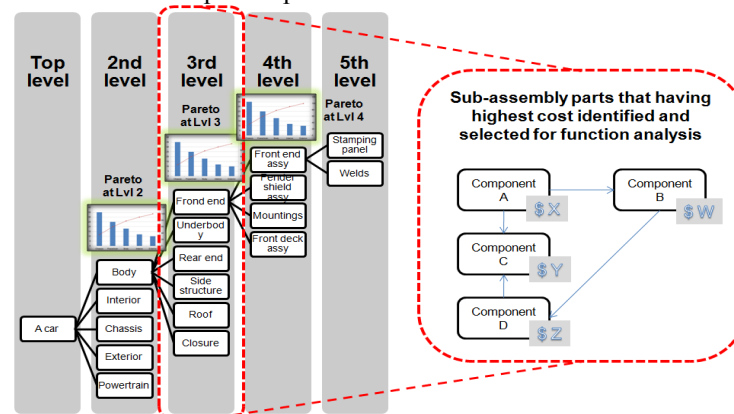

Figure 4 Product Analysis and Function Analysis

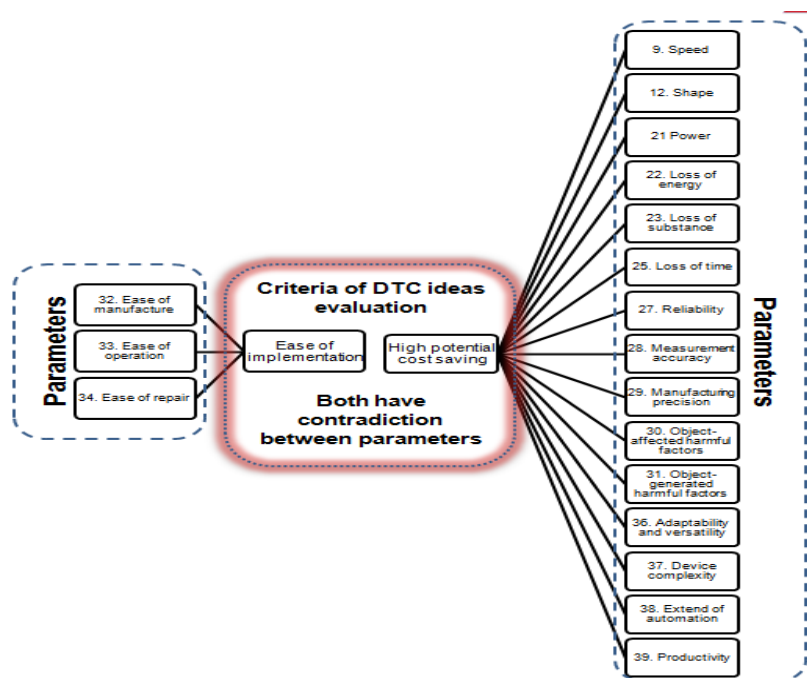

Figure 5 Criteria of DTC Idea Evaluation Parameters

In phase three, the ideas generated are rated on two criteria, ‘ease to implement’ and ‘high potential of cost saving’, as shows in Figure 5. Both play an important role to make sure the idea reduce part cost and feasible to be implemented on the product without affecting the project time line, this able to synergize the design and manufacturing [40]. Both criteria have their own parameters that are conflicting to each other, therefore the need of contradiction matrix and inventive principals’ helps to solve the problem. In this phase, the evaluations also include feedback from the testing activity. The testing activity sometime highlight problems with undiscovered root cause, therefore the use of cause-effect

chain analysis is required to investigate the root cause of problems that need to be solved. Later the ideas will go through final approval to proceed to the next phase.

In the final phase, the approved ideas will be implemented into the final design and the cost saving will be include in the financial monitoring system. Furthermore, the ideas that are not selected will be analyzed to increase the value of cost saving with TRIZ tools called Trend of Engineering System Evolution, as shows in Figure 6. The two type of trend focusing on the increase of cost saving value are Trend of Transition to the Super-system and Trend of increasing the degree of Trimming.

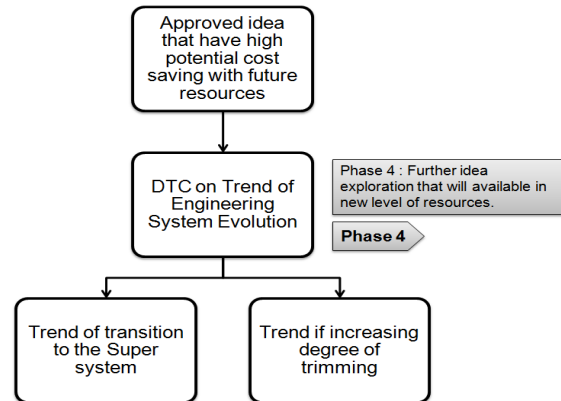

Figure 6 DTC- with Trend of Engineering System Evolution

Framework validation is important to confirm whether it is fit to a purpose. The most important thing in carry out validation is the context of validation process is carried out. The contextual factors that likely to impact the validation process are time, cost and geographical condition. The framework validations have several methods and approaches.

The approach includes reviewing research literature on related DTC and TRIZ tools application, seeking input from expert panel, undertaking empirical research, under taking survey research, conducting pilot projects and conducting case studies. In this study, the validation approach used is conducting on case studies.

The case studies approach is used in implementing DTC practices in Vehicle Cost Reduction program in an automotive company. The project has been closed contact with the DTC activity in product design and development project for new model. The intention of these case studies is to get a firmer idea of the importance of various implementation practices and the usability of framework.

5 Research Method

Literature review was performed to understand the current state with respect to Design-to-Cost and the application of TRIZ in automotive industries. Applications of strategy and tools in relevant industries we also studied. There is still research gap in applying Design-to-Cost with TRIZ methods in automotive industries. This study explores the implementation of Design-to-Cost and TRIZ in product design and concept development without using trade-off. The next step is developing the framework that represents the building block of the TRIZ-DTC components based on the researcher experience and knowledge. The framework components are organized to ensure that they are based on sound theory. Later, the TRIZ-VCR (Vehicle Cost Reduction) methodology is developed, consist of activities, principles, tools and important component that can be used to implement Design-to-Cost with TRIZ.

The Case Studies technique adopted demonstrates that the proposed framework results in cost reduction thus giving a positive impact to the organization. Several case studies were conducted in the VCR department of an automotive firm to demonstrate the usefulness and correctness of the Design-to-Cost with TRIZ framework. Lastly, the researcher developed recommendation for immediate future research that can help advance the theory and application of Design-to-Cost and TRIZ in other industries.

6 Case Study

The extensive utilization of TRIZ tools and solutions in Korean automotive manufacturing showed outstanding performance in product design and market share worldwide ^[41]. Using TRIZ tools and solutions in Design-To-Cost (DTC) expect to produce better product design by solving contradiction and generated innovative solution. This provides opportunities to achieved better product cost and thus

enhancing survival in automotive globalization market through innovation.

In the automotive industries, material usage is critical to the product design. The product design will determine the sufficient amount of material required. In this study sheet metal is selected as the focus for the DTC project. This selection is based on the material cost and the quantity of usage to manufacture a component based from metal sheet. The process of producing component from sheet metal requires a lot of energy and resources such as large stamping machine and high logistic activities from process to another with more than 200 metal parts with various types of sizes and weights and also many levels of assemblies processes.

DTC exists to improve the productivity by maximizing the utilization of sheet metal to produce stamping parts. This approach highlighted the engineering contradiction parameters between 'Productivity' and 'Area of stationary object'. The idea generation activity utilized contradiction matrix to generate a solution for this DTC activity. There are four solutions that can be extracted from the TRIZ contradiction matrix, i.e. #7- Nesting, #10-Prior Action, #15-Dynamicity/Optimization & #17- Moving to a new dimension.

Assessing on engineering perspective, the current design of blank sheet metal of "pane side outer", there is a possibility that the concept of #7-Nesting is applicable for this DTC activity. Figure 7 shows that blank sheet design that can incorporate other blanking sheet for other parts.

Based on types of material and sizes of the blank sheet metal, the engineering principles found that there are similar components that have used the same type of material or lower grade but most importantly the components must have the same material thickness, as shown in Figure 7. It is feasible to implement this in the concept design of panel side outer blanking sheet metal, and hence this provides an opportunity for engineers to expedite the concept into the product design.

One of the cost strategies of DTC is to look into the feasibility of component cost impact on product cost. The parameters of cost improvement are productivity, material usage, energy consumption, logistic cost, and manpower cost against the investment cost in providing tooling to the engineers to implement the proposed ideas. From the cost analysis done by the procurement engineers, the return of investment is positive, the estimated data highlighted that the return of investment is within two months subjected to the stability in production volume.

Figure 7 Feasibility Study of TRIZ Solution into Blank Sheet Metal of Side Panel Outer Structure.

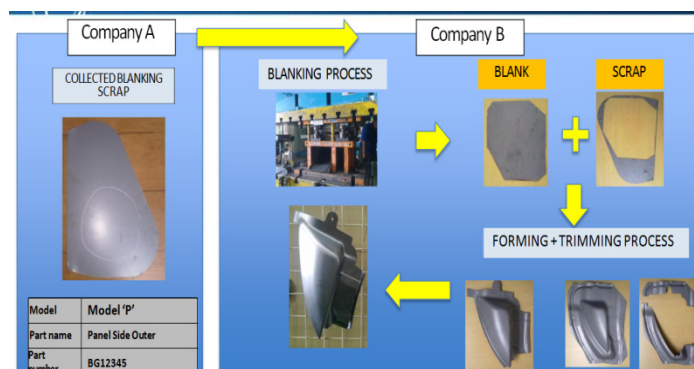

Figure 8 The Utilization of "Un-Used" Sheet Metal (Scrap) for Other Components.

Based on both analysis of engineering and costing, the idea is feasible and proceed for implementation. The un-used sheet metal from the stamping process of panel side outer, owned by company A, will be sent to company B, C and D who will invest in tooling of stamping die to process other smaller stamping components, as shown in Figure 8.

The outcomes of this DTC project saves huge raw material, energy and resource consumptions in producing the same components. There are also indirect benefits, like cost saving on logistic. The ultimate goal is also achieved through productivity improvement of more than 15%.

7 Conclusion

The aim of this study was to demonstrate a proposed framework of DTC implementation with TRIZ tools application. A case study method was used to find out whether the DTC implementation with TRIZ tools could provide successful cost reduction in product costing. With a case study presented above, the results were positive. One of the main contributions is by introducing TRIZ tools in DTC, the idea generated have managed to solve contradiction parameters that constraint the exploration of potential cost saving in a product design and development. The most critical TRIZ tools that are able to enhance the potential of cost reduction in product design are 1) function analysis and 2) trimming. The researchers believe that the cost reduction can be achieved and this case study also contributes to higher level of innovation in product development.

The TRIZ applications, using contradiction matrix, in this stamping DTC case study suit the problems. The established solutions provide guidelines for future product development and concept design, and it shows that the DTC become more effective and introduce higher product innovation. Therefore, in future research, the proposed framework could be tested and applied in other automotive products or even other types of industries in order to further refine and eliminate any weakness that the framework might still have.

Trends in Industrial R&D in India from 1996-2011: An Analysis

Nirmalya Bagchi

Professor and Area Chairperson, Technology Policy, Management and Innovation Area, Administrative Staff College of India

(Email: nirmalya@asci.org.in)

Abstract: Indian industry has traditionally been a low spender on R&D, but some industries are showing promise of higher investments in R&D. The three key industries show a trend of higher investment in R&D. This paper analyzed the number of firms conducting R&D, their expenditures on R&D, sales, and technical fees, and presented the analysis of the companies in foreign private sector, Indian private sector, central government, state government, and top 50 business houses in addition to the overall aggregate analysis. Furthermore, the paper identified industries/industry groups with high average research and development intensity over the 16 years. The results showed that the government definitely plays a role to increase the number of companies investing in R&D, either through incentives or advocacy. The models developed to find the relationship between sales and R&D investment are baseline models and need greater refinement.

Key words: R&D; Expenditures on R&D; Sales; Technical fees

1 Introduction

The contemporary wisdom and consensus amongst economists and policy makers is that investment in research and development is a way of ensuring competitive advantage of a nation. Recent studies indicate that human capital and technological progress (and innovations thereof) should be given utmost importance to ensure long term economic growth and prosperity. The experience¹ of Japan, Taiwan and other East Asian economies, particularly South Korea and Singapore show that given the right interventions and availability of a suitable eco system, developing countries can catch up on technology and innovation and in turn use the newly acquired edge in these fields to gain competitive advantage. While this is well known, and many developing countries are indeed investing heavily in technological progress in a bid to grow and develop faster, in India, this understanding is slowing gaining acceptance. The country still relies heavily on government funded research and the share of industrial R&D in total R&D expenditure of the country is quite low even in comparison to similar other economies. However, recent trends indicate that in some sectors at least like transport (auto), drugs and pharmaceuticals, non-electrical machinery and electronics, the Indian industry is beginning to invest substantially in R&D. The present paper is therefore a modest attempt at analyzing broad trends in industrial R&D industry spending in the last 16 years (1995-96 to 2010-11) so that the insights can translate into actual policy measures. Many studies have been carried out on India's industrial R&D and its impact on the economy (Desai, 1980; Rao, 2008; Mashelkar, 2008; Narasimha, 2008; Banerjee, 2012; Bhattacharya, 2007; Bagchi, 2011).

2 Methodology

We have analyzed the number of firms conducting R&D, their expenditures on R&D, Sales, Technical Fees (acquisition cost of technical know-how, technology transfer fees), Royalty, Import of Capital Goods and High Technology Exports in different sectors as well as in aggregate. In analyzing the overall aggregate scenario of R&D spending and related factors in Indian industry, we have also presented the analysis of the companies in Foreign private sector, Indian private sector, Central Government, State Government, and Top 50 Business Houses in addition to the overall aggregate analysis.

Data on Indian companies investing in R&D was first collected from 1996 to 2011. This data was the segregated into industry groups/industries (by 5 digit NIC classification). An analysis of these

¹ The experience of Japan (Johnson, 1982), Taiwan and other East Asian economies, particularly South Korea and Singapore (Kim, 1980, 1997) show that given the right interventions and availability of a suitable eco system, developing countries can catch up on technology and innovation and in turn use the newly acquired edge in these fields to gain competitive advantage. Kim (1997) after analyzing the South Korean experience posited that technological progress and the innovation thereof was a moving target and a country needs to continuously keep up efforts to remain at the cutting edge and that technological capability is not attained just by achieving an edge in R&D but in the application of R&D and its commercial exploitation.

different industries was then performed to identify industries/industry groups with high average Research and Development Intensity (RDI) over the 16 years. The industries that report high RDI indicate that they have a culture of investing in R&D. These high RDI industries are analyzed further and OLS regression conducted on their Sales (Industrial Sales) and R&D Investment (Sum of R&D Capital and R&D Current). The industries are then put in a framework and insights for policy makers can be derived from this.

2.1 Data source

The data (unless otherwise stated explicitly as a source in any table) has been collected from Prowess¹ database of Centre for Monitoring Indian Economy (CMIE) which is a standard source of information on financial performance of Indian companies (both listed and unlisted) and contains time-series data from 1989-90 till date. The Annual Reports of individual companies is the main source from which the Prowess database collects information and for listed companies the database also collects data from the stock exchanges.

3 Results and Discussion

The aggregate scenario of R&D spending in Indian industry is presented in this section. The number of firms spending any money on R&D is analyzed first, followed by the analysis of R&D manpower in Indian industry (data for which have been collected from IMD Competitiveness Online). Thereafter, the total R&D investment (which is a sum of the current R&D investment and the capital R&D investment) and the total sales of firms are analyzed. This is followed by an analysis of the technical know-how fees.

The number of companies with any R&D expenditure has not grown by a desired rate in the last 16 years. The number of firms with any R&D spending remained same from 1996 to 2000-01 and following an increase in the year 2001-02 has remained at the same value up to 2009-10 **showing a step like pattern**. The analysis of data for the last 16 years (i.e from 1995-96 to 2010-11) and also for the year 2011-12 shows that there has been a rapid increase in R&D spending by Indian Industry. Two distinct phases are evident from 1995-96 to 1999-2000 wherein the R&D expenditure by Indian Industry was choppy with a random up and down pattern, going up one year and then coming down the next (i.e. no distinct pattern was discernible). However, from 1999-2000 till date the R&D expenditure of Indian industry has grown every year and the value stood at 177216.2 in 2010-11. This value is an increase of 11.1 times over the 1995-96 value, even though the number of firms investing in R&D has reduced from 1995-96. The sales in the corresponding period has grown by 7.68 times only, which indicates that relatively firms are now spending more on R&D than earlier with respect to their sales. **The data also shows that the trend of rapid spending on R&D by domestic industry has not been affected by the recent global financial crisis.**

In terms of overall analysis we have prepared some ratio analysis² of R&D expenditure and related

¹ The database is the largest and most comprehensive database on Indian business entities. The total income of all companies in the Prowess database is about 74 per cent of India's GDP. As of 31 March 2010 there were 8,35,860 companies registered with the Registrar of Companies, (which is an administrative arm of the Ministry of Company Affairs) of which 82,822 were public limited companies and 7,53,038 were private limited companies. The profit and loss statement for the 7.5 lakh private limited companies is generally not available in the public domain and hence is not available in the Prowess database.

² The ratios are defined below:

1. Number of Firms spending on R&D / Total Firms – this ratio shows the penetration of the idea that R&D is beneficial for competitive advantage in Indian industry. Since the number of firms with R&D is such a small percentage of the total firms, we shall use only the number of firms with R&D as a proxy variable to indicate the above.
2. R&D Intensity = (R&D Expenditure/Sales) X 100 – this ratio shows the quantum of money that industry is willing to spend on own R&D to gain advantage over others, as a ratio of its sales. This indicates that the industries that are spending on R&D have realized its importance and are now allocating money in a judicious manner to increase profits through such investments in R&D. **This ratio shows the propensity of industry to create intellectual property through in-house R&D in ratio of its turnover size.**
3. Royalty Intensity = Royalty expenditure / Sales – this shows the intensity of royalty spending as a ratio of sales. This ratio indicates the money spend by industry as a ratio of sales to acquire a resource that it cannot generate in-house. The resource may be technology/intellectual property or any physical resource. **This ratio shows the propensity of industry to acquire resource (intellectual or otherwise) in ratio of its turnover size instead of creating them in-house.**

expenditures to arrive at some conclusions.

Figure 1 Sales and R&D Expenditure in Rs. Million 1995-2011

R&D Intensity shows an increasing trend and has increased from 0.24 in 1995-96 to 0.37% in 2010-11. This shows that Indian industry is spending more on R&D in proportion to their sales now than they used to in 1995-96. The pattern of expenditure on technical know-how fees is shown in fig. 2. The value of such technical fees is very small in comparison to the R&D expenditure or royalty expenditure of Indian industry. The overall trend is upward but some inflexion points are visible in 2003-04 and again in 2006-07. However, since then there is an upward trend.

Figure 2 Technical Know-How in Rs. Million 1995-2011

In terms of overall analysis we have prepared some ratio analysis of R&D expenditure and related expenditures to arrive at some conclusions. Figure 3 and 4 show the pattern of such ratios over time.

Figure 3 Pattern of RDI, Royalty Intensity and Tech Know-How Intensity from 1995-96 to 2010-11

4. Technical Know-How Intensity = Technical Know-How expenditure / Sales – this shows the quantum of money spend by industry on technology acquisition as a ratio of sales. **This ratio shows the propensity of industry to acquire technology resource in ratio of its turnover size instead of creating them in-house.**
5. External –Internal R&D Ratio = (Royalty+Technical Know-How Fees)/R&D Expenditure – this ratio indicates the **confidence of industry in its own R&D vis-à-vis in acquiring intellectual property from external sources** (which may be foreign also).
6. Pure Technical Acquisition Ratio = (Technical Know-How Fees)/R&D Expenditure +Royalty – this ratio shows the **propensity of industry to buy technology rather than make it.**
7. Total Export Translation Ratio = (High Technology Exports)/(R&D Expenditure + Royalty +Technical Know-How Fees +Import of Capital Goods) – this ratio gives the **ultimate benefit that accrues to the country in terms of foreign exchange income as a ratio of all spending in acquiring IPR.**
8. Own R&D Export Translation Ratio = High Technology Exports / R&D expenditure – **this shows the benefit of industry and country as a whole due to own R&D of industry.**

Figure 4 Pattern of Different Ratios from 1995-96 to 2010-11

An analysis of Research and Development Intensity of all the companies (segregated into industry groups) registered in India yielded the following:

Industry	RDI
Drugs	3.96
Transport	1.242
Electronics	0.957
Non Electrical Machinery	0.875
Chemical	0.397
Diversified Manufacturing	0.293
Energy	0.288
Electrical Machinery	0.274
Non Metallic Products	0.256
Services	0.205
Plastics	0.171
Food and Beverages	0.136
Misc Manufacturing	0.109
Mineral Products	0.093
Textiles	0.088
Paper	0.085
Base Metals	0.082
Leather	0.079
Construction	0.067
Wood	0.065
Agriculture	0.027

Evidently, there is a huge disparity in RDI among different industries.

The number of companies with any R&D investment has not grown by a desired rate in the last 16 years. In fact, fig. 5, shows a dip in the number of firms with any R&D spending for the year 2010-11. This dip is primarily due to a dip in the number of such companies in the drugs industry. The number of firms with any R&D spending remained same from 1996 to 2000-01 and following an increase in the year 2001-02 has remained at the same value up to 2009-10.

Table 2 - Shows the distribution of firms by turnover. Total number of firms in a turnover range and firms with any R&D spending in such turnover range are shown in four different years. The data has been captured for calendar years and not for financial years. The pattern that emerges is interesting to note.

Figure 5 No. of Firms with R&D Investment 1995-2011

Table 2 clearly shows that over the years, firms in low turnover ranges from below Rs. Million 10 to Rs. Million 50-100 are showing a drastic dip in number of firms spending on any R&D even though by and large the total number of firms in such turnover range is increasing rapidly. Over the years the trend of number of firms spending on R&D is sharply downward in this turnover range. Similarly the pattern of number of firms in the turnover range Rs. Million 100 to Rs. Million 2000 with any R&D spending shows a sharp dip from 2005 to 2010. In the Rs. Million 2000 to 4000 range the number of firms with R&D spending has remained stable and in the range Rs. Million 4000 and above, there has been a sharp increase in the number of firms spending on R&D. This shows that the firms that have the means to spend on R&D are now beginning to spend on R&D, even though in percentage terms, this is still below the 50% mark. Hence, more needs to be done on the advocacy front to impress upon the companies in various turnover ranges the need to spend on R&D. This can be handled with a policy measure that advocates higher R&D investment in industry in such turnover categories.

Table 1 Distribution of Firms with R&D and Total Firms on the Basis of Turnover in the Calendar Years (annualized) 1996, 2000, 2005, 2010

Turnover (Rs. million)	1996		2000		2005		2010	
	Total Number of Firms	Firms that spend on R&D	Total Number of Firms	Firms that spend on R&D	Total Number of Firms	Firms that spend on R&D	Total Number of Firms	Firms that spend on R&D
<10	484	6	797	1	2031	1	2129	0
10-20	258	7	335	6	586	2	474	0
20-30	207	7	260	5	407	7	318	3
30-40	197	8	187	5	315	4	240	3
40-50	173	12	175	6	264	5	179	2
50-100	583	44	683	39	895	29	698	16
100-200	729	64	811	62	1082	60	638	28
200-300	505	89	623	66	738	72	619	33
300-400	287	43	433	61	508	54	432	22
400-500	250	57	305	52	374	38	328	23
500-1000	625	176	845	151	1102	163	1067	112
1000-2000	471	197	621	157	949	182	971	144
2000-3000	180	94	276	92	389	94	462	90
3000-4000	72	42	131	59	232	72	284	66
4000-5000	54	26	74	20	156	54	202	52
5000-10000	112	71	162	80	326	133	543	173
10000-50000	89	52	143	67	277	116	566	208
50000>	17	14	29	22	70	38	144	78

The analysis of data for the last 16 years shows that there has been a rapid increase in R&D spending by Indian Industry. Two distinct phases are evident from 1995-96 to 1999-2000 wherein the R&D investment by Indian Industry was choppy with a random up and down pattern, going up one year and then coming down the next. However, from 1999-2000 till date the R&D investment of Indian

industry has grown every year and the value of such investment has increased by 11.1 times over the 1995-96 value (without discounting for inflation etc.), even though the number of firms investing in R&D has reduced from 1995-96. The sales in the corresponding period has grown by 7.68 times only, which indicates that relatively firms are now spending more on R&D than earlier with respect to their sales. The data also shows that the trend of rapid spending on R&D by domestic industry has not been affected by the recent global financial crisis.

Indian Private Sector firms shows a period of rather slow growth from 95-96 to 1997-98 followed by a jump & dip pattern which is followed by a period of steady growth culminating in a jump in R&D expenditure in 2002-03 which is followed by a period of very rapid growth till 2010-11. The R&D expenditure by Indian Private Sector companies in 2010-11 represents 58.59% of the total industrial R&D expenditure in 2010-11. The corresponding share of Indian Private Sector R&D expenditure in 1995-96 was 58.33%. Foreign Private Sector R&D has also grown in the last 16 yrs. However, there have been different phases. 1995-96 to 1998-99 can be deemed as a phase of rather choppy investments by such companies with a jump-dip-pattern. 1999-2000 to 2001-02 shows a static period in which R&D investment was flat. 2002-03 to 2005-06 there was rapid growth which is followed by a dip in 2006-07 and a jump in the next 2 years followed by a dip in 2009-10 and a jump in 2010-11. The 2010-11 value of R&D expenditure in such companies was 8.23 times the value of R&D expenditure of the same category of companies in 1995-96. It must be noted that there has been an impact of the global financial crises on investments in R&D in such companies. The 2010-11 R&D expenditure of this category of companies' represents 15.43 % of the total industrial R&D expenditure which is down from the 20.81% share which such companies had in 1995-96. It will be interesting to note that there seems to be very little or no impact of the global financial crisis and consequent economic slowdown on Central Govt R&D expenditure. The top 50 business house also shows a pattern starting with jump-dip jump from 1995-96 to 97-98 followed by a period of flat growth culminating in a period of rapid growth till 2008-9 following which there has been dip and also a revival in 2010-11 .The R&D expenditure for such companies in the year 2010-11 was 8.56 times the value of 1995-96. The 2010-11 value of R&D expenditure of such companies represents 23.96% of total Industrial R&D which is down from 31.06% for the year 95-96.

The three key industries that show promise are analysed below:

4 Automobiles and Transport

One of the industries which have regularly shown high R&D intensity is the automobiles and transport industry which includes industries in automobiles, aeronautical and other related industries. The R&D intensity of this industry in 1995-96 was at 0.58 which has steadily increased and in 2010-11 was at 1.45. The R&D investment also has grown in last 16 years from Rs 2201.5 millions to Rs 45881.1 millions which is an increase of 20.84 times and which indicates that the industry is spending heavily on R&D. The trend also shows two distinct phases in 16 years. The phase of 1995-96 to 2000-01 shows R&D investment in this industry group having a very modest growth and the second phase 2001-10 which shows a pattern of exponential growth in R&D investment. The reason for this spurt in R&D investment in the sector seems to be of tendency of several big companies to invest in R&D along with Tata Motors. Other auto companies that have started to heavily invest in R&D includes Ashok Leyland, Bosch, Maruti, and HAL. R&D investment in the transport sector represented about 25.89% of the total industrial R&D investment of the country in 2010-11 which is up from the 13.79% share of R&D investment that the sector had in 1995-96. The number of companies investing in R&D has also gone up and the royalty and technical fees paid by the firms has also gone up from 95-96.

Figure 6 Pattern of RDI from 1995-96 to 2010-11 in Auto and Transport Industry

A simple relationship between Sales and R&D investment in this industry has been developed by an OLS model. An OLS of the log of Sales (in Rs. Million) and log of R&D Investment (in Rs. Million) yields the following result:

Dependent variable: $\ln_Sales_in_Rs_Million$

	coefficient	std. error	p-value
const	7.30044	0.298355	2.94e-012 ***
Dum1	0.351977	0.130365	0.0182 **
$\ln_R_D_Expenditur\sim$	0.705734	0.0319425	1.08e-011 ***

R-squared	0.974781	Adjusted R-squared	0.970901
Durbin-Watson	2.250033		

Figure 7 - Average R&D Investment Per Firm the Auto and Transport Industry from 1995-96 to 2010-11

As is evident from figure 7, the average investment per firm has seen a very sharp increase from 2002—03 onwards and barring one bad year, the trend is secular.

4.1 Electronics

The firms in the electronics industry also show high R&D investment. In 1995-96 the R&D intensity of firms in this set of industries was 0.66, which has increased to 1.04 in 2010-11. The R&D investment is steady barring a couple of years. However the number of firms investing in R&D has gone down. In 2010-11 firms in this sector reported R&D investment of Rs 5288.70 millions which is 6.86 times the corresponding value of 1995-96 and which represents 3% of the total industrial R&D investment in the country in 2010-11. Share of Electronic firms in total industrial R&D in 1995-96 was 4.8%. The royalty paid by Electronic firms show a phase of almost very low growth from 1996-2004 after which there is a rapid increase till date. A simple OLS model developed with the time series data is given below:

Dependent variable: $\ln_Sales_in_Rs_Million$

	coefficient	std. error	p-value
const	5.81699	0.580206	9.05e-08 ***
$\ln_R_D_Expenditur\sim$	0.852347	0.0743972	1.69e-08 ***

R-squared	0.903618	Adjusted R-squared	0.896734
Durbin-Watson	1.756082		

Figure 8 Number of Firms 1995-96-2010-11

Figure 9 Average R&D Investment Per Firm 1995-96-2010-11

As evident from figure 9, the R&D spending per firm has grown exponentially since 2006-07 till date. There seems to be no impact of the financial crisis on R&D investment in this industry. Of course the top companies here are from the public sector enterprises.

4.2 Drugs

The Indian drugs and pharmaceutical industry is highly fragmented with over 20,000 registered companies. The number of active companies is about 6,000. The largest company in Indian market controls only 7 % market share and the top ten accounts for 30 % market share. The top 250 companies in the organized sector account for 75 % of the sales. The MSMEs fulfill a large part of the market. Drugs and pharmaceuticals industry has reported the highest R&D intensity in 1995-96 and also subsequently in each passing year till 2010-11. R&D intensity of firms in this industry was 1.45 in 1995-96, which has increased to 4.97 in 2010-11. In 2010-11 firms in this industry have spent Rs 43958.20 millions on R&D which is 21.54 times the corresponding value in 1995-96. In 2010-11 the share of R&D spending in this sector in total Indian industrial R&D was 24.80% which is up from 12.78% in 1995-96. However, the worrying trend for the sector is that there has been a sharp fall in the number of companies investing in R&D in the last couple of years. From the high of 127 firms it is now down to 94 firms. The R&D Investment by the firms in this sector can be categorized in to 3 phases of low growth, moderate growth, and high growth. 1956-96 to 1999-2000 represents a phase of low growth, 2000-03 is period of high growth and 2003-to ill date is a period of rapid growth. A simple OLS model for sales and R&D investment in this industry has been developed, which is as given below:

Dependent variable: l_Sales_in_Rs_Million

	coefficient	std. error	p-value
const	7.91839	0.244888	1.48e-014 ***
l_R_D_Expenditur~	0.527194	0.0263056	1.05e-011 ***
R-squared	0.966318	Adjusted R-squared	0.963912

DW is low for this model, and a better model is possible, which will be explored at a later date.

Figure 10 Number of Companies with any R&D investment in Drugs industry Between 1995-96 to 2010-11

Figure 11 Average R&D Investment for Drugs Sector 1995-2011 Ref

The figure 11 shows that in the recent past, the average investment on R&D in this industry has increased exponentially. It must be pointed out that there has been a major structural change in this industry in 2005, when India changes from a process patent regime to a product. To comply with TRIPS, India reintroduced product patent protection in drugs and pharmaceuticals from 1st Jan 2005, and hence the industry was forced to invest heavily in R&D to survive. The Indian pharmaceutical industry is building up world-scale capabilities in pharmaceutical manufacturing. Indian capabilities in manufacturing stem from a strong knowledge base in synthetic chemistry, process innovation, low-cost manufacturing and a deep understanding of the patents. In other stages of the pharmaceutical value-chain, namely discovery, development and marketing the industry is slowly building competencies. The analysis also shows that there is a lot of churn in the industry with regard to R&D investment and sales and that all the top companies are from the private sector.

5 Conclusion

Indian industry has traditionally been a low spender on R&D, but some industries are showing promise of higher investments in R&D. The three key industries show a trend of higher investment in R&D. However, Firms in low turnover ranges from below Rs. Million 10 to Rs. Million 50-100 are showing a drastic dip in number of firms spending on any R&D even though by and large the total number of firms in such turnover range is increasing rapidly. Therefore a special package of government support and advocacy for R&D investment for SMEs is required. Also, over the years the trend of number of firms spending on R&D is sharply downward in this turnover range. The pattern of number of firms in the turnover range Rs. Million 100 to Rs. Million 2000 with any R&D spending shows a sharp dip from 2005 to 2010. This calls for a special package and government intervention. In the Rs. Million 2000 to 4000 range the number of firms with R&D spending has remained stable and in the range Rs. Million 4000 and above, there has been a sharp increase in the number of firms spending on R&D. This shows that the firms that have the means to spend on R&D are now beginning to spend on

R&D, even though in percentage terms, this is still below the 50% mark. A PPP system of engaging with the private sector will work for companies in this turnover range.

The three key industries also exhibit a take-off in terms of higher average per firm R&D investment since 2004-05 onwards, which is a good sign and shows that slowly some Indian industries are taking R&D seriously as a tool for attaining competitive advantage. The incredible churn happening in each industry is also an indicator of change taking place in each industry. In many cases the predominant role of the public sector organizations is giving way to more flexible private sector companies who have taken to R&D as a means to gain greater competitiveness. However, the worrying trend is that of reducing number of companies investing in R&D in almost each of the three industries. The government definitely has a role to play here to increase the number of companies investing in R&D, either through incentives or advocacy. The models developed to find the relationship between sales and R&D investment are baseline models and need greater refinement, which will be taken up later.

Functions of Design Management on Promoting Animation Industry in China

Gong Qifang

School of Art, Huazhong Normal University, Wuhan, P. R. China, 430070

(E-mail: wuyuemaoxiu@126.com)

Abstract: The rapid development of China's design industry, as well as the diversified development trend of the enterprises' management has promoted and given rise to the formation of the design management industry. Design management, as a cross product of two important disciplines, has a very important practical significance in the operating strategy of enterprises, especially those in the art industry. The animation industry is a sunrise industry generally recognized by today's society. But, it is undeniable that the current domestic animation industry is struggling with great difficulties under the strong impact of the United States, Japan and other animation powerhouses. Relying on China's animation industry, this paper analyzes the current situation of China's animation industry and mainly discusses the positive significance of design management in promoting China's animation industry

Key words: Design Management; China's Animation Industry; Animation Industry Chain; Chinese Elements

1 Introduction

Currently, design is an essential part whether in a company or an enterprise's operating activities. However, from the perspective of macro significance, it is just a composition of the entire operating strategy. Therefore, the design should be managed as effectively and systematically as other operating activities, otherwise, the design may just be in vain. According to the users' needs, design management is to conduct research, exploitation and management activities in a systematic and organized way. It is the management on a series of design strategies and design activities conducted to mobilize the designers' creative thinking effectively and actively, to convert the market and the consumers' awareness into the new products, to influence and change people's lives in a new, more rational and more scientific way, and to maximize the enterprises' profits.

The animation industry is a sunrise industry generally recognized by today's society. But, it is undeniable that the current domestic animation industry is struggling with great difficulties under the strong impact of the United States, Japan and other animation powerhouses. This paper analyzes the reason of weakness in the domestic animation industry, and proposes to blend design management in the domestic animation industry. The integration of the rational design concept into casual design is an extremely effective way to quickly upgrade the domestic animation industry.

2 Analysis on Current Situation of Chinese Animation Industry

The animation industry which views providing spiritual products as its basic content, has distinctive differences but also the common property with the general industry. Therefore, animation products must also conform to the basic law of value in the process of production, circulation and consumption. In the course of development, it is also constrained by the supply and demand mechanism, the price mechanism and the competition mechanism. Influenced by the law of value, the animation industry must also view market as the basic orientation, and adjust various resources by the market in order to gradually form and improve the animation industrial chain. Such chain is vividly called by western countries as "smile curve", which is displayed with the original R&D in the upstream, the manufacturing in the midstream and the sales distribution in the downstream. The chain conveys the value of the specific intellectual property (or copyright) in the cultural industry. Focusing on the formation development, protection, appreciation and transformation of intellectual property rights, the chain constitutes the life cycle of the animation industry, and reflects the unique value-added charm in the cultural industry. The chain is new type of industrial chain. The industrial characteristics of the cultural industry which bears as "content is king", together with the integration of information technology and cultural industries has multiplied the value-adding capacity of the content industry and has led to new changes on its industrial chain. The chain no longer takes the form of vertical type, but the performance of a mixed code combining vertical and horizontal structure.

In China, the prospect of the animation industry is huge. Just in the case of the game industry, the data shows that China's online game users has reached 65.87 million in 2009, an increase of 33.46% compared to 2008. And it is expected that the number will hit 123 million by 2014. The number of China's online game users in the recent six years is shown in Figure 1.

Figure 1

In 2009, China's online game market size was 27.06 billion yuan, an increase of 30.2% over last year, with the online games industry remaining the largest segment of China's Internet economy. China's online game market size in the recent 10 years is shown in Figure 2.

Figure 2

Although the market is huge, most of the current market is firmly occupied by the United States, Japan and other animation powerhouses. The reason of such phenomenon is the younger- age-targeted domestic animation industry which has long been criticized by the public. For example, most domestic cartoons are being created just to meet the limited audience of juveniles, and even just primary school students. It is not at all surprising to refer to such creative ideas and creative goals as “naïve”. The younger-age-targeted cartoons, of course, are indispensable since juveniles are important target consumers, but such kind of cartoon is certainly not the only prospect of cartoon creation. If an animation film really wants to get the audience recognition, as well as achieve its commercial value, to curry favor with those “big kids” in favor of the cartoons would be a more effective and direct way due to the limited influences of juveniles. However, to make “big kids” dwelling upon with great relish is clearly much more difficult than making the younger kids laughed. And this may be the most reasonable explanation of the lowering ages of the domestic cartoons.

In Japan and the United States, which are generally recognized as the animation powerhouses, watching cartoons is not only the privilege of the children, but is also many adults’ obsession. For example, Japan's “Naruto” and “Detective Conan” are sought after by many adults and college students in China. The impacts of animation industry even surges higher waves in the United States under the propelling force of Hollywood. From the classic cartoon image of Mickey Mouse, Donald Duck, to the later Wave of Shrek, Ice Age Cyclone, American cartoons have rolled up a round of tides in terms of box office in the world.

Facing the mighty animation industry in the United States and Japan, what is the fundamental problem of the shrinking domestic animation industry? The great pressure faced by people and

companies in the industry is one of the important reasons. It is difficult for the animation companies to feed themselves by their television broadcasting incomes. Different from the television chain, television broadcasting income of cartoons is very shabby compared with their production costs. Many domestic animation production staff has said that broadcasting income of domestic animations can be described just as a drop in the bucket compared to its production costs.

As is known to all, animation derivatives are extremely important parts of the income of the animation companies and animation creators. Cartoon dolls, cartoon image of the trademark, and even the famous Disneyland in the United States, have laid a solid material foundation for the entire animation industry. However, the actual condition in China where pirates is rather rampant has casted a huge shadow to the development of China's animation industry. Pressed by the survival burden, a lot of excellent animation script writers and animation creators have turned to other higher income industries, and the rest are hard to devote them in animation creation since the great living pressure. It is generally recognized that the script is the soul of animation. Yet, the creation of a good script is bound to occupy a lot of time and effort. However, when the creation of the entire animation industry are burdened by the big bundles of surviving pressure, a lot of good ideas and trials are faced with the possibility of being rejected by the actual reviewers and even the creators themselves. Nobody dares to take a risk, and nobody dares to make new attempts, and they all stay around holding their own small positions. As a consequence, the domestic animations become more mediocre and similar, with less and less breakthroughs.

3 Functions of Design Management in Animation Industry

In view of the current development of domestic animation industry, design management can play an extremely important practical role in design strategy, design process and execution.

Figure 3

The purpose of design management is to identify and exchange ideas on using which kind of method to offer ideas to realize the value of the industry. Therefore, to grasp the opportunity of design will be the first step towards this goal. In recent years, the voice of integrating the Chinese cultural elements into cartoons has been stronger and stronger. Chinese culture is extensive and profound. It is widely rooted among the people and generally recognized by people. As a cultural industry, animation industry should actively take advantage of this favorable cultural foundation in order to get the audiences' value recognition and emotional resonance. The cartoon series "Journey to the West" (Figure 3) from the classics and the animation film "Lotus Lantern" (Figure 4) from the domestic classical legend serve as very good examples in this regard. But quite a lot of animation creators have not realized it. They lack confidence in the Chinese elements, and someone pursue the US-Japan model blindly, which has led to the nondescript in the final animations. Design does not exist independently. In the management of design strategy, the integration of Chinese elements into the design contributes to win the audiences' value recognition and emotional resonance, and to enhance the animation design's impact on the wide public. For example, the two Hollywood animated films "Mulan" and "Kung Fu Panda" (Figure 5) have achieved great success in terms of box office, and their inspirations are all from China.

Designing is a strict and circular process that is full of inquiry and creativity. The design process consists of a series of methods, and the combining of these methods can deal with the design project and solve the design problems. The design process is developed through continuous trials and tests conducted to solve the problems, and are continuously being corrected in the process of application by the designer or design team in the customer's project.

Figure 4

Figure 5

Take the music production in the animation industry for granted, it will exert an unexpected influence on the animation industry. In the movie, the artistic feature of music lies in the unity of music and picture, and its aesthetic significance lies in the unity of audio and visual. As for animations, music plays an irreplaceable important role in emotional contagion, deepening the theme, rendering the background atmosphere, expressing the characters' inner emotions and other aspects. The episode in the animated film "The Lion King" "Can You Feel the Love Tonight" is a typical example of the perfect combination of music and animation. Hayao Miyazaki's cooperation with Japanese composer Joe Hisaishi has pushed his creations to higher peaks. In domestic cartoons, "Lotus Lantern" can be certainly listed among the best bunches in terms of music. Three most popular singers Liu Huan, Jeff Chang and Coco Lee are being invited to sing at the animation. What's more, the beautiful and popular melody has made an indelible contribution to the success of the animation. Due to the characteristics of the music itself, its playback frequency is much higher than the movie. So even if the cartoon is not replayed, the highlights of the animation still emerge in the mind of audiences whenever its music sounded. And this effect is undoubtedly the desired effects of every cartoon. With the advent of the Internet era, cartoon publicity has also undergone a huge change. Microblog and other social networks has become the main carrier of the cartoon propaganda, therefore, animation collections with theme songs have become the main propaganda pattern of animations. Wonderful music can help cartoons to get the public's attention quickly, and is critical to the success of the animation.

In the process of design, good music is often required and stressed by designers, however, is lack of sound management in the designing and implementation process. Management on design process and implementation can effectively promote the reflection of the essential design elements in the final design work, thus ensuring the quality of the design work.

3 Conclusion

The substance of the design management means managing design projects, which is far more than the simple project management. As a management method, design management has extremely important significance in the art industry. In the aspect of animation industry, design management can build a rigorous design process, to integrate the members of different professions and areas with different personalities into a high-performance design team. It can further promote technological breakthroughs

and cooperation in different fields, and to ensure that the important design elements highly recognized by designers can be reflected in the final design work. Therefore, the rational use of design management has a very important practical significance to promote China's animation industry.

Research Overview of the Evaluation Index System on the Development Level of Public Libraries

Chen Yaqian

Archive, Wuhan University of Technology, Wuhan, P.R.China, 430070

(E-mail: 493844763@qq.com)

Abstract: Through the analysis on the researches of the evaluation on public libraries in the recent years, the papers finds out that the evaluation on development level of the public libraries at home and abroad include performance evaluation, academic evaluation as well as policy evaluation of public libraries. Although there are no systematic and detailed index evaluation systems to assess the development level of public libraries, yet relatively mature assessment methods have been figured out, including return on investment, contingent valuation method and so on. To make the national public libraries develop in a rapid and robust manner, the libraries in our nation should actively establish comprehensive evaluation index systems with good economic benefits to assess the development level of public libraries.

Key words: Evaluation system of development level; Performance evaluation; Policy evaluation; Academic evaluation

1 Introduction

Since 1960s, with the continuous upgrade and deepening of management philosophies and styles on public libraries, the circle of public libraries at home and abroad brings in the evaluation of the management on the internal working states of public libraries and ushers in the researches and practices concerning the evaluation on the performance of libraries. Meanwhile, with the continuous development of information technology and network technology, the status of public libraries as the center of community information and documents will definitely be shaken. In order to attract the attention of the general public, organizations and government institutions again, the public libraries begin to focus on their operational effects and benefits, which makes a large number of relevant researches in the circle of library science spring up.

2 Literature Review

At present, a large number of research results have been achieved by the empirical studies carried out and different evaluation methods and diversified evaluation index applied by domestic and foreign library science circle concerned with public libraries. According to the CNKI (China National Knowledge Infrastructure), the main researches in this area are provided in the Table 1.

Table 1 The Main Research of Evaluation Index System on the Development Level of Public Libraries

Research Content	results
The evaluation index systems of public libraries	53
The evaluation on the performance of public libraries	27
the academic evaluation of public libraries	3
The policy evaluation of public libraries	0

Firstly, the evaluation index systems of public libraries is the most important part in this area. With the rapid development of information technology and network technology, the importance of the digital resources of public libraries constantly improves. The researches on the evaluation index systems of the public libraries at home and abroad can be mainly divided into two categories, that is the researches on the evaluation index systems based on digital resources as well as the researches on the evaluation index systems based on services and users^[1]. According to the statistics based on current researches, the evaluation index systems of digital resources include ISO/TR 20983, ISO2789 standard appendix A, ARLE-metrics and EQUINOX^[2-5]. In 1999, Fred Health, Colleen Cook et al in Texas A&M University began to apply the tool of SERVQUAL used in company evaluation into the evaluation of libraries. Under the assistance of American Academic Research Library(ARL), the research results were named as “LibQUAL+ ®”, which is regarded as one of the projects concerning StatsQual, the evaluation collection of tools about ARL. After overall test, LibQUAL+®, as the evaluation tool

targeted at service quality, is applied in non-profit libraries to improve its service standard^[6-7].

The researches of evaluation on the public libraries in our nation was initiated in 1990s. The relatively authoritative evaluation index system is the national provincial level library evaluation standard, which is formulated by China Society for Library Science and other relevant organizations launched and organized by the Ministry of Culture in our country and is adopted to evaluate index systems of the provincial level public libraries. Since 1994 to now, it upgraded four times and the newest version is issued in 2009^[8].

Secondly, the results of the evaluation on the performance of public libraries shows that this research content is less published. From the 1960s to now at abroad, the evaluation on the performance of public libraries turned from the quantitative evaluation on the input data to the evaluation on the service contents and service effectiveness of libraries and the focus of it gradually lies in the evaluation of service results of libraries^[9]. In the 21st century, the empirical studies on evaluation on the economic values of foreign public libraries increase, for example, Thomas Lynch and Julie Harrington^[10] in Florida State University and Pearl M. Kamer^[11] in Long Island Association applied the Regional Economic Models (REMI), Input/Output Models and cost benefit analysis to evaluate the performance of public libraries. The research employed two subsystems, the direct value obtained by the users and the added value obtained by the users. The emphases of the library performance evaluations at home and abroad are quite different. The foreign researches are inclined to focus on the economic benefits created by the libraries for the communities, such as the added income and the work opportunities and so on and so forth. These libraries include Florida Library in the United States, the Public Library in Suffolk County and British Library etc. In our country, from the end of the 1980s, the scholars began to explore the library performance evaluation^[12]. The evaluation system of this type in our country mainly focuses on the evaluation on the library operation and internal performance from the angles of efficiency and benefits; however, it does not highlight the total value of the libraries and neglects the establishment of the evaluation index systems concerning the added values of the libraries. Similarly, the researches regarding the construction of index systems on the library performance, services and direct economic values are relatively in a large number, such as the Construction of the Evaluation Index Systems on the Benefits of the Libraries^[13] written by Luo Jianli, the Construction of Evaluation Index Systems on the Performance of Libraries with the Orientation of the Users' Demands^[14] written by Bai Xili and so on.

Thirdly, the academic evaluation and policy evaluation concerned about public libraries are rarely discussed. The researches on the academic value evaluation of public libraries conducted by scholars in the circle of library science at home and abroad are few and far between. In CNKI, through the searches according to the searching conditions of "title", "subject", "key words" and "abstract" by the key words of "public libraries" and "academic", 25 relevant articles are finally found out after deleting the articles appearing repeatedly. However, there are no researches regarding academic evaluation standard systems of public libraries and there are no researches concerning value evaluation of academic information obtained by other relevant social institutions (such as private enterprises, folk groups) through public libraries. Among these articles, Hu Jun, Liu Ying^[15-16] et al mainly evaluate the academic values of the public libraries in the aspects of the number of issued documents and citation frequency, download, H-value evaluation and so on in the libraries.

The researches on the policy evaluation towards relevant local libraries in the circle of the libraries in our country are weak. In CNKI, through the searches according to the key words of "public libraries", "policy evaluation" and "regulation evaluation" by the searching conditions of "title", "subject" and "key words" respectively, there are only two articles left after deleting the similar ones. Starting from the evaluation standard of public policies, Xiang Xiaodan briefly divides the policy evaluation standards into the standard of scientific outlook on development, effect standard and professional standard^[17]. He Yun further researches the evaluation index of public libraries, which are the evaluations mainly in the aspects of the construction of infrastructures of public libraries, the outlay problem as well as the services for the readers^[18]. According to the current researches on policy evaluation, at the present stage of our country, the policy evaluations of public libraries are few and far between and the evaluation index systems are relatively macroscopic without further deepening and segmentation. However, the circle of library science in our country conducts abundant researches on policies of the relevant local libraries and focuses on the relevant policies and regulations of the government. The relevant index systems they put forward lack detailed segmentation of policy research systems of public libraries. Most researches mainly start from the construction of framework. Although they put forward the general direction and the contents to evaluate the policies of public libraries, they are short of the systematic and comprehensive evaluation of the influence of relevant polices on the development of public libraries,

thus being unable to effectively conduct evaluation scientifically and systematically towards the policies issued by the government and provide the valid data to support the policies issued by the government. In the further researches, the evaluation systems should be detailed segmented to feasibly serve the government in the formulation of the policies regarding public libraries.

3 Evaluation Methods

With the increase of the researches concerned with the evaluation on the economic values of public libraries at home and abroad, the evaluation methods tend to be more and more scientific and method systems become more and more perfect. According to the current research statistics, there are several main methods applied by the circle of library science at home and abroad:

Return on Investment (ROI). ROI refers to the values should be obtained through investment. If we employ this approach into the operation of libraries, it means that the every dollar invested into the services of the library can generate the return of investment of several dollars for the society^[19].

Contingent Valuation Method(CVM). The method is put forward by Ciriacy Wantrup S. V. in 1947. In the 1990s, the American scholars Arrow K. and Solow R. propose to apply CVM to evaluate the standard frameworks^[20] on the basis of the researches conducted by the previous scholars.

Balanced Scorecard Method is to divide the library performance evaluation into five parts--the organizational vision, input and output, the services for the readers, internal business, study and growth. Through the comparisons between the spot data and future expected data of these indexes, it clarifies the strategic orientation of the development of libraries^[21].

Consumer Surplus. This method refers to that the differentials between the price the customers have paid and their expected price of the product or service in purchasing a product or service.

Time Costs Method. This method is based on this hypothesis: the advantages obtained by people when applying the libraries should at least be equal to the time cost they paid in order to gain these services.

At present, the researches about the evaluations of libraries in our country are mainly concerned with the aspects of the internal services, operation, management and so on about the libraries, which lack researches on the construction of evaluation index systems integrating the social added values.

4 Conclusion

Above all, the circle of library science in our country mainly focuses on the evaluations of the internal services of libraries and performance of libraries. In addition, the evaluation systems concerned with relevant public libraries have been established. However, they are limited to the establishment of evaluation index systems on the performance of libraries. The researches on the construction of evaluation index systems concerned with the added values and the generated economic values of the libraries are few. The current research results do not contain the evaluation index systems about the development potential of public libraries under development and the total social values they produce. The further and detailed researches on the evaluation systems on academic values and policies of public libraries are not many. There are short of value evaluation researches about the academic information obtained by other relevant social institutions(such as private companies, folk groups and so on). The researches on policy evaluation index systems have not met the standards to support the policies issued by governments and the management and operation of libraries. There are in need of comprehensive evaluation targeted at the development level of public libraries, by which the corresponding researches of evaluation systems can be constituted. Taking the national conditions and financial problems of public libraries into consideration and under the boom of the construction of the cultural undertaking in the period of the implementation of the 12th five-year plan, the libraries in our country should positively set up the evaluation index systems with comprehensiveness and economic benefits on the development level of the public libraries, which may provide the standardized, economized and systematized evaluation systems for the development and construction of public libraries and boost the further development and prosperity of the undertaking of public libraries in our country.

2 Professor and Head of Marketing Department of Faculty of Business & Accountancy Building, University of Malaya (UM), Kuala Lumpur
(E-mail: bindahe@yahoo.com.uk)

Abstract: The purpose of this paper is to propose a conceptual model which would provide a better understanding on how social influences through the effect of peer communication could interplay with materialism to capture the effect of young adults' adoption of technological innovation in their life. This paper provides a brief review on the theories associated with the adoption of technological innovation as well as some important empirical findings to support the model of this study. Based on a review of established studies, this paper re-examined the relationship between peer communication and the adoption of technological innovations and propose that young adults' interaction with their peers have significant positive effect on their adoption of technological innovation. However, this paper argues that the effect is not direct. This paper proposes that the relationship between peer communication and the adoption of technological innovation could be indirect, through the relative mediating effect of materialism. Next, the relationship between materialism and the adoption of technological innovation is examined, taking into account the antecedents of materialism. Finally, the paper concludes with a discussion, limitations and the possible areas of research which researchers could explore in the future.

Key Words: Young adult consumers; Peer communication; Materialism; Adoption of technological innovation.

1 Introduction

Imagine living in a world without innovation. As human beings we consider it normal that the world around us is changing and that something old is replaced by something new. Innovation is defined in different ways (Rogers, 2003) emphasis the outcome, Schilling (2008) the creativity, Trott (2008) see it as the process from idea towards new product or process.

Rogers (2003) stated the characteristics of the innovation as important. Characteristics of innovations are the relative advantage the innovation, visibility of innovation, and compatibility of the innovation. There are also individual factors involved in innovation. Rogers (2003) found that individuals show a degree of 'innovativeness'. The intention to adopt innovations is also of importance. If the intention is low, it is unlikely that the innovation is adopted. Kabbar and Crump (2006) found other individual factors such as sex, age and education to have an impact on innovation. For instance, women, elderly and low-educated are less likely to adopt innovations.

Talukder (2008) found that social factors like the influence of peers and social network were important in adoption of innovations. Specifically, peers influence the adoption by encouraging to use or not to use the innovation. Given that peer exert a certain degree of influence on the adoption of innovation, this paper is an attempt to provide an insight into how peer influences, in particular peer communication, exert its influence on the adoption of technological innovations among young adult consumers. Behavioural sciences and individual psychology, suggest that social influences and personal traits such as individual innovativeness are potentially important determinants of adoption, and may be an important element in potential adopters' decisions (Lu et al. 2005).

While there exist a large body of studies examining the effects of social influences on the adoption of innovation. To date however, models developed to study the adoption of technological innovation have not given due considerations to variables, such as materialism, which could have an interplaying role in explaining consumers' adoption of technological innovation. In this article, materialism is highlighted a possible mediator in explaining the effect of peer communication on young adults' adoption of technological innovations.

As such, the main purpose of this paper is to propose a conceptual model to establish the relationship between peer influences towards the adoption of technological innovations in general. Specifically, the objectives of this study are:

(1) To examine the influence of peer communication on the adoption of technological innovations among young adult consumers

(2) To examine the influence of peer communication on materialism among young adult consumers.

(3) To examine the influence of materialism on the adoption of technological innovations among young adult consumers

(4) To establish materialism as a mediator in the relationship between peer influence and on the adoption of technological innovations among young adult consumers

Past studies have empirically tested the relationship between peer influences, particularly peer interaction on the adoption of technological innovations among consumers. Studies have also established the link between peer communication and materialism. This study is an attempt to provide a conceptual model which incorporates materialism as a mediator in the relationship between peer communication and the adoption of technological innovations, thus, fulfilling a research gap in the literature. By so doing, this paper will hopefully provide some further insight into understanding how consumers adopt technological innovations into their life.

2 Review of Literature

The following section lay down the theoretical background of the study, before proceeding to the development of the conceptual model to explain the influence of peer communication on young adults' adoption of technological innovations. Based on both theoretical and empirical evidence, several propositions are made. Figure 1.1 presents the conceptual model of this paper.

2.1 Adult socialization

According to Goodwin and Sewall (1992), socialization can be studied from several perspectives. Psychologists tend to focus on individual learning processes. Anthropologists focus on becoming part of a culture. Sociologists, on the other hand, often view socialization in terms of role acquisition.

Figure 1 Proposed Conceptual Model

When compared to research on childhood and adolescent, adult socialization has been relatively neglected. Brim (1966, 1968) identifies a number of differences between childhood adult socialization. First, Brim suggested that socialization consists of learning the role demands of society. For children, the reference group which prescribes role demands is composed of parents and peers; in contrast, adults refer to earlier friends, great figures in history, spirits.

Second, adult socialization necessarily builds on the foundations of childhood socialization. Berger and Luckmann (1966) suggest that this “secondary” socialization occurs on a shallower level. People may experience an inability to take on values and behavior which contradict earlier learning (Brim, 1966), also described as “resocialization” (Campbell, 1975).

Finally, as people move through the life cycle, “the emphasis in socialization moves from motivation to ability and knowledge, and from a concern with values to a concern with behaviour” (Brim 1966, p. 26). Childhood socialization develops primary motives, while adult socialization focuses on secondary motivations. The motivation adults bring to a new environment will influence their socialization because, unlike children, adults select their socialization experiences (Brim 1968).

2.2 Adoption of technological innovations

This study is interested in the adoption of new technologies in general and does not focus on a particular category of adopters as proposed by Rogers (1983). Adoption refers only to the initial acceptance of an object. Rogers (1983) classified adopters of innovations into five categories: innovators, early adopters, early majority, late majority, and laggards. For initial and early adoption, decision-making is exposed to variables other than those incurred by the technology itself and is more

possibly influenced by those variables (e.g. Ajzen and Fishbein, 1980; Karahanna and Straub, 1999; Rogers, 1983).

When examining the history of technology adoption research, many scholars in the social sciences have concentrated on the relationship between personal attitudes towards a new technology and the actual behaviour that derives from these attitudes. They often employed the Technology Acceptance Model or 'TAM' (Davis, 1989), which builds upon the theories of reasoned action and planned behaviour, both of which argue that an individual's attitude towards a certain behaviour and perceptions about the individual's own performance will determine the actual execution of this behaviour (e.g., Fishbein, and Ajzen, 1975; Ajzen, 1985).

TAM posits that the intention to use a new technology and its actual acceptance depend upon the manner in which people perceive a technology to be useful and easy to adopt. The model suggests that intention to use a technology is equivalent to actual usage acceptance.

2.3 The influence of peer communication on adoption of technological innovations

Another important insight is that although impersonal marketing methods like advertising and media stories may spread information about new innovations, but it's conversations that spread adoption (Robinson, 2009). According to Robinson (2009) because the adoption of new products or behaviours involves the management of risk and uncertainty. It's usually only people that an individual personally know and trust – and who have successfully adopted the innovation themselves – who can provide credible reassurances that change and adoption won't result in negative consequences such as embarrassment, humiliation, financial loss or wasted time.

They are on the lookout for advantages and tend to see the risks as low because they are financially more secure, more personally confident, and better informed about the particular product or behaviour. Often they will grasp at innovations on the basis of no more than a well worded news article. The rest of the population, however, see higher risks in change, and therefore require assurance from trusted peers that an innovation is do-able and provides genuine benefits.

As an innovation spreads from early adopters to majority audiences, face-to-face communication becomes essential in the decision to adopt. As suggested by Rogers (2003) this principle is embodied in the Bass Forecasting Model, which illustrates how face-to-face communication becomes influential over time. Many diffusion-style campaigns now consciously attempt to utilise Opinion Leader techniques or various "viral marketing" methods. These methods – which are becoming increasingly popular – aim to recruit well-connected individuals to spread new ideas through their own social networks.

Both Rogers (1995) and Valente (1995) noted the importance and influence of interpersonal networks on the adoption of innovations by individuals. Rogers has discussed the concepts of homophily and heterophily in communication networks. "Homophily is the degree to which a pair of individuals who communicate are similar" (Rogers, 1995, p. 286). The common beliefs and understandings between the individuals increase the likelihood that communication will be effective. It is noted that homophilous communication can limit the spread of an innovation to the individuals within the same network.

This finding is validated in a study by Durrington et al. (2000) where a group of university faculty's adoption of technology use was hindered due to lack of communication between friendship networks. In contrast, heterophilous communication is not as easy as homophilous communication due to differing beliefs, but is crucial in diffusion in connecting dissimilar individuals. Valente (1995) approaches the studying of diffusion of innovations from the standpoint of examining the social network of individuals. He posits "diffusion is a communication process in which adopters persuade those who have not yet adopted to adopt" (p. 2)

According to Valente (1995), contagion is a term referring to an interpersonal process of "how individuals monitor others and imitate their behaviour to adopt or not adopt innovations" (p. 12). The processes of cohesion, popularity, or system-wide occurrence define the individuals in the network who influence others. Valente's relational diffusion networks reflect the idea that "direct contacts between individuals influence the spread of an innovation" (1995, p. 31). Rogers suggests "we must understand the nature of networks if we are to understand fully the diffusion of innovations" (1995, p. 304).

Based on a review of the literature above, it is proposed that peer communication will have an effect on young adult adoption of technological innovations:

P1: Young adult consumers who communicate more frequently with their peers tend to adopt technological innovation earlier as compared to those who communicate less frequently with their peers.

2.4 The influence of peer communication on materialism

Pioneering studies in the domain of consumer socialization suggested that, as a socializing agent, peers are more important than family for adolescents while young teenagers are more sensitive to the social meaning of consumption because of their strong self-expressive orientation (Moschis and Churchill, 1978; Moschis and Moore, 1979a; Moschis and Mitchell, 1986). Moschis et al. (2009) have developed the 'life course' approach is a recent interdisciplinary movement in consumer behaviour research that operated as an important overarching framework to study the development of materialism in Malaysia. In their study, a survey of young Malaysian adults (18 to 22 years) was undertaken to test hypotheses derived from the life course literature. Consistent with previous research findings, television viewing and peer communication during adolescent years had a significant association with materialistic values held by young Malaysian adults.

Santos and Fernandes (2011) explained that experiences in adolescence are of major importance in building patterns of behaviour, including in the adult phase. Drawing from socialization theory and studies on materialism, their study aimed to investigate the formation of materialistic behaviour among adolescents, researching the antecedent variables of this behaviour. A theoretical framework, based on two important research streams - socialization theory and socio-familiar structure - was developed and tested through two surveys, the first one with 460 adolescents and the second with 190 just-adults. Specifically the result of the study indicated that adolescents' level of contact with their peers indicated higher degree of materialism.

Another recent study by Bindah and Othman (2012) among young adult consumers in Malaysia has found significant differences between peer communication and materialism. The more frequently young adults interacted with their peers, the more likely they tended to be more materialistic.

Based on the empirical evidence derived from a review of literature on the effect of peer communication and materialism, the following proposition is made:

P2: Young adults who communicate more frequently with their peers tend to be more materialistic in comparison to those who communicate less frequently with their peers.

2.5 The relationship between materialism and adoption of technological innovations

In an enlightening study by Donthu, and Cherian (1995) on ethnic population, materialism was used to explain the hypothesized differences in the coefficient of innovation and the coefficient of imitation in the sub-groups. In their study, materialism was operationalized as valuing of relationships with money and material over relationships with people (Belk, 1985). The basic proposition was that those with higher materialism scores would be more likely to adopt innovations, implying higher coefficients of innovation. Conversely, those who had lower materialism scores should have lower coefficients of innovation. In their study, materialism was measured by a six-item five-point Likert scale, and had a Cronbach alpha of 0.88. Their findings confirmed that those with low materialism scores have lower coefficients of innovation.

Based on the empirical evidence derived from the review of literature on the effect of materialism on adoption of innovation, the following proposition is made:

P3: Young Adults who are more materialistic will tend to be early adopter of technological innovation, in comparison to those who are less materialistic.

3 Justification of Materialism As a Mediating Variable

Past studies have examined materialism as a dependent variable. Factors which were found to be correlated with materialism can be categorized as personal, social and behavioural and demographics. Past studies have treated these factors as antecedents of materialism. For instance, social utility, vicarious consumption reasons for viewing commercials, and amount of money available were predictive of materialism. Social utility reasons for watching TV shows, social utility reasons for watching TV ads, peer communication and gender were all predictive of materialism.

Other studies have examined materialism as an independent variable. Past studies have been conducted to identify factors which were correlated with materialism. These factors were treated as consequences and include happiness, life satisfaction, conformity behaviour, antisocial behaviour, conspicuous consumption, compulsive consumption and impulsive consumption (for e.g., Dawson, 2011; Podoshen et al. 2011; Chavosh et al. 2011).

Recently, Bindah and Othman (2012) have examined the influence of socialization agents on the compulsive buying among young adult consumers, and the study has proposed materialism as a mediating variable in the relationship between family communication, television viewing and peer communication on the development of compulsive buying behaviour of young adult consumers. Another

study by Bindah and Othman (2012) which examined the effect of family communication on life satisfaction among young adult consumers have proposed materialism as a mediating variable, in the relationship between family communication and life satisfaction.

4 Conclusion

The purpose of this paper was to propose a conceptual model to provide a better understanding on how peer communication could exert its influence on young adults' adoption of technological innovations. Based on theoretical and empirical evidence, this paper first illustrated the direct effect of peer communication on young adults' adoption of technological innovation. Next, the indirect effect of peer communication on young adult's adoption of technological innovation was established by taking into account the effect of materialism as a mediator in the process. It has been proposed that young adult consumers who communicate more frequently with their peers would tend to adopt technological innovation earlier as compared to those who communicate less frequently with their peers. Secondly, young adult consumers who communicate more frequently with their peers would tend to be more materialistic in comparison to those who communicate less frequently with their peers. As a result of their high materialistic inclination, it has been proposed that young adults who are more materialistic will tend to be early adopter of technological innovation, in comparison to those who are less materialistic.

However, although this paper has attempted to provide insight on young adults' adoption of technological innovation, it has its own limitations. However, careful consideration must be made in empirical testing of this model. As a general rule, assumptions in any case 'must' and 'should' always be avoided. Assuming that peer communication will exert the same amount of influence in all the five different categories of adopters of innovation would prove wrong. It could be that peer communication exert more influence among early adopters but exert less influence among late majority of adopters of innovation, or vice-versa. For instance, it could be that early adopters are on the lookout for advantages and tend to see the risks as low because they are financially more secure, more personally confident, and better informed about the particular product or behaviour. Thus, peer communication may not have much effect on early adopters of technological innovativeness but more into other categories of adopters.

Lastly, this paper was an attempt to formulate a conceptual model with attention to a particular stage of life cycle, i.e., young adult consumers. Studies showed that those with lower materialism were significantly older (e.g., Donthu, and Cherian, 1995). Being older, also leads to lower coefficients of innovation and higher coefficients of imitation for the following two reasons: (i) older people are more resistant to change; (ii) having larger families and lower income leads to less discretionary income, which in turn leads to a lower likelihood of adopting innovations perceived as non-essentials. Future research could explore how these differences in life cycle stage would affect the adoption of technological innovation.

The Research on Relationship Between Competency and Job Performance of Marketers*

Du Dayou, Ma Lu

School of Management, Guangxi University of Science and Technology, Liuzhou, P.R.China, 545006

(E-mail: ddy1987@126.com, glx_malu@gxut.edu.cn)

Abstract: Through the analysis of the 201 valid questionnaires, we prove that the marketers' competency can be divided into six dimensions, management and decision ability, market development ability, interpersonal ability, communication skill, professional knowledge and personality traits. This six competency dimensions have significantly positive correlation with job performance, and market development ability has strong effect on task performance, interpersonal skill has strong effect on relationship performance. We also find that there is positive correlation between task performance and relationship performance.

Key words: Marketers' competency; Job performance; Task performance; Relationship performance

1 Introduction

The research of the marketers' competency can help enterprises to manage the marketers more effectively, and the exploration of the relationship between marketers' competency and job performance can provide guidance for the construction of marketers' team, it can point out the behaviors that can promote job performance, and the characteristics that have less impact on job performance. It can provide a reference for the enhancement of the marketers' ability, marketers can recognize their own shortcomings, as well as the gap.

McClelland(1973) published a paper 《Testing for Competency Rather Than Intelligence》, proposed the concept of competency. Subsequent scholars supplied the concept of competency, and Spencer(1993) defined competency as individual characteristics that can distinguish the performance of employees, it contained knowledge, cognition, attitudes, values, motivation, self image, traits, behavior that can be measured. Wang and Wang(2006) divided the quality of the marketers into five, ability quality, personality characteristics, knowledge quality, personality characteristics and physical quality. Han and Zhao(2006) summarized the marketers' competency according to the knowledge, skills, social roles, self concept, characteristics, motivations, ability and so on. Song(2007) researched the factors that can influence the sales staff performance. It found that excellent sales staffs perform significantly better on the quality of influence, initiative, service consciousness, communication skill, oral communication ability, interpersonal understanding ability, information collecting ability and responsibility.

Marketers need to be able to plan and organize their work, at the same time they also need to judge according to the market situation, to determine how to do next work, and to arrange future marketing activities and so on, so marketers need to have management and decision ability. Enterprises need to constantly expand the scope of the market of their products or services, from city to country, from one city to another city, from youth to old age group, so marketers need to probe into the market, continuously improve the market share of products or services. All the activities are associated with a variety of community, may be associated with the government for the entry of market, may be associated with media for the display of products or services, also may be direct contact with consumers for the promotion of products or services, which requires marketers have interpersonal ability and communication ability. Marketers should have certain professional knowledge, and the knowledge of the products or the services in order to show better on the characteristics of the products or the services. Marketers should have patience, honesty, integrity and the sense of responsibility which can help marketers do better job. Based on the analysis above, we put forward the following hypothesis:

H1: Marketers' competency can be divided six dimensions, management and decision ability, market development ability, interpersonal ability, communication skill, professional knowledge and personality traits.

Taylor(1911) found that the difference of the employees' work performance can be due to the difference of the personal ability. Barren and Depinet(1989) pointed out the level of the intelligence test

* This paper is supported by Guangxi Natural Science Fund Project: Performance evaluation and control system research of strategic management (GUIKEZI0481045)

scores has less influence on job performance. Borman and Motowidlo(1993) put forward performance of employee was made up of task performance and relationship performance which got recognition of scholars. Task performance is prescribed by the organization activities. Relationship performance is not associated with specific goal or task, however it can improve the effective of the group. It includes cooperation and mutual assistance, the roles outside activities, the completion of task with enthusiasm and determination, and the maintenance of organizational goals. Conway(1996) researched the validity of task performance with relationship performance, supported the point that job performance can be divided into task performance and relationship performance. Wang and Li(2003), Luo and Zhu(2006) also supported the point that job performance was made up of two factors. Based on the analysis above, we put forward the following hypothesis:

H2: Marketers' job performance can be divided into two factors, task performance and relationship performance.

Zhang(2005), Chen(2006) researched the relationship between marketers' competency and job performance, found that each dimension had significantly positive correlation with job performance. Feng and Ji(2007) researched the relationship of manufacture management competency with job performance, found that each competency had promoting effect on the performance. Lin and Wang (2008) found competency could promote performance, and it was different of the influence degree of each characteristic. Huang and Zhao(2011), Ma and Qiang(2012), Chen(2012) came to a conclusion that each competency has positive correlation with job performance. Based on the analysis above, we put forward the following hypothesis:

H3: There is positive correlation between marketers' competency and job performance.

Based on the division of job performance, this hypothesis has two hypothesis:

H3a: There is positive correlation between marketers' competency and task performance.

H3b: There is positive correlation between marketers' competency and relationship performance.

2 Research Method

This research adopts questionnaire research method, the questionnaire includes two parts, the marketers' competency questionnaire and marketers' job performance questionnaire. Through the literature research, we get marketers' competency characteristics, then consult relevant human resources experts to determine the characteristics of marketers' competency. For the part of marketers' job performance questionnaire, we refer to the questionnaire of Liu(2009) to design task performance and relationship performance. We issued 400 questionnaires in Henan, Guangxi and other eight provinces of China, and got 201 valid questionnaires at last.

3 The Test and Analysis of Research Hypothesis

3.1 Marketers' competency dimension analysis

Through relevant inspection and mutual inspection of the collected data, we get KMO index 0.818, Bartlett 810.005, df 231, Sig 0.000. Marketers' competency can be divided into six dimensions by exploratory factor analysis. Management and decision ability, the rotation characteristic value is 2.952, the variance contribution rate is 13.420%. Market development ability, the rotation characteristic value is 2.673, the variance contribution rate is 12.151%. Interpersonal ability, the rotation characteristic value is 2.177, the variance contribution rate is 9.897%. Communication skill, the rotation characteristic value is 2.231, the variance contribution rate is 10.141%. Professional knowledge, the rotation characteristic value is 1.599, the variance contribution rate is 7.270%. Personality traits, the rotation characteristic value is 2.429, the variance contribution rate is 11.041%.

3.2 Marketers' job performance dimension analysis

Through the analysis of the marketers' job performance questionnaire collected data, KMO index is 0.717, Bartlett is 303.859, df is 55, Sig is less than 0.001, it is good for factor analysis. We get standardized data first, and then carry on the exploratory factor analysis. Factor 1 gets to 38.504% for the cumulative variance contribution, and factor 2 can reach 23.685%. The variance contribution rate is high, so it has good structure validity.

3.3 Correlation analysis

The correlation coefficient is as shown in table 1(v1 is management and decision ability, v2 is market development ability, v3 is interpersonal ability, v4 is communication skill, v5 is professional knowledge, v6 is personality traits, v7 is task performance, v8 is relationship performance), the Sig level is less than 0.01. It is shown that each marketers' competency dimension is positively correlated with

task performance, and each marketers' competency dimension is positively correlated with relationship performance, there is positive correlation between task performance and relationship performance.

Table 1 The Correlation Analysis of Competency with Job Performance

		V1	V2	V3	V4	V5	V6	V7	V8
V1	Pearson Correlation	1	.491**	.341**	.493**	.488**	.373**	.353**	.245**
	Sig. (2-tailed)		.000	.000	.000	.000	.000	.000	.000
V2	Pearson Correlation	.491**	1	.247**	.390**	.458**	.204**	.314**	.269**
	Sig. (2-tailed)	.000		.000	.000	.000	.004	.000	.000

	Sig. (2-tailed)	.000	.000	.000	.000	.000	.000	.001	

** . Correlation is significant at the 0.01 level (2-tailed).

3.4 The regression analysis of marketers' competency with job performance

We explore the relationship of the six different marketers' competency dimensions with job performance with the method of hierarchical regression analysis, the results as shown in table 2.

Table 2 The Regression Analysis of Marketers' Competency with Job Performance

		Unstandardized Coefficients B	Standardized Coefficients Beta	t	Sig.	Adjusted R Square	F
V7	Constant	1.393		4.716	.000	.294	14.874
	V1	.017	.018	.228	.000		
	V2	.269	.102	1.415	.009		
	V3	.152	.158	.858	.392		
	V4	.242	.274	3.779	.000		
	V5	.037	.056	.753	.003		
	V6	.254	.276	3.992	.000

	V1	-.044	-.053	-.628	.531		
	V2	.185	.139	1.805	.003		
	V3	.281	.101	1.393	.005		
	V4	.134	.170	2.185	.030		
	V5	.012	.020	.257	.098		
	V6	.224	.272	3.673	.000		

3.5 Results analysis

1) It gets supported for hypothesis H1, marketers' competency can be divided six dimensions, management and decision ability, market development ability, interpersonal ability, communication skill, professional knowledge and personality traits.

Based on the analysis of the valid data, we find that the correlation and communality are good. The

cumulative variance contribution rate is 63.920%, so it is reasonable that divides the marketers' competency into six dimensions.

2) It gets supported for hypothesis H2, marketers' job performance can be divided into two factors, task performance and relationship performance.

The cumulative variance contribution rate of the two factors gets 63.920%, the variance contribution rate is high, it has good structure validity, so job performance can be divided into two dimensions.

3) It gets supported for hypothesis H3a, there is positive correlation between marketers' competency and task performance.

According to the correlation analysis between marketers' competency and task performance, the correlation coefficient of management and decision ability is 0.353, market development ability is 0.314, interpersonal ability is 0.287, communication ability is 0.447, professional knowledge is 0.340, personality traits is 0.430, they are all less than the level of 0.01, so the marketers' competency features has significant positive correlation with task performance.

4) It gets supported for hypothesis H3b, there is positive correlation between marketers' competency and relationship performance.

The correlation coefficient of management and decision ability with relationship performance is 0.245, market development ability is 0.269, interpersonal ability is 0.279, communication ability is 0.316, professional knowledge is 0.247, personality traits is 0.381, they are all less than the level of 0.01, so the marketers' competency features has significant positive correlation with relationship performance.

5) Market development ability has strong effect on task performance.

In the regression analysis between marketers' competency and task performance, the coefficient of management and decision ability is 0.017, market development ability is 0.269, communication ability is 0.242, professional knowledge is 0.037, personality traits is 0.254, they are all less than the level of 0.05, interpersonal ability does not enter into the regression equation. It can be seen that market development ability has the greatest influence on task performance, and the second is personality traits, the third is communication ability. The stronger the market development ability, the bigger the promotion of the products or services, thus it can promote task performance.

6) Interpersonal skill has strong effect on relationship performance.

The coefficient of market development ability in the regression analysis with relationship performance is 0.185, interpersonal ability is 0.281, communication ability is 0.134, personality traits is 0.224, management and decision ability and professional knowledge do not enter into the regression equation. From the regression equation coefficient, interpersonal ability and personality traits have stronger impact than others.

4 Conclusion

This study constructs the relationship model of marketers' competency with job performance, and analysis the proposed theoretical assumption with the 201 valid questionnaires with the methods of exploratory factor analysis, correlation analysis and regression analysis. The results show marketers' competency contains six dimensions, management and decision ability, market development ability, interpersonal ability, communication skill, professional knowledge and personality traits. Each dimension has significantly positive correlation with task performance, the coefficient of market development ability in the regression analysis is biggest that means it has the strongest effect on task performance. Each dimension has significantly positive correlation with relationship performance, interpersonal ability has strong influence on relationship performance. It also finds there is positive correlation between task performance and relationship performance, the correlation coefficient is 0.233.

This empirical research not only enriches the theory of the relationship between marketers' competency and job performance, but also provides reference for the practices of human resources management. However, there are many shortcomings in this paper. Samples are mainly come from Henan province of China, it hasn't been able to equal distribution in the provinces, so the results are more representative for developing provinces. Limited to the research conditions, the collected questionnaire is discriminating in different industry, not equal distribution, the final results may appear deviation. In this study, marketers that employed less than 3 years account for 79.6%, the number of senior marketers is relatively small, the following study need to improve the rate of senior marketers.

Meta Analysis of the Relationship Between Intellectual Capital and Organization Performance

Qin Hui, Wang Yuwei
College of Economy and Management,
ZheJiang University of Technology, Hangzhou, P.R.China, 310023
(E-mail: qinhui@zjut.edu.cn, 395852161@qq.com)

Abstract: How much does intellectual capital improve organization performance? Is there any discrepancy of their relationship among different situation? Furthermore, what kind of discrepancy? All of these have been the focus problem of the innovation management academia that the relationship between intellectual capital and organization performance. Based on the systematic search of relative empirical literature and sifting of data, this paper acquires 55 effect values and makes use of the method of Meta-analysis to a quantitative comprehensive analysis. The results show that there is a positive effect on organization performance made by intellectual capital. Moreover, it also offers a proof that SMEs' influence on organization is more significant than large size companies' as well as "after 2008" and "before 2008". Also, we find industry difference surprisingly make little impact on organization performance.

Key words: Meta-analysis; Intellectual capital; Organization performance; Situational variables

1 Introduction

Intellectual capital(IC) has long been the hot topic among management researchers for its well-known capability of predicting organization performance(OP).The fact is that traditional physical capital theory can't be regarded as an universal predictor for all the merits which are made by entity. However, it's hardly sufficient to offer us a good impulse if the so-called intellectual capital weren't important to the final performance. Above all, it seems a synthetical analysis for its "forecasting ability" is absolutely necessary.

Although the concept of IC has been put forward for more than 40 years, the influence and mechanism of "IC-OP" are still in suspense. For one thing, IC's definition and implication are still in a gradual progress so that a multi-dimensional argument is unavoidable^[1-3].For example, some scholars extend the IC's scope so that innovation's effect^[4,5] is also considered as a kind of IC

Another problem is that different studies are always based on different background and situation^[6]. Which always lead to a "narrow result". In addition ,it's also plausible for us to blame on an general instrument to measure the IC and OP.

Above all ,we try to integrate myraid qualitative and quantitative research ,extract latter's data to analyze the relationship of IC-OP and the moderating effect of situational and measurement factor to set an relatively precise commentary for these problems.

2 The Framework of IC-OP Based on Related Paper

Studies of IC differs in multifarious facets, from the basic definition to measurement .As the original point our paper start from ,we conclude them as follows.

2.1 Structure dimension

There exists discrepancy on division of IC's Structure dimension in different research for at least two reasons. First, Macro environment's evolution. provokes the changes of importance of factors. Also, on the other hand, different study perspective can usually be another reason for this phenomenon . Among these studies, dualism(human capital and structure capital) and trialistic theory (human capital ,structure capital, relation capital) are dominant perception on how IC can be constructed. Their argument largely focus on the issue that if relation capital ,as an indirect element should be treated individually, though most of their concepts of these three factors are basiclly similar.

2.2 Organization size

Almost all the research objects differ in their organization size. Based on general logic: the bigger the size an organization has the harder it needs to form an reasonable working system. This may lead to difference of the relation between IC and OP. So it's meaningful to analyze the size's influence on IC-OP.

2.3 Industry

Industries' influence on IC-OP seems obvious. High-tech industry always involves high attention on IC which is the core competence of every individual^[6-7]. In contrast, Low-tech industry may to a large extent depends on scale expansion. Though some papers try to prove this conclusion, at the overall level ,it's still an awayingstoring question

2.4 Business cycle

Business cycle may affect IC at many levels. During downturn, enterprise may tend to “Bourbonism” and austerity to retain the market position at strategic level. Also at Business Level, product line can possibly be shortened and narrowed down .This kind of expediency can change the IC’s effect on OP. Above all, we can conclude the basic model for IC-OP relationship as figure 1

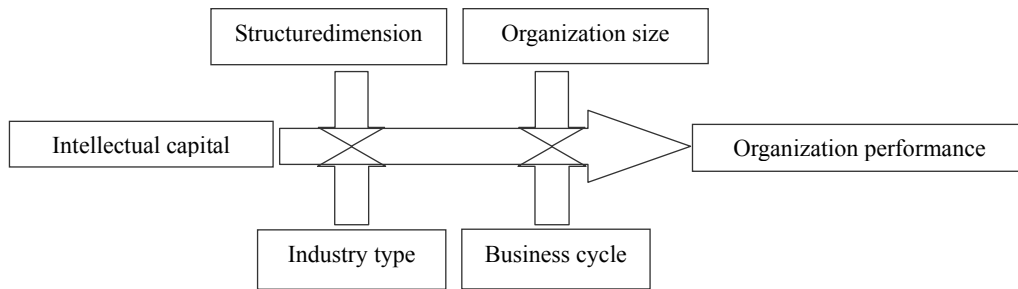

Figure 1 Conceptual Framework of IC-OP

3 Data and Methodology

First of all, we retrieve the literatures with the intellectual capital and the performance as keywords in Scopus, Elsevier Science, EBSCO, Springer Link and CNKI; more than 5000 search results are obtained. Secondly, select the literatures preliminary, the screening principle basically is to judge whether the title and abstract in conformity with the purpose of this study^[8-9]. Since the results of the literatures in literature database are often significantly in Meta analysis, those indistinctive results of literatures are not available, resulting in the publication bias in the Meta analysis. In order to minimize the publication bias in the Meta analysis, this study collect 151 alternative literatures from a large number of dissertations and unpublished papers through the above two stages. Next, based on the following principle to analyze and screen these literatures: first of all, must be empirical research; Second, intellectual capital has a direct effect on organizational performance, and has clear correlation effect value (or can be converted into the correlation coefficient r by calculation); third, different from other literatures of Meta analysis, for the purpose of representativeness, the literatures whose standard deviation of Fisher’ s Z value is too large (std>0.2) are not included in this paper. By filtering and sorting the literatures, there are 55 available samples for analysis eventually. Figure 2 is the distribution of effect value, the horizontal axis is the conversion of Fisher’ s Z effects values, the vertical axis is the standard deviations of Fisher’ s Z effect values.

Figure 2 The Distribution of Effect Value

From figure 2, the majority of effect value point inside the funnel graph. In addition, according to calculation of CMA, the fail-safe number reached 9836, which proves the wee probability of publication bias existing in this study.

In Meta analysis, heterogeneity inspection is very important. So-called heterogeneity is refers to the degree of difference between multiple independent researches, only the differences among multiple independent studies within a certain range, the statistic can be weighted combination. In Meta analysis, if there is heterogeneity between multiple independent studies, it's necessary to choose random effects model to analyze. Test results as shown in table 1.

Table 1 Overall Heterogeneity Test

Method	Synthetic Effect value	95%CI		Asymptotic value		Sample size
		Lower limit	Upper limit	Z value	P value	
Fix effect	0.380	0.367	0.393	51.960	0.000	55
Random effect	0.408	0.336	0.475	10.152	0.000	

Heterogeneity test: $Q=1515.932$ ($p=0.000$)

In table 1, the Q value of the data in this study by heterogeneity test is 1515.932 ($p < 0.001$), therefore, the random effects model will be used. In the random effects model, the comprehensive effect value is 0.408 ($p < 0.001$), which suggests that the correlation between the intellectual capital and organizational performance is 0.408 generally, and the following hypothesis test is meaningful.

4 Empirical Analysis

Based on the theoretical model, variables should be in the form of 0-1. In order to verify the above hypothesis put forward, first of all, classify and code the literatures, and then make the binary heterogeneity test, the results shown in the following table. There are 4 points can be found in table 2. First, the effect value of large size enterprise ($ES = 0.364$, $p < 0.364$) is lower than the value of small size ($ES = 0.416$, $p < 0.001$), and the heterogeneity inspection is significant ($Q = 8.215$, $p = 0.001$). Therefore, we can conclude that moderating effect on the relationship between intellectual capital and organization performance from small-scale enterprises is stronger than the effect from the large-scale enterprises. Secondly, the effect value of High-tech industry ($ES = 0.314$, $p < 0.314$) is lower than that of the non-high technology industry ($ES = 0.404$, $p < 0.001$). Thirdly, the effect value before 2008 ($ES = 0.359$, $p < 0.359$) is less than it after 2008 ($ES = 0.423$, $p < 0.001$). Fourth, the effect value of the dual structure ($ES = 0.431$, $p < 0.431$) is greater than the value of multiple structure ($ES = 0.326$, $p < 0.001$), so it can be inferred that the relationship between intellectual capital and organizational performance under the dual structure is stronger than under the multivariate structure circumstances.

Since the Meta heterogeneity test of the literatures in this study is significant, which showed that not only on the situational factors, there may be larger difference of the samples obtained in this study on the measurement factors. And these factors may affect the relationship between intellectual capital and organizational performance. We'll make a Meta regression analysis for further inspection. In the regression analysis of this paper, we code literatures in the form of 0-1 according to the requirements of control variables (the type of performance is classified into subjective performance or objective performance, while the dimensionality divided into two categories, Measurement item number falls into single and multi-dimension. At the same time, we set the value of literatures whose size can't be confirmed as 0.5, to make the comparison on the same sample size). In model 1, only add the type of performance, performance dimensions and performance measurement items number as three control variables, while, in the model 2, there are 4 hypothetical variables in addition. As shown in table 3.

It can be perceived from table 3 that the regression results of performance type and performance dimensions as control variables are not significant in model 1 ($p > 0.05$). Only the measurement item number factor is significant on the relationship between intellectual capital and organization performance. In model 2, further analysis can also found that the effects on organizational performance of large-scale enterprises and small enterprises are significantly different ($Coef = 0.202$, $p < 0.05$), which supports H2. Meanwhile, period also have a significant moderating effect ($Coef = 0.104$, $p < 0.1$), which supports the H4. In addition, the structure dimension number differences of the intellectual capital have certain moderating effect on the relationship between intellectual capital and organizational performance ($Coef = 0.240$, $p < 0.01$), which supports the H5. However, we also found that the differences between industries did not produce significant moderating efforts ($Coef = 0.069$, $p > 0.1$). Moreover, as a whole, although the model 1 and model 2 are both significant ($F1 = 13.105$, $F2 = 13.105$) but compared with model 1, whose moderating goodness of fit is 0.385, the number of model 2 is 0.716, it's a massive promotion. So the result of model 2 is the more worthwhile compared with model 1.

Table 2 Binary Heterogeneity Test

Variable type	Sample size	Synthetic Effect value	95%confidence interval		P value	Q value
			Lower limit	Upper limit		
Large size VS Small size						
Large size	33	0.364	0.349	0.379	0.000	
Small size	17	0.416	0.384	0.447	0.000	
Heterogeneity test					0.000	8.215
High-tech VS Low-tech						
High-tech industry	24	0.314	0.287	0.339	0.000	
Low-tech industry	31	0.404	0.389	0.419	0.000	
Heterogeneity test					0.000	36.376
Before 2008VS After2008						
Before 2008	27	0.359	0.343	0.375	0.000	
After2008	28	0.423	0.401	0.445	0.000	
Heterogeneity test					0.000	20.891
Dualistic VS Polyphyletic						
Dualistic structure	22	0.431	0.414	0.448	0.000	
Polyphyletic structure	33	0.326	0.307	0.345	0.000	
Heterogeneity test					0.000	63.409

Table 3 Meta Regression Analysis

	Model1		Model2

F	13.105		25.382	
Sig	0.000		0.000	

5 Conclusions

Though predecessors have proved IC has an positive effect on OP. However, due to specific research background, their commentary on the influence varies. we use META strategy to discuss the relative articles. Our conclusion as follows.

First of all, the overall correlation coefficient is 0.408(p<0.001), which means in general, IC indeed do good to OP. So in organization operation. manager should put sufficient attention on IC, balance IC and physical capital, strengthen import and cultivation of talents, improve incentive mechanism,adjust dynamics, adaptability and implementation of regime.

Secondly, small size companies has an significantly different effect on their OP with large size companies. IC works much better on improving the OP in small size enterprises . The reason for this phenomenon may depends. However, at least two kinds of effect can offer explanation for it. The first one is the scale effect that large size corporation has which may slow down their investigation on IC while for small size company, IC, in most of time, is the only path for their rapid growth. Design of experiment can also account for some part of the proposition.Large size companies' long term operation can form a great deal of tacit knowledge and principals which might affect without being caculated in IC.

Also, we roughly prove that in different business cycle, there exists discrepancy on IC's influences. The relationship "After 2008" is much more stronger than "before 2008". Basically The Result comes from two kinds of effect: eliminative effect and strengthening effect. The former helps to weed out the IC-lack enterprises while the latter promote the survivors' investment on IC.

Comparing with multi-dimension structure, we find IC could better predict the performance of companies in the situation of dual dimension. The point is dualism structure often ignore the effect of factors which produce indirect influence through but not in accordance with human capital and structure capital. Therefore, the tactic may lead to underestimate of IC's absolute value, thus exaggerate the final effect.

Finally, different from some empirical literature. The regression shows, industries' moderating effect is not as large as we think it should be. We believe the phenomenon is caused by both objective and subjective reason. To simplify the model, we roughly divide the whole into high-tech industry and low-tech industry. It might weaken the differentiating effect industry has. However if we take step further, the unavailability also convey to us an meaningful result which can probably be another reason: some industries which we traditionally treated as low-tech are gradually integrating some elements that originally owned by high-tech industries. Strategies like innovation of business model, professional refinement have also been taken by those so-called low-tech industries.

Abstract: Nowadays, with the rapid development of higher education, all kinds of new situation, new changes and new contradiction continually arising, the safety education and management of college students are facing new challenges. This article analyses the problems on the safety education and management of college students via reviewing the situation of it under new period. Then make an initial exploration on how to enhance it from the perspective of “Students Organization”.

Key words: Students’ Organization; Safety; Management

1 Introduction

In the new period, with the rapid development of economic society, the continuous deepening of the reform of higher education, the gradually extending of universities, and the constantly strengthens of students’ subject consciousness, as well as the value diversification, the safety education and management of college students are facing many new problems and challenges. For safety education and management of college students, many scholars put forward several solutions and methods from different perspectives, but most of them have neglected the importance of ‘students’ organization “-- the right-hand, in different degrees. Therefore we propose new ideas of college students’ safety education and management in new period from the perspective of “students’ organization”.

2 The Status and the Problems in Safety Education and Management of College Students

At present, although the universities have had a profound understanding of the new security situations, the new safety issues, as well as a variety of new factors that affect safety, and many efforts on the human and material resources have been invested, including safety awareness and safety education guidance. Yet, universities worksite accidents occur frequently, students are still lack of safety awareness, safety education is still far from satisfactory. Some scholars attributed the reason to the unclear content, invalid method and imperfect education system, and that the theory of safety education has been divorced from practice^[1-2]. we believe that the fundamental factor lies in students’ insufficient recognition, also that the students’ self consciousness has not been fully stimulated.

During the traditional process of safety education, as a manager, universities lack a broad understanding of the characteristic and the psychological demands of the management objects. Students have long been regarded as the object of the education management, they have to obey the rules negatively and passively. While the students in new period, most of who are after 90th, they are unusual, and sensitive to new things and new knowledge, and they have high intellectual curiosity^[3]. Therefore, in the education and management, conflicts and contradiction will inevitably happen between students and universities. For some of the university regulations, students are forced to obey at first, gradually becoming to ignore them, and finally turn into a negative confrontation, as a result of that, their self-consciousness are hard to inspired. According to the principle of internal and external cause of Marxism, the external cause must work through internal cause which is the students’ self-consciousness. Not until college students’ subject consciousness is awakened, the safety education and management are difficult to achieve its desired effects.

Currently, the university’s safety education and management team is relatively simple, and most of the universities mainly rely on school security guards and student staff, while few students involved in it. As a result, the weak power of the safety management is difficult to deal with the new challenges in the new period. If we lack communication and link during the management, universities can’t accurately master the safety situations of student group in dynamic, which result in low management efficiency.

3 The Position of Students’ Organizations

As the basis of building a harmonious university campus, students’ organization is the main

environment for college students' living and studying, which is built according to the relevant education regulations and the requirement of the education management, or established spontaneously by students' actual needs. Students' organization is a mass group with certain organization and management capabilities^[4]. Visibly, students' organization is the nature of mass organizations, with the flexibility, autonomy and other characteristics, it also has the function of self-education, self-management as well as supporting school education.

The scoping for students' organizations is different in broad and narrow senses. Broadly, it is composed by student party, mission organization, student union and graduate students council, also includes the class committee and student associations. In a narrow sense, it refers to the student union and student associations^[5]. What referred to in the article is the broad sense.

4 The Function of Students' Organizations in Safety Education and Management of College Students

College students' organization as a student mass group under the leadership of the Party, aims at achieving students' self-education, self-management and self-service. College students' organization is the backbone of strengthening and improving the students' ideological and political education as well as the right-hand of the management team in universities. Even more important, College students' organization as a bridge between universities and students, plays a crucial role in the student work, also, in the college students' safety education and management.

4.1 Education and guidance

Students' organization as a subsystem in the higher education system, its core goal is to achieve education function.

The first function is to educate the members. Students' organization as a mass organization, not only its members can accept the concepts, the culture, the atmosphere and other aspects of the organization, but also function properly like wind into the heart via the interaction between the members.

Secondly, as a student practice site, the students' organization is the main carrier of cultivating the correct security concept. By the safety education activities, the connection of theory and practice can be achieved to a large extent, which helps students to digest safety knowledge via extracurricular exercise, thereby enhancing their safety consciousness and security capabilities.

In addition, the organization is composed of student representatives who are with advanced natures. They can play an exemplary role in helping students improve their consciousness in carrying out the universities' safety management regulations and measures, and helping them strengthen their safety awareness.

4.2 Communication and coordination

On the one hand, students' organizations act as the messengers to bridge the universities and students. They protect the interests of the school and promotes school's development. Meanwhile, they play important role in representing and safeguarding the students' interest, stabilizing the campus security, and ensuring student's benefits. They come from students, go round to the students, they can collect information immediately and accurately and reflect to the executives how the students thought. In this way, activities about safety education would be conducted more closely, pertinently and effectively.

On the other hand, students' organizations are the friends of the students. They are able to collect and sort out the responses and needs of the students, discover potential threats timely, benefit for the efficient conduction of all kinds of activities, the reinforcement of the security alarm efficiency, the protection of students' interests, and the stabilization of the security in universities.

4.3 Auxiliary management

In recent years, with the rapid development of higher education, university enrollment has been sharply raised, college students become more and more. As a result, it is difficult to achieve an all-round, high-efficient and overall management by the limited human resources of universities. Therefore, in the new period, safety education and management have to be carried out with the help of satisfactory assistance of students' organizations. On the one hand, they can help executives deal with daily chores and ensure universities safety education and management work steadily; additionally, according to students' quality development mechanism theory, universities actively absorb students' organizations involving in the management activities can turn negative factors into positive ones, and form the resultant of forces, thus achieve an benign interaction between schools and students, so as to promote

efficiency of safety education and management.

5 Safety Education and Management of College Students Based on Students' Organizations

Students' organizations involved in safety education and management is an important entry point of university governance and democracy in harmony. College students' organizations play long-term role in the maintenance of stability, it needs to proceed from the following aspects :Ideological foundation level - first, the students' organization must build core values to lay the ideological foundation ;Angle design level - the students' organization play the role of Party branch, league branch, the student union, and other organizations at the same time. They give full play to the advantages of their organizations, to strengthen the students' main part role, through different organization forms, the students can improve their own quality duiring the participation; Behavior level-Sundry students' organization should encourage students to participate in a characteristic behavior patterns, and stimulate students' interest and potential of self-management and self-education.

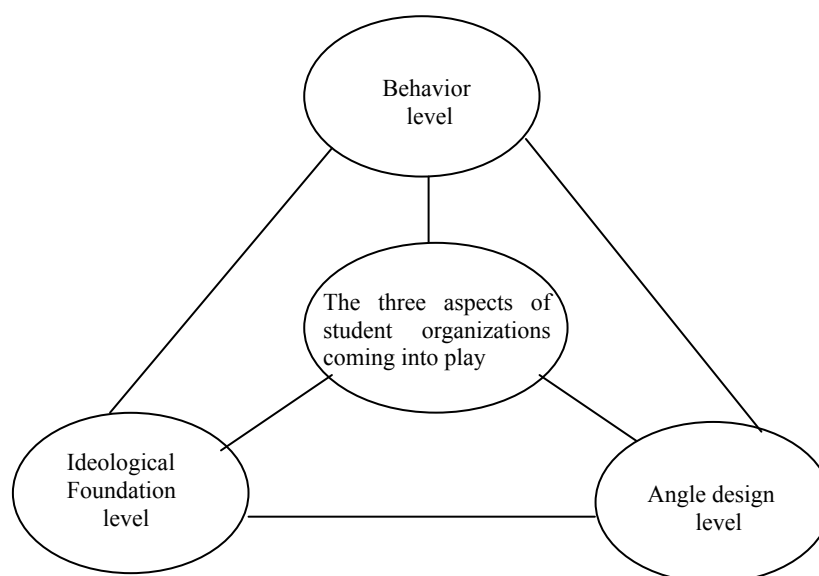

Figure 1 The Several Aspects of Students' Organizations Playing A Role in the College Students' Safety Education and Management

5.1 Raise awareness, enhance the dominant position of students' organizations

The crux of the campus safety and culture construction lies in the positive school-to-student interaction, which can be used to build up an interactive platform with students' organizations, so as to realize the maximization of management benefits^[6]. In this regard, university executives must recognize the significance of students' behavioral expression and the information transmission of students' organizations. Currently, student union and associations, which now are the most universal carriers of students' participation in school management, need to be consolidated. In addition, universities should build and expand new students' organizations, and guarantee the material provision and financial support for their activities.

University executives are required to recognize the significance of students' participation in management, and give students the executive right, provide more opportunities on the platform of school's website and BBS, to motivate the students to participate and truly promote the dominant position of students' organizations in the safety management.

5.2 Strengthen guidance, let students' organizations play a dominant feature

Students' organization, as a mass organization,, which core and key is students backbone, who act as the bond connecting universities safety department with students. For these students, their ideological quality and working ability directly influent the image and function of the organization. However, in the new period, due to the impact of multiple cultural trend of thoughts, many students' values and outlook on life have become increasingly complicated, and so it is the same with students in charge. Problems

like a lack of security sense, little passion for work and emergence of bureaucracy have appeared. Hence, when students' organizations are endowed with justifiable and appropriate autonomy, schools should allocate professional teachers to them for proper instruction and management, and truly implement "to leave alone with trust, but not to let go unchecked". Under the circumstance of staying in the right general orientation, the school should encourage students to be innovative, hold all-round, multi-angle and three-dimensional activities of safety education and make full use of the college students' leading position in safety education and management.

5.3 Improve the management system, strengthen self-construction of students' organizations

When drawing great attention of the university executives, students' organizations should focus more on their own development and improvement of the systems, so as to guarantee their efficient and harmonious development. On the one hand, they should perfect the system of safety education and management, such as provide regular trainings on safety knowledge, keep reinforce members' safety awareness and promote their sense of responsibility and mission, in order to act as a model for students.

On the other hand, information communicative system must be built. Students' organization, should take an initiative in investigating and collecting students' ideas and suggestions for the universities security, reporting nearby potential safety hazards in time, calling together student representatives to attend regular conferences, they should fully fulfill their responsibility and obligation by proactively reflecting problems to the relative departments in safety education and management and offering advice.

6 Conclusions

In short, college students' organizations for college students is a reliable platform for self-management, self-education, self-service, they are important and effective ways for the school safety education and management of work. Students' participation embodies the democracy of education and management, and provides opportunities for students to taste the significance of safety management in practice, and further reinforce the safety awareness and practical skills, which is paramount for promoting college students' comprehensive quality and building a harmonious university campus.

Imitation & Innovation in Emerging Countries: A Conceptual Framework for Analysis

Nguyen Huu Phuc

Graduate School of Innovation and Technology Management, Yamaguchi University,

Tokiwadai 2-16-1, Ube City, Yamaguchi Prefecture, 755-8611, Japan.

(E-mail: phuc@yamaguchi-u.ac.jp)

Abstract: The ultimate aims of our research are to i) offer a technical description of imitation behavior, ii) modelize imitation with other related factors to present an overall model where all important factors can be measurable, and iii) utilize the model to measure the impacts of imitation. Therefore, understanding the concept of imitation and other related concepts in order to properly characterize these concepts, and then building a conceptual model are the first steps toward achieving this aim. This paper will focus on i) the review of the literature on imitation and its limitation, ii) the understanding of the relationship between imitation and other related concepts, and iii) the resultant suggestions on a conceptual framework for analysis.

Keyword: Imitation; Innovation; Copycat; Technology Transfer

1 Introduction

Innovation is without doubt an influential factor that is crucial to enterprise survival and growth. It contributes an authoritative power of monopoly that generates profits until competitors show up. Having said that, however, in fact, nearly 98% of the value of innovation goes to imitators instead of innovators (Shenkar 2010).

Imitation in this paper refers to the intentional copying of the innovator (or pioneer, market leader)'s existing technology, design or function as well as the pioneer's organizational practices, business models or other strategies. Illegal forms of imitation, such as piracy and counterfeiting are not part of our paper.

If one takes a look at the leading player in many sectors, one will be surprised to find that the leading player is not the pioneer but the able and creative imitator. Visa, Master Card, and American Express copied what Diners Club once pioneered in credit card business. After a long period of creative imitation through global partnerships, China's Huawei is today the largest telecommunications equipment, and Brazil's Embraer is the third largest global aircraft company. The majority of today's giants have grown up from creative imitators.

Moreover, in developing countries, most economic development in the catching up processes started with imitative innovation. In emerging countries, imitative innovation is a topic of great practical and policy interest.

From legal perspective, imitation itself does not necessarily imply a negative behavior or illegal infringement. There are legal as well as illegal imitation. Japan and Korea obtained their rapid industrialization through inspiring many European and America enterprises' advanced technologies and business practices. All of these innovative imitations thus do not necessarily involve illegal patent infringements or counterfeits. In Korea, the majority of large local pharmaceutical and cosmetic companies have evolved from small firms. They first started as business traders importing drugs, then gradually participating in pharmaceutical manufacturing process through imitating from the simplest steps like packing the finished drugs, next importing chemical materials to produce drugs, and finally manufacturing the pharmaceutical materials. Their growth in size, technological skills and capabilities has been expanded through their imitation process. Their imitation strategy has changed and is thus optimized to their internal condition and external environment over time.

Despite the fact that imitators often overshadow innovators, imitation is unjustly neglected in the academic literature. It receives inadequate attention on most economics and business studies.

It might be because that we have been educated from a young age to consider imitation "undignified and objectionable" (Shenkar 2010). In companies, the word "imitation" has been treated as a taboo by both executives and employees. Consequently, imitation is not an available option for enterprise strategy or it is conducted tacitly in the dark without properly strategic management.

Furthermore, even if enterprises embrace imitation and treat it as important as innovation, it is not easy to make it successful. The imitation strategy tends to backfire, for instance, when imitators are attracted to the observable elements of an innovation and fail to learn and copy what makes it successful.

In addition, in many cases, what worked with the innovators may not work with the imitators. On top of that, imitation itself does cost a lot of money, time and efforts. To successfully compete with the innovators, understanding the “true” imitation and being able to develop capabilities to conduct imitation strategies are crucial to imitators.

In order to understand the mechanism of imitation, this paper focuses on building a conceptual framework for analyzing imitation. Our conceptual framework is primarily concerned with five questions.

Firstly, how should we categorize and classify the different aspects of imitation? This part will introduce some of the key concepts used in defining, categorizing and classifying imitation. It also gives a broad overview of similarities and differences between imitation and innovation, learning and knowledge accumulation, and technology transfer.

Secondly, how does an imitation look like in an imitation game? We will examine some findings in the literature regarding imitation strategy as well as the strategic players.

Thirdly, how do customers react to imitation? This part examines consumer response to imitation. A proper understanding of how customers react to imitation requires us to understand a broader range of theories of consumption. We then draw out the connections between these theories of consumption and the evolution of imitation into innovation.

Fourthly, which is the optimal choice for a company, choosing between two strategies, that is, engages in R&D or abstains from own R&D and imitate the outcomes of innovators? We discuss the relationship between imitation, innovation and intellectual property protection. The basic premise is that imitation is not only as critical as innovation to business but also is vital to the effective development of innovation itself.

Fifthly, what effects does imitation have on the economy as a whole? This can be analyzed at various levels. We look at the implications of imitation in the economic growth of emerging countries as well as examine the inter-relationship between imitation, competitiveness and market structure. We also take a brief look at the role of imitation supporting a sustainable economy. This part reveals the two sides of imitation. It can sometimes be a threat to sustainability but can also - perhaps unexpectedly - help to achieve sustainability.

2 Review of Literature

2.1 Definition of imitation

Imitation is the intentional copying of the innovator (or pioneer, market leader)'s existing technology, design or function as well as the pioneer's organizational practices, business models or other strategies. Imitation is thus an imitator's optimal strategy that is a resultant dynamic equilibrium satisfying firm internal condition, market external environment, and customer demand.

2.2 Different forms of imitation

(1) From the perspective of innovativeness:

- Technological imitation: There are two distinct levels of imitations according to how the imitated products or services are different from the originals.

- ◇ Pure imitations (also duplicative imitations): legal copies of the original product. Most of them are third party' products like lithium batteries for a Nikon camera or numerous YouTube-like websites where users can upload, watch, and share video clips.

- ◇ Innovative imitations (also creative imitations): various kinds of modifications (or improvements) from the originals by designing differently, adding new functions, improving product performance, using different manufacturing processes and changing materials. Microsoft Excel is an innovative imitation over its pioneering product Lotus 123. Innovative imitations can be realized through several ways, for instance, reverse engineering, patent purchase, outsourcing (purchasing from open market), joint product development and imitation with adjustment for the local needs.

- Organizational imitation: Organizational imitation consciously replicate organizational procedures, business models or strategies. It can be also categorized into pure or innovative level like technological imitation.

(2) From the perspective of strategicness:

- ◇ Exploitative imitation (from an imitator): the imitator provides an imitation with more improvements or at a more competitive price. It happens when market barrier is low or is hard to establish. For example, take a look at digital camera that was first commercially marketed by Fuji Camera and now has been continuously improved by many other makers.

◇ Incompatible imitation (from an imitator): the imitator's counter-strategy against the innovation by introducing similar product but incompatible with the existing originals, for instance, an incompatible imitation of Apple iPad is Samsung Nexus. This strategy is particularly adopted when there is the existence of network effects, and thus tends to lead to a war of de facto standard.

◇ Proliferative imitation (from an innovator): instead of offering one product, the firm imitates its own originals and provides a lineup of various imitations with slightly different characters and prices. The firm benefits from the price discrimination. It is also a preemptive defense against any possible market entrance by curtailing competitor's opportunity and profitability.

◇ Open imitation (from an innovator): one partner agrees to let the other partner use, for example, a particular technology that was strategically selected under specified conditions.

2.3 Relationship between Imitation and Innovation and Intellectual Property Protection

In the economic literature on innovation, there are two contradictory results regarding the relationship between innovation and imitation. One starting with the works of Schumpeter (Schumpeter 1934, Schumpeter 1942) argues that imitation deters innovation as it discourages efforts of innovators in creative innovation. As a result, imitation has negative impacts on innovation, and strong protection of intellectual property is the prerequisite to promote innovative activities in R&D (Arora and Gambardella 1994; Gallini and Scotchmer 2002; Gans and Stern 2003; Gan et al. 2008). On the other hand, other studies (Aghion et al. 2001; Bessen and Maskin 2009; Zhou 2009) show that the pressure of being imitated stimulates the incumbents' innovative endeavors. Therefore, intellectual property protection can hinder rather encourage the innovative activities.

Regarding the protection of intellectual property, there are two approaches. One is the *formal* method having intellectual property to acquire some kinds of official acknowledgement, for example, patents, registration of design, trademarks, and copyrights. Making the IP public, however, also induces the competitors to imitate, particularly in countries where the IP law enforcement is still weak. The other approach is *informal* but strategic, that is, i) wise use of lead-time, ii) ensuring product/process/design complexity, iii) confidentiality agreements, and iv) other strategies for secrecy. Literature has shown that the informal strategic approach offers much better protection effectiveness for the IP regardless of firm size (with exceptions found in chemical and pharmaceutical industries).

2.4 Innovative Imitation, Incremental Innovation, Technology Transfer

Innovation expresses a strong implication of invention – the process that the firm involves the development of a radically new product. There are two types of innovations according to the impact of the innovation on the competencies of established incumbents: incremental innovation and radical innovations.

Incremental innovation implies the improvements that are made steadily to a product or process without changing the fundamental characteristics of that product or process. Established incumbents are able to respond effectively to these incremental innovations from competitors.

Radical innovation refers to the fundamental improvements that transform the product features. It seriously threatens the market power of established incumbents and deteriorates their competencies. Established incumbents find it hard to respond to these radical innovations. Incremental innovation occurs steadily along a product life while radical innovation happens very occasionally, but it is disruptive to the incumbent products, for instance, CD-R disks that displaced the 2.5-inch floppy disks as a storage media in personal computers.

In general, innovative imitation is not the same as incremental innovation. Innovative imitation is a superset of incremental innovation. Innovative imitation encompasses not only improvements made to the originals, but also innovative degenerations, for example, that may abate the originals' functionality but reduce the product price. The innovative degeneration does not contribute any technological improvements, but by, for example, wisely adjusting the production process or using inferior materials, the imitator can offer a downgrade but useful product at a much cheaper price. Without a clear distinction between the two concepts, many may barely tell innovative imitation from incremental innovation. This ambiguity may give a wrong impression that the study of incremental innovation covers the other and thus makes the study of innovative imitation look less important. In this paper, we suggest two new definitions: *inferior* imitation and *superior* imitation. The latter is incremental innovation itself while the former refers to the innovative degenerations.

Technology transfer is a deliberate activity of a technology patent holder to transfer technological knowledge to an imitator. It is considered to be beneficial to both sides as imitators can gain new technology or update their existing technological base while technology patent holders can earn license fee or exploit the advantages of the imitators. For instance, using the natural and human resources of

imitators, expanding the patent holder's market or forming a favorable technology standard. From an imitator's view, it is a technological imitation with the support from the innovator.

Technology transfer occurs in the manufacturing sector, whereas in the service sector, there is a similar imitation form that is called "franchise".

2.5 Players in an imitation game and their strategic action

According to Schnaars (Schnaars 1994), "the concept of imitation is related to, but distinct from, the concept of later market entry". Therefore, an innovator may not be a pioneer, but a later entrant. Likewise, an imitator may beat the innovator to be a pioneer in the market instead of being a later entrant. Schnaars adds the "time" factor that is the timing of entering the market into the imitation game between innovator and imitator.

Shenkar (Shenkar 2010) expands this thinking by integrating the "space" factor into the game. It results in three strategic types of imitators: "the *pioneer importer*, an imitator which is the pioneer in another place (another country, industry, or product market); the *fast second*, which is a rapid mover arriving quickly after an innovator or pioneer; and the *come from behind*, a late entrant who typically relies on pronounced differentiating factors." (Shenkar 2010).

Additionally, in most markets, we can identify a core of firms that are persistent innovators or persistent imitators while other firms are either occasional innovators or imitators.

2.6 Imitation Strategy

It is generally accepted that a successful imitation strategy is contingent on various internal capabilities. Previous literature (Luo, Sun and Wang 2011; Yoon 1998; Cohen and Levinthal 1989, Cuervo-Cazura and Genc 2008, Lieberman and Asaba, 2006) indicates five capabilities as follows:

- ✧ Combinative capability: skillfully combine and integrate the imitator's own resources with outside technologies.

- ✧ Absorptive capability: speedily evaluate, learn, apply and enhance new knowledge.

- ✧ Networking capability: foster reliable formal and informal network.

- ✧ Hardship-surviving capability: a combination of entrepreneurship with persistence and flexibility to overcome economic, political and institutional uncertainty.

- ✧ Intelligence capability: ability to detect, collect, and evaluate information regarding imitation-relevant PEST, market and industry intelligence.

The ultimate goal of these capabilities is to acquire and enhance three competitive advantages:

- ✧ Cost advantage: to deliver suitable technology at a low cost.

- ✧ Speed advantage: fast imitation is the key to succeed when confronting the innovators and other competitive imitators.

- ✧ Channel advantage: standalone imitators will never succeed with any imitation strategy.

Regarding the relationship between imitation and market competition, the literature on innovation shows an ambiguous result. To grasp the overall relationship between three factors: imitation – innovation – market competition, the reasons are sequenced as follows:

Firstly, market competition means market pressure that is inversely proportional to the degree of market concentration. Market competition can also be measured by the degree of product differentiation, that is, an increase in the homogeneity of products (i.e. lower degree of product differentiation) implies that market competition is more intensive.

Secondly, the effect of market competition on incentives for innovation is inconclusive. There are three conflicting results. One is that market pressure fosters innovation as a decrease in market concentration spoils the innovative spirits (Dasgupta and Stiglitz 1980; Geroski 1990; Blundell et al. 1999). On the other hand, several researchers argue that more intensive market competition discourages incentives for innovation, as innovative advantages are temporary (Arrow 1962; Futia 1980; Gilbert and Newbery 1982; Reinganum 1983; Zhou 2009). Therefore, market concentration vitalizes firms' innovation as monopoly power of larger firms proved a major accelerator of technological progress (Henderson and Cockburn 1996; Cefis 2003). These controversial arguments gave a support that the relationship between market competition and innovation may not be monotonic. For instance, Aghion et al. (2005) shows that the relationship is an inverted-U shape. At low and high level of market competition, the incentive for innovation is low, whereas firms will increase efforts in innovation when they are in a medium level of competition. Again to make the issue more complicated, Boone (2000) indicates that the innovative efforts depend on not only the market competition but also the innovative capability of the firms: less efficient firms tend to increase innovative activities when competition is weak. Conversely, firms that are more efficient will boost their investment in R&D when competition becomes more intensive.

Finally, as mentioned in the previous part, there are contradictory results regarding the bi-directional relationship between imitation and innovation: it can be positive or negative. Moreover, Braguinsky et al. (2007) reveals that the relationship between imitation and innovation is also contingent on other factors like the maturity of the industry itself or the characteristics of the market. When the industry is still in its early stage and small, innovators as well as incumbents do not have incentives to prevent imitation. However, as the industry keeps growing, imitation will deteriorate innovative effort.

As a result, further work needs to be done to understand the complex interrelationship between market competition and imitation.

3 Conventional Methodologies for Analyzing Imitation and Their Limitations

Recently, there have been an increasing number of studies on imitation. According to their analysis approach, the majority can be categorized into two types:

(1) Business management approach: It often uses survey data to conduct empirical analysis (Lee and Zhou 2012; Luo, Sun and Wang 2011; Zhou 2006). A distinctive tendency of this kind of study is the research context originates in China. Foreign investment has poured into China to seize the huge opportunities in this fast-growing market. The influx of foreign firms brings new technologies as well as creates competition in China market. Consequently, firms in China have to rely on innovation orientations to survive the competition. The initial and realistic step of many firms is to imitate the innovators. This phenomenon provides rich material for studying imitation.

This approach without doubt offers several very useful and applicable results. However, due to the nature of latent analysis, there is still considerable ambiguity with regard to the design of the survey which is the foundation of the analysis. The empirical analysis was built on previous qualitative research of Schnaars (1994) in which three questions are set up to measure pure imitation, similarly another three questions to measure creative imitation. As discussed above, not only imitation type but also the types of imitators as well as the characteristics of the industry should be included in the survey. Moreover, this survey method also suffers from uncertainty that with only three answers from an imitator, is it possible that one can identify and measure pure imitation or creative imitation?

(2) Economics approach: This approach is developed from two distinct perspectives: Macroeconomics (the North-South model of growth and trade) and Microeconomics (the Two-stage Cournot model).

Theoretical results are beautifully constructed and very instructive. Nevertheless, because of the characteristics of the models, the main limitation is that the analysis cannot be conducted with empirical data.

4 Discussion toward A Conceptual Framework to Analyze Imitation

This part will be quite short, but that does not imply its content is unimportant. Rather it is because parts of discussion have been mentioned earlier in the previous parts. Issues that are related to the characterization of possible variables and parameters will be discussed as follows.

Firstly, the literature on imitation would seem to omit an important factor, that is, *consumers*. Products, either imitations or innovations, eventually will be evaluated by customers. The response of customers will decisively determine the success of that imitation. In general, the response may be active or passive with regard to an imitation. It is not clear about the effects of consumer types on imitated products. It may vary over the consumer segmentations (or customer attributes), place of living, or product life cycle. Additionally, the aggregate demand, network effects or sunk costs are also important factors. Moreover, in theory, there are several types of consumers such as Douglas, Veblen, Marshall, and Galbraith consumers, or utility-based economic consumers.

Secondly, the behavior of imitation would seem to be a process of absorbing and applying new knowledge originated by an innovator. As for the imitator, the knowledge that he imitates is the subset of the knowledge of the innovator. However, it may be either completely new to the imitator (i.e. it has the empty intersection with the imitator's own resource), or partly overlapped. As mentioned earlier, one of the distinct differences between imitators and innovators is that while the innovator tends to enhance its technology by their own and keep it secret from others, the imitator exploits its network (or channels) to learn and apply the technology. It implies that i) the knowledge once the imitator obtained will be more versatile, and ii) the existence of spillover effects over its network. It is a hint for an imitator to succeed in its imitation strategy as well as for a counter-strategy of an innovator.

In sum, an ideal model for imitation analysis is proposed to take the following aspects into

consideration:

- ✧ Types of imitation
- ✧ Types of imitators
- ✧ Types of consumers and their response to imitation
- ✧ Characteristics of the innovator
- ✧ Characteristics of the industry include but not limited to: market competition (or market concentration, or product differentiation), the industry maturity, innovation diffusion degree, intellectual property protection, and networkability.

- ✧ Capabilities required for an imitation strategy

Hence, analysis results will include an imitator's optimal strategy that is a resultant dynamic equilibrium satisfying firm internal condition, market external environment, and customer demand.

5 Conclusion

This paper conducted a review of the literature on imitation and the relationship between imitation and other related concepts. We also explained some limitations in the literature. Our study provided some suggestions on a conceptual framework for analysis. However, our work clearly has its own limitations. The current study was limited to offering academic suggestions. Despite this, we believe this study has gone some way towards enhancing our understanding of imitation. Future work will focus on i) offering a technical description of imitation behavior, ii) modeling imitation with other related factors to present an overall model where all important factors can be measurable, and iii) utilizing the model to measure the impacts of imitation.

Research on Inner Circulation Mechanism of Security Housing

Han Fang, Diao Zhaofeng

School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070

(E-mail: han_whut@163.com, diaozf@163.com)

Abstract: Housing is basic human rights and claims for survival and development. Housing issues, particularly low-income housing security issue has been highly concerned by governments around the world. As to the presence of problems like imbalance between supply and demand and exit difficulty, this paper proposed a new housing security mode that suggests supply subsidy changing to demand subsidy for security housing and rent and sell combined pattern changing to mainly rent pattern, and we analyzed different types of security housing problems in rent subsidy and title transfer of property, and ultimately established an inner circulation mechanism for security housing in China and achieved sustainable operation of security housing sequentially.

Key words: Security housing; Inner circulation; Operating mechanism

1 Introduction

Housing plays an important role in the process of industrialization and urbanization, and it has become a consuming hot spot in the upgrade process of demand in urban consumption. The essence of housing security problem is the contradiction between affordability of urban low-income households and housing price with suitable housing standards. Countries worldwide have developed a diverse housing security system according to their own national conditions to ease the housing contradiction between low-income families and maintain social stability. Housing security has gradually become an important part in social security system.

In recent years, the Chinese government continued to increase security housing investment and expand the scale of construction of security housing, but as more and more migrants and newly workers are brought into the housing security system, and the practical application of the exiting mechanism for security housing faces many difficulties, there is still a giant gap between the supply and the demand of China's security housing. In the face of the serious imbalance between supply and demand in security housing in our country, this paper starts from the change in the pattern of housing security, presents the recycling and dynamic flow for existing security housing, and builds inner circulation mechanism for security housing.

Currently, scholars have proceed many useful explorations in housing security pattern and sustainable operation of security housing, and most of them focus on improving utilization efficiency of security housing resource and improving the exit mechanism and so on. American scholar Arthur O'Sullivan (2007) advocated the adoption of cash subsidies in lieu of direct housing subsidies, and thus to improve the utilization efficiency of housing guarantee fund^[1]. According to the development process of U.S. housing security system, Olsen Edgar' O (2001), summarized the housing security system in four basic forms, and his research data shows that direct subsidy based on leasing is the most cost efficient housing security^[2]. Cao Xing (2006) advocated that the government should increase the weight in exit mechanism and circulation mechanism of security housing^[3].

2 Necessary Conditions for the Operating of Inner Circulation of Security Housing

2.1 Subsidy pattern transfers to demand subsidy

Security housing subsidy is an effective measure of regulation and intervention for government in the housing market, and can be summed up into two types, one is that the government directly intervenes housing supply and inputs financial subsidies to producers, which is called supply subsidies or "bricks and mortar subsidies"; another one mainly refers to that the government provides financial subsidies to the housing demanders in the form of cash or direct tax relief, which is called the demand subsidy or "poll subsidy"^[4].

Overall, despite that the two kinds of subsidies often co-exist in the actual operation, most countries in the world that implementing housing security policies have experienced or are experiencing the transition from demand subsidy to supply subsidy, for the demand subsidy have his incomparable advantage. Firstly, the demand subsidy achieved an organic combination of market resources allocation

and market regulation mechanism, which avoided direct intervention in the housing market. Secondly, housing subsidies directly reaches to housing needed families, which reduced the risk of the real estate developers might take the subsidy funds and reduced the regulation difficulty and cost of the government. Finally, it is conducive to the formation of withdrawal mechanism. The government can make changes in the amount of subsidies or even eliminate the subsidies to encourage residents to buy their own house when the resident income changes, which would simplify the exit mechanism and reduce management cost.

It can be seen that demand subsidies are more efficient security housing subsidies, and it will play a positive role in promoting the development of urban real estate. However, throughout the whole evolution history of housing security system in major western countries, the government often participates in housing construction directly in the period of serious housing shortage in order to ease the housing shortage pressure in a short term; and when housing supply and demand become more reasonable, the government generally adopts a currency subsidy way to meet the housing needs of low-income families. Concerning the current housing situation, China's housing subsidies should not abandon supply subsidies and change into demand subsidies totally or blindly, rather than determine ways of housing security subsidies by stages and local conditions according to housing development, and gradually transfer to the demand subsidies pattern.

2.2 Supply pattern transfer to rent

At the beginning of implement of China's security housing, it was artificially divided into low-rent housing and affordable housing, and low-rent housing is only for rent and not for sell. While affordable housing the opposite, and there are still public rental housing and price limited housing. In general, China's security housing has combined rent and sell, and different security patterns works relatively independently.

The way of being mainly for sale of affordable housing supply is consistent with the orientation of corporate development strategy of financial oriented affordable housing developers, however, the rigid way of only sell is incompatible with the dynamic changes of secured groups, often accompanied by the withdrawal mechanism, the complex of title transfer and ill-defined value-added benefits and other issues, is not conducive to the circulation of affordable housing and recycling of support housing resources, resulting in the loss of security housing benefits.

By contrast, the rent-mainly way of security housing supply has its unique advantages. First of all, it can effectively avoid the housing security resources been purchased or use by non-security households, it can alleviate the supply and demand of security housing, and reduce the government's financial burden on housing security. Secondly, excluding part of the purchasers those who regard the security housing as an investment, the filtering effect produced by non property transfer filtered out the families with no need for security housing automatically. Finally, it is facilitate for the government conduct dynamic management to those secured families and ensure their in-time withdrawal. Once the lease tenants do not meet the security conditions, as a property owner, regulatory agencies can force households to move out of the security house to protect the formation of exit mechanism according to compelling force of laws and regulations.

An overall consideration of the pros and cons of mainly rent supplying pattern of the security housing, distribution pattern of China's security housing should be combined with rent and sell and most rent to meet the dynamic needs of housing security groups. With the transfer of property rights of early-sold affordable housing and the improvement of our housing security pattern, we can gradually reduce the proportion of affordable housing for sale, achieve a unified operational mechanism of all kinds of security housing, and thus reduce the management difficulties of security housing.

3 Build Inner Circulation Mechanism for Security Housing

Compared with developing new security housing to solve the supply problem of China's security housing, the recycling and dynamic flow of existing security housing and build inner circulation mechanism for security housing may be the key point to solve the problem at all. Inner circulation mechanism for security housing is a closed circulation of affordable housing in the secured groups, the link between the exit of families beyond protection and access of families newly need for housing, from the regime perspective, affordable housing is always used to solve housing problems of low-income families, the welfare nature of security housing remain unchanged in order to achieve sustainable operation of security housing, as shown in Figure 1. The transition of security housing subsidies and changes in the way of supply are the foundations to build the inner circulation mechanism for security

housing, from application, access, distribution, regulatory to exit are the whole processes of the operating mechanism cycle, in which exit mechanism is the key factor to the formation of the inner circulation.

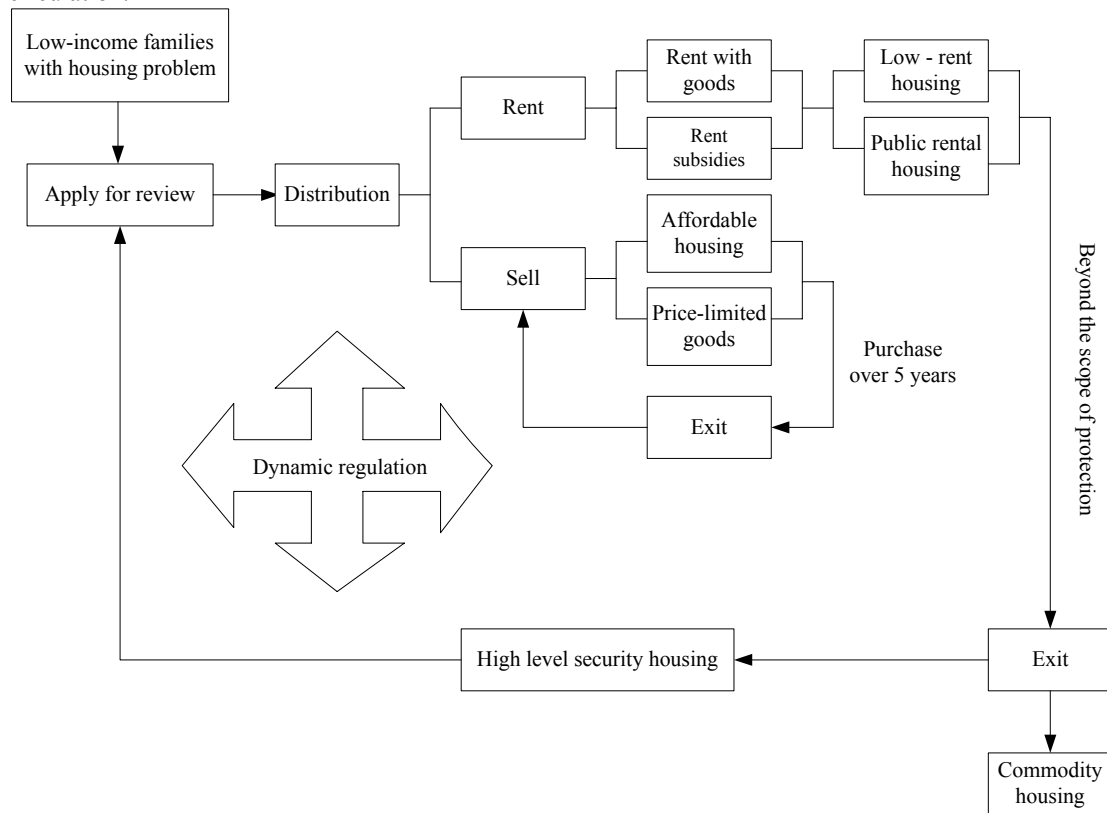

Figure 1 Inner Circulation Mechanism for Security Housing

3.1 Rental subsidies of security housing that mainly for rent

Rent with goods and rental subsidies are two main types of subsidies of security housing in China. As the housing authority’s management and regulations of exit mechanism for security housing are still not perfect, punitive measures are not sufficiently clear and legal mandatory can’t be bring into full play, thus make the security house that rent with goods much difficult to reclaim when it is beyond guarantee period or the living household is beyond the scope of insurance coverage, which takes government a lot of regulatory costs.

Compared with the problems caused by the rent-with-goods style to the exit mechanism of security housing, rent-subsidized security is more favorable to the formation of it, and can make changes in the amount of subsidies when resident income changes; the rental subsidies can be canceled once if the lease contract expires and without re-apply or the family no longer meets the lease conditions after audit, and thus makes rental price of security housing consistent with the market price, thereby encouraging the resident to rent or purchase housing all by themselves and simplify exit mechanism and reduce management costs.

3.2 Property transfer of security housing that mainly for sale

The operation of China’s affordable housing adopted a sales-oriented mode, when the secured families purchase affordable housing, they own part of the property of the affordable housing, and become affordable housing property owners together with the municipal government. When the purchase time of affordable housing reached five years, the buyers can list their affordable housing for sale, and thus exit the housing security system, and it is clear that the exit mechanism is always accompany with the transfer of their property rights for affordable housing, therefore, to solve the property transfer problem of the affordable housing is conducive to the withdrawal mechanism for affordable housing and sustainable use of housing resources.

After a period of more than five years, the owners of China's existing affordable housing can hand in the land revenue and other related costs in accordance with the proportion of the Municipal

Government, thus obtaining full ownership of the affordable housing, they can trade their houses freely in the secondary market with market prices, and purchasers are not restrict to the access qualifications, resulting in affordable housing resources possessed by groups that outside the scope of housing security. Although the assignment of affordable housing property made families that no longer meets the eligibility for protection quit affordable housing successfully, but it did not increase the supply of affordable housing, instead it was accompanied by the loss of affordable housing resources.

To solve the above problems, the exit and title transfer of affordable housing can be implemented with separated operation of general commodity housing, on the one hand, the government can control trade prices of the affordable housing with the implementation of non-market price, which is determined by the welfare nature of affordable housing, on the other hand, the government should carry through strict entry eligibility assessment for affordable housing transaction, only those families which meet the access standards of affordable housing and are in the waiting state for placing have the right to purchase affordable housing. The exit mechanism, on the one hand makes the affordable housing resources circulate in the of objects of housing security, avoiding the waste of protection resources; On the other hand, reducing the funding pressure that the government repurchase the affordable housing, and thus reduces the implementation costs of the exit mechanism for affordable housing.

4 Conclusion

This paper presents the concept of inner circulation mechanism for security housing, through research on subsidies which changes from demand subsidy to mainly rent pattern, as well as different forms of title transfer issues and rental subsidies issues of security housing, we established the inner circulation mechanism for security housing, and strived to achieve recycling use of the housing security resources and sustainable development of security housing. Meanwhile, although the view proposed by this paper is certainly kind of scientific and targeted, but its practical guidance still needs to be strengthened, and further empirical research is still needed to support the application of this idea to policy recommendations and implementation plans.

Empirical Research on Innovation Path Selection of Express Service Company

Zhang Jianming

Huaxia College, Wuhan University of Technology, Wuhan, P.R.China, 430223

(E-mail: huozhetree@163.com)

Abstract: It firstly analyzes the necessity of service innovation of delivery enterprise and establishes the overall framework of basic path of innovation about courier service based on the theory of flower of service. Through two metrics of service needs and service costs, we propose three directions about selection of service path, namely basic items, innovative items and future items. Finally an empirical analysis about service innovation of a courier enterprise is presented. The study has important theoretical significance and practical guidance value.

Key words: Courier companies; Service innovation; Path; Theory of flower of service

1 Introduction

As an emerging industry, courier service has receiving more and more attention from people both in and outside the industry. Courier service is a consignment service which is fast in acceptance, transport and delivery of a single package, an addressed mail and other items without store, it can express mail to the recipient or the designated place in promised delivery time and get signed. It is characterized by fast, security, network, service and traceability. Courier service has a positive role in promoting the development of other industries and its correlation effect is significant^[1]. However, with the rising demand of courier services, courier companies have continued to remain at a lower level of service, and even show different degrees of decline. Courier companies must carry out service innovation if they want become bigger and stronger, and finally own the core competitive advantages. How to carry out service innovation, is an important and urgent mission faced by courier companies and even the whole industry.

2 Literature Review

The current academic have done some research on the issue of how to improve service levels of courier companies. Junhua Sun, Qiang Su (2009) established a fuzzy comprehensive evaluation method of courier service, they conducted evaluation and comparative analysis on Chinese express delivery service companies and proposed measures to enhance the level of service. Qing weiYan (2010) researched on quality improvement methods of courier companies from the perspective of the human resource management service. Shuping Wu (2010) proposed methods to improve the service in courier enterprises service based on the theory of service recovery. Tim Lau Don (2011) analyzed the appropriate service quality evaluation of the courier company and its influencing factors, proposed measures for improvement of the service quality. Meihong Zhu (2011) assessed and validated the dimensions, reliability and validity of the SERVQUAL model and provided some countermeasures and suggestions to enhance the level of delivery service with the modified model. Xudong Li (2012) established a courier service value chain model and proposed a long-term level enhance mechanism of courier service based on the optimization of value chain^[2].

Although the existing literature provides some research ideas, most of the literature just studied how to enhance the level of service delivery, and its focus limited to static optimization services, there is little literature focus on the issue of service level and scope of courier enterprises from the perspective of service innovation path. Drawing on the basis of relative research results, this paper proposed a complete set of service innovation path options for courier companies with the service flower model, and finally carried through an empirical analysis.

3 Necessity Analysis on Courier Service Innovation

In recent years, the rapid development of e-commerce drive the development of courier industry with unprecedented speed. The business volume of national wide courier companies totaled 1.86 billion in 2009, an increase of 22.8% year on year, operating income totaled 47.9 billion yuan, an increase of 17.3%; business volume of express delivery companies reached 2.34 billion in 2010, an increase of 25.8%. Business revenue fulfilled 57.46 billion yuan, an increase of 20%^[3]. China has become one of

the fastest growing countries in express industry in the world.

And still, a lot of problems emerged under the rapid development of delivery services, the most prominent one must be the decline in overall industry service level and gradually increase of service complaints. 315 Consumer Complaints Net of China handled a total of 17,536 valid complaints from courier industry in 2009, an increase of up to 70.9%; April 2011, through the "12305" consumer complaint telephone postal services and the national Post website, the State Post Bureau and the Postal Service of provinces (autonomous regions and municipalities) received a total of 5,234 consumer complaints in which involving issues with courier services 4744, accounting for 90.6% of the amount of complaints ^[4]. As can be seen from the above data, it is an important and urgent task for courier companies to take effective measures to improve the service level.

4 Basic Theories of Courier Service Innovation

4.1 Concepts and goals of Service innovation

In a narrow sense, service innovation means service-oriented organizations, aiming to gain greater business and social benefits, should provide their target customers more efficient, more thoughtful, more accurate and more satisfied service pack (which is a range of products and services consisting of the supporting equipments, auxiliary materials, significantly services, and other elements of stealth service). It includes several major forms such as the organizational structure innovation, service delivery methods innovation, service process innovation, and service operating systems innovation. Broadly speaking, service innovation means all types of organizations (or departments) continue to provide intangible services, tangible products or a combination of both, in order to create greater value and effectiveness and enhance customer satisfaction and loyalty .

From the above discussion it is obvious that the essence of service innovation is on the basis of a strong sense of innovation and integrated knowledge system, and careful analysis of the existing services in the goods, services marketing, service system and other conditions, strive to explore the development trend of commodities, services market as well as the potential demand service system modernization process, and constantly develop new services and the creation of goods, services, technology and service measures to improve the quality of service, and satisfy people in material, spiritual and other needs, and to achieve the efficiency unity of economic, social and environmental. Service innovation process is virtually the forming process of enterprises competitiveness by providing low-cost, personalized, high-quality services ^[5].

4.2 Service Flower theory

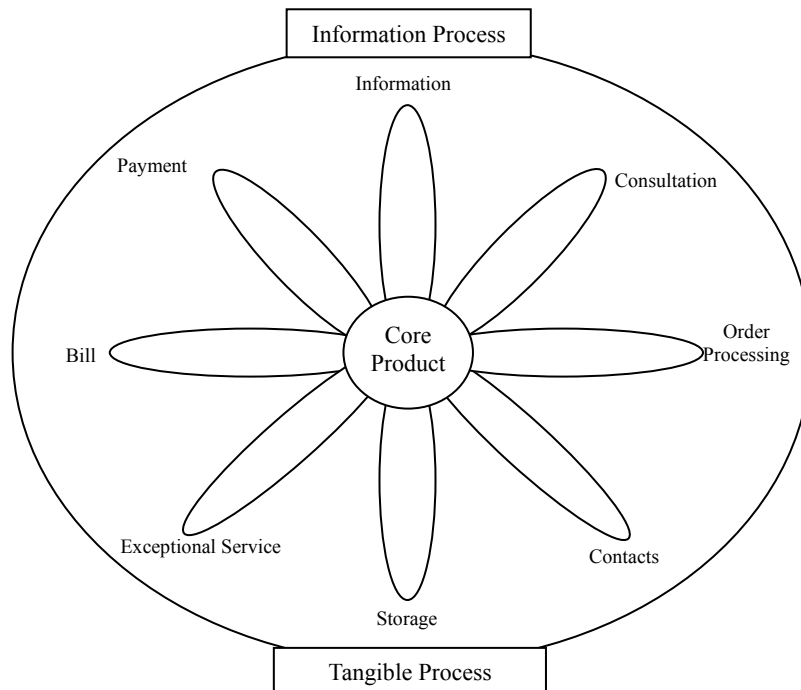

Figure 1 Model of Service Flower

There are many service innovation theories and methods. Chinese scholar Zuoyi Liu and Shaofu Du (2008) established a four dimensional model of service innovation refer to others' researches. In this model, the concept of service innovation, customer contact interface innovation, service delivery innovation are on their own stake, and the three elements are the main content of service innovation, and technological innovation is the key intermediate^[6]. The innovative approach of this paper mainly based on the service flower theory. Compared with the four dimensional service innovation model, the service flower model is more workable and with a wider coverage. Services business is initially presented by a famous American scholar in services marketing, Christopher • H • Lovelock, in his masterpiece "marketing service". From the standpoint of the overall product or service, it likens the relationship between the core product and the add-on product to the "pistil" and "petal" of a flower, focuses on how to add value to the "pistil" namely the core products through the "petals" namely the additional services. In which, eight additional products including information, consultation, order processing, contacts, storage, exceptional service, billing and payment, are like eight petals around the periphery of basic services, shown in Figure 1.

4.3 Analysis of courier services category

According to service flower theory, the courier service can be divided into core service and additional service. Core services are those services with most essential core value, the core services of the express industry is the service of fast delivery of goods to the customers. Additional services are derived new services which through the use of various technologies and different service delivery model and based on the value of core services, it is to expand the use of the product value. Additional services of express industry including eight areas: information services, consulting services, order processing, touch service, custodial services, exceptional service, billing services and payment services.

According to their role, additional courier services can be divided into convenient services and value-added services. Convenient service is an essential element of courier services, which includes information services, billing services, order processing, payment services. The so-called value-added courier service is a high additional value services developed by courier companies in order to meet the diverse needs of customers, which is based on its rapid web services and information technology support, its in-depth understanding of customers' service needs and the traditional "delivery" service^[7]. Courier services include consulting services, contact services, custody services, and exceptional services.

5 The Main Method of Innovative Courier Service

5.1 The building of the basic path in innovative courier service

Based on definition and basic content of eight elements of flower of service and the interviews of seven courier industry professionals, the researching group designs a questionnaire which also references to relevant literature. Survey includes courier employees, courier industry customers, courier industry researchers, and so. We send 120 questionnaires and 94 valid questionnaires are recovered, of which are 57 courier employees, 26 courier industry customers and 11 industry researchers. The ratios of innovative Path projects selected are above 60% and the projects which rate are lower than the 60% are not involved in the innovation path. Based on the statistics of questionnaire, we have compiled a summary of courier service innovation path.

Table 1 The Main Path of Courier Service Innovation

	Project	Definition	The main path
1	Information Services	In order to obtain the full value form any commodity or service, customers need relevant information.	Enterprise Service website; services Directory (including services items, service time, service prices, scope of services); service outlets directional; telephone or online free fast order and mail inquiry; SMS notification; safety warning signs.
2	Billing Services	Bills are almost all services' common elements. Safe and accurate billing is done to ensure a smooth transaction.	Site clearing, site confirmation bill; book-entry settlement (the bill, the amount payable); opened on behalf of policyholders; mobile POS settlement systems; collecting money, agent receipt.
3	Order Handling	Once the customer decides to purchase the products, the order processing begins. Order processing process should be polite, prompt and accurate.	Exchange and pay the orders on the network site; Telephone or online free fast orders; telephone booking orders.
4	Payment	Payment service which should be "Simple, safe, fast" provides customers with a more enjoyable shopping experience.	Shipper payment; Recipients payment; Third-party payment; Online payment; Automatically deduct; Pay for another; Cash on delivery for import.

5	Consulting	Consulting is a kind of quest to customers' needs, and then we design a targeted dialogue which can solve the program.	Advisory Service Manual; Through telephone, Internet exchange platform, live, radio, providing consulting services; Service tracking and feedback system.
6	Contacting	Touch service is a very beautiful petals, it reflects the pleasure of new customers and the greeting of old customers.	Etiquette and greetings; Free food, drinks and umbrella bags; Services and facilities of waiting area; The newspapers, magazines and television of waiting area; Pick-up and home delivery express.
7	Custody	Custody is taking care of the items which customers buy, purchase or rent. It is one of the important enterprise service capabilities.	Object holding; Free packaging; Regular mission services; Helping installation and commissioning; Conservation; The creation and maintenance of customers' file.
8	Exceptional Service	Exception service is an additional service beyond routine service delivery.	Overtime recipient, emergency submittal; Commodity inspection; Transportation of dangerous goods; Automatically sending and picking service; Abnormal parts service center; Exceptional service management manual.

5.2 The influencing factors of the innovative path selection.

The influencing factors of the innovative path selection include cost, demand, as well as the development of business and industry.

(1) Cost factors

The scope and depth of service innovation have the most directive contact to its cost of inputs. The service innovation requires investment, while service innovation is an important channel to raise revenue and reduce the cost. To some extent, the cost is an important indicator to measure service innovation.

(2) Demand factors

Customer demand is the most important factor to business services innovation. Customer demands for services can be self-aware, and it may be stimulated by external factors. The higher the customer demands for services, the greater the expectations of the service.

(3) Development factors

It includes the development of the industry and enterprises. Each company has its own corporate positioning and service localization. Only do Business find its own place in the fast-growing market and establish goals for each stage, they can continue moving forward on the road of innovation.

5.3 Classification of innovation path

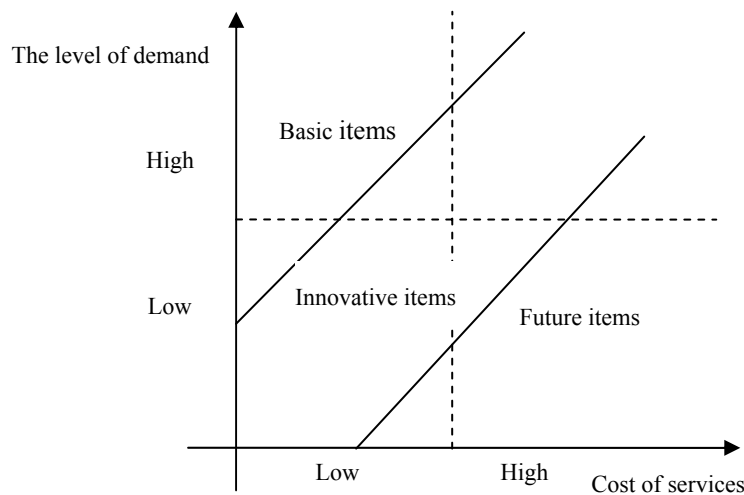

Figure 2 The Three Categories of the Primary Path

According to Table 1, the courier service innovation has 40 primary paths. Depending on service innovation factors of path selection, we build the category structure of service innovation path on the basis of the demand in the market and the cost of service, showing in Figure 2. According to the demand

and cost of services, we define the projects which have low costs and high demands as basic items. Basic items are the survival-oriented projects of express company and the most basic component of the projects. Innovation Project items is the interval between the low costs, demands and the high costs, demands. Innovation items are often overlooked by companies, but they can quickly achieve service improvements by investment and attention. The future items are the interval between the low demands and the high costs. At some stage, it may show higher service costs and lower demands. As time goes on, the above condition may change. Since it is difficult to achieve and the demand is not obvious, therefore, the future items are always becoming the long-term goal of enterprise service innovation.

6 Empirical Analyses

Company Y is a private courier companies, from past three years, the company has expanded rapidly, customer service problems gradually become the bottleneck for further development. Based on The main path in the service innovation, Research group produced a convenient service innovation path selection worksheets, and value-added service innovation path selection worksheets. Research team convened Y 12 all middle-level cadres, grassroots charge 21 people, as well as some level employees 27 people, two assignments table 40 projects sub basic items, innovative items and future items to choose, the proportion of each option maximum shall be final option. The results are shown in Table 2, Table 3.

From Table 2, Table 3 shows that, the Y company service innovation path, there are 19 Basic Items, 11 Innovative Items, 10 Future Items. Among them, the innovation Items for the company service innovation's the recent (During three year) work tasks, the future Items for the company service innovation's forward (three years later) work tasks. Companies were developed specific implementation plan on 11 Innovation items, while puts forward the basic idea of the work on 10 Future Items. Company's services work of innovative ideas become increasingly clear, objectives and task has become increasingly clear-cut.

7 Conclusion

Service innovation is the only way of the express company to achieve sustainable development in the fierce competition in the market. By courier service innovation path selection as the starting point, Clear the scope and main content of courier service innovation, promote various services step by step, improve service levels, establishing companies courier service system different from others, which is an important task of courier business foothold in the market, expanding the scale, sustainable development, form the core competitiveness of enterprises .

The Process of Global Brand Strategy Development and Regional Implementation

Davit Mkhitarian

School of Management, Wuhan University of Technology, Wuhan, P.R. China, 430070

(E-mail: mkhitarian_davit@yahoo.com)

Abstract: Although standardization-adaptation has long been recognized as a dynamic negotiation, less is known about the attendant processes within organizations. Accordingly, this study “pulls back the curtain” on a new global brand management strategy at Kimberly-Clark (KC). An extended case method was employed, comprising three rounds of semi-structured interviews with senior regional and global marketing managers on six continents. Global brand strategy development at KC entails sharing information and best practices, implementing common brand planning processes, assigning responsibilities for global branding, and creating and implementing effective brand-building strategies. Indeed, KC approach, predicated on accountable empowerment and capacity-building, is transforming the organization by increasing marketing capability locally while instilling better processes and disciplines centrally. An examination of these seemingly orthogonal objectives allows us to see how brand strategy cohesiveness is maintained in an unconventionally decentralized structure.

Key words: Global brand strategy; Standardization-adaptation; Extended case method

1 Introduction

The global integration of markets has spurred a convergence in consumer preferences (Townsend, 2009), prompting organizations to search for more effective ways to serve international customers and enhance their worldwide competitive positions (Wang, Wei, & Yu, 2008). Within this context, globalization is defined as the distribution and creation of products and services of a homogeneous type and quality worldwide (Moore, 2001). The attempts of multinational corporations (MNC) to globalize have resulted in the development and promotion of global brands (Townsend et al., 2009; Wang et al., 2008). Therefore, as competition globalizes, an MNC success hinges on its ability to position and manage brands across the numerous countries in which it operates (Lee, 2005).

Although most MNC recognize the advantages of global brands and the value of developing effective brand strategies that nurture their global identities, many are grappling with the challenges and complexities of competing in a global environment (Townsend, 2004). These complexities are amplified by the assumption that most MNC are regional, not global, and that there is no single global market or single global strategy (Moore, 2001). Thus, Townsend et al. (2009) argue that additional research using examples of the globalization of brands can provide managers and scholars with a deeper understanding of global brand management strategy. Prior literature has explored components of global branding and the ways MNC can exploit global opportunities, but limited attention has been paid to branding within a global context (Arnold, 2008). Furthermore, no consensus has been reached on the relationship between global standardization and centralization in global branding (Quester & Conduit, 1996).

We sought to extend current knowledge of global brand management by deconstructing and learning from the strategies and processes of a well-known and successful global MNC. The study viewed the global brand-building process as a dynamic capability of MNC, and the research therefore considered how dynamic and ongoing tensions are managed between global standardization and local adaptation, as well as the resultant decisions that shape corporate strategies and processes. Our focal MNC was Kimberly-Clark (KC), which provided an ideal and constant context by “setting the limits on the range of relationships to be expected”, (Johns, 2001, p. 33). KC global marketing and branding strategy has recently undergone extensive changes, thereby providing a rich context within which to understand the processes, procedures, and practices involved in becoming a Global Marketing Organization. After presenting an extended case method (Kate, 2006), we focus on understanding the dynamics of the KC setting in order to explore and build theory (Yin, 1994).

2 Literature Review

2.1 Conceptualizing global brand

Aaker and Joachimsthaler (1999) provide a more detailed definition, proposing that global brands are “brands with a high degree of similarity across countries with respect to brand identity, position,

advertising strategy, personality, product, packaging, and look and feel” (Aaker & Joachimsthaler, 2000, p. 306). Global brands can therefore be envisaged as tools that enable organizations to portray and manage consistent corporate and brand images across a diverse customer base.

According to AC Nielsen (2001), a brand can be considered ‘truly global’ if it is sold in all 30 countries used in the sample (which represent 90% of the world's gross domestic product), and if more than 5% of its sales come from outside of its home region. Further, Inter-brand (2006) identifies six principles shared by the Best Global Brands: recognition, consistency, emotion, uniqueness, management and adaptability. Kleenex, one of KC core brands, was named a billion dollar brand that could be considered truly global based on these definitions and principles (AC Nielsen, 2001; Business Week/ Inter-brand, 2009).

2.2 Global brand management

Although extant literature is replete with examples of ‘global’ brands (Jain, 1989), there is a dearth of prescriptive theory on “how brands become global” (Townsend et al., 2009, p. 540). Several global brand management strategies have been proposed, but they tend to be limited to specific business contexts (Ger, 1999; Walker, 2003). In a more generalizable sense, Van Gelder (2003) calls for brands to be ‘harmonized’ across markets to ascertain which aspects of the brand proposition should be the same across markets. These core aspects can then be standardized without upsetting (but rather, inspiring) local managers and/or consumers. To determine the best way to manage a brand globally, firms must understand the extent to which factors relating to the brand vary across national boundaries (Van Gelder, 2003). Moreover, managers should be aware that in some instances, a single brand cannot be imposed on all markets (Keegan & Green, 2005). To achieve a balance between standardization and local adaptation, Kapferer (2005) proposes seven globalization strategies, all based on the notion that the brand is a system consisting of concept, name, and products or services. Thus, MNC must also deduce what processes and strategies can be standardized and how best to manage decision making authority within their organizations in order to find the balance necessary to manage global brands.

2.3 Centralization and decentralization

Centralization determines the extent to which decisions are made at high levels of executive authority in an organization, while decentralization delegates decision making to lower levels of authority (Zannetos, 1965). The type of decision making method that will be used is usually determined at an organizational (Edwards, Ahmad, & Moss, 2002) or marketing level (Özsomer & Prussia, 2000). Edwards et al. (2002) further explore these decision making philosophies in terms of the level of autonomy an MNC gives to its subsidiaries. However, determining how much control an organization exerts over its subsidiaries is not easy (Harris, 1992). Indeed, most global organizations embrace both philosophies (Heiden, 2007). Success in global markets may therefore require MNC to incorporate both centralization and de-centralization in their structures to enable them to act quickly locally while leveraging global best practices.

3 Research Approach

3.1 Study context

KC is one of the world's leading manufacturers of health and hygiene products, with manufacturing facilities in 36 countries and products marketed in more than 150 countries. In addition to being a large MNC in terms of geographic scope, KC is ranked 126 on the Fortune 500 list (Fortune, 2010). Moreover, AC Nielsen (2001) identified Huggies and Kleenex, two of KC flagship brands, as billion dollar brands that ‘could be considered truly global’. Recently, however, KC adopted a global brand management strategy aimed at increasing inter-organizational alignment and standardization. KC therefore provides a unique example of how global brands are managed in an MNC that has recently shifted from decentralized, regional brand management strategies to a global brand management strategy.

3.2 Research design

The study employed the extended case method (ECM) (Kate, 2006) to examine global brand management. Kayla and Eckhardt (2008) note that ECM is the preferred method for researching the types of global and cultural questions explored in this study because it “engages with the contexts in which the phenomena occur” (p. 218). Moreover, single case studies are considered more effective in providing theoretical insights than are multiple cases (Dyer & Wilkins, 1991). Thus, single case studies can be used to describe real-life contexts in which interventions have occurred and explore situations in which the intervention being evaluated has no clear outcomes (Yin, 1994).

3.3 Interview protocol and sample

A semi-structured interview approach was used. Interviews ranged in duration from 45min to 75 min. Telephone interviews were used in phase one, followed by face-to-face interviews in phase two and a combination of telephone and face-to-face interviews in phase three. With the interviewee's permission, all of the interviews were recorded to facilitate coding and the interpretation of direct quotes, as well as to increase the accuracy of the findings (Eisenhardt, 1989). Due to the semi-structured nature of the interviews, the research protocol acted as a mechanism for guiding conversation. In total, we interviewed fifteen respondents (see Table 1 for respondent profiles). Of these, nine had global roles and six had regional roles. Of the regional respondents, one was from Asia, one from Australia, one from Europe, one from sub-Saharan Africa and two from South America.

3.4 Data analysis

The first stage in ECM (Kate, 2006) involves the reduction of empirical data into a set of themed materials. The second stage involves explaining the studied phenomenon in the context of existing theory to better understand the larger context shaping the phenomenon. Descriptive codes based on the literature review were created before the interview phase commenced. The goal of coding is to 'fracture' findings (Strauss, 1987) into categories that permit comparison and thereby facilitate the development of theoretical concepts. Once the interviews were completed, the descriptive codes were considered in terms of the data to explore emerging patterns within that data. The pattern codes permitted the themes identified by the descriptive codes to be elaborated further, enabling more thorough analysis. Initial codes were based on the research questions, which allowed the interview to be conducted analytically and ensured that the coding was linked to the conceptualization of the research.

4 Results

4.1 Decision making autonomy

To understand the issues and obstacles facing KC over autonomy and control between global and regional teams, we explored the perceived roles of global and regional marketing team members. Interviewee 3 observed, "The U.S. business is very different from the state of play in India, Turkey or South Africa...so there's...a necessity for...local positioning, but within the umbrella of...some governance around what we want the...brand to stand for". KC global strategies seek greater alignment of their brand offering, but interviewee 5 admits that "there's probably some standardized processes that our global and regional communicators use, but we're still trying to get more aligned and merged". However, any uniform strategy would, according to Interviewee 7, "...fall apart because of the consumer nuances, the language in which you speak about the product. The need states that can be satisfied by the same product can be a wide spectrum of needs". Since standardization can be perceived as an impediment to innovation and creativity, KC global brand management strategies attempt to reduce mandatory elements, thus allowing the regions to adopt and adapt within a prescribed framework.

Interviewee 4 explained, "...at the end of the day, every market has to do what's best for them. However, part of the reason why these jobs like mine exist within this company is to provide...freedom within the framework. So we have to establish some frameworks 'because you don't want...your brands to mean different things in different places". The KC framework uses various processes and templates to determine what a brand stands for, and allows the markets to "adapt what's relevant for them" (Interviewee 4), thereby giving the regions "almost total autonomy" (Interviewee 3) and creating "powerful regional organizations" (Interviewee 10) that have the ability to "pick and choose" (Interviewee 2) the strategies most relevant to their market. This strategy aligns with Thrassou and Vrontis (2006) assertion that marketing strategies should be customized to suit the unique dimensions of each market. Although senior executives lead KC global brands in roles created by the recent marketing/branding restructuring process, the findings suggest that, given the firm's organizational structure, the global marketing/branding team lacks the blanket ability to mandate strategies. "My role", Interviewee 4 clarified, "is to establish what the strategy is and then establish...how each market executes their strategy because every market is in a different place in terms of development of competitive set and so forth. So then we have an overarching strategy in terms of this is what we want...and what we want the brand to mean. These are our business objectives. These are the innovation platforms that we're going to work on, and then we translate that down into each market and how each market is going to execute that".

Table 1 Respondent Characteristics

Interviewee	Position	Role	Region
<i>Phase 1</i>			
Interviewee 1	Regional Marketing Director	Category/Region Specific	Southeast Asia - regional
Interviewee 2	Senior Brand Manager	Brand/ Country Specific	Southeast Asia - local
Interviewee 3	Global Brand Director	Brand Specific	Global
Interviewee 4	Global Marketing Director	Category Specific	Global
Interviewee 5	Global Communication Director	All Categories and Brands	Global
<i>Phase 2</i>			
Interviewee 6	Global Digital Director	All Categories and Brands	Global
Interviewee 7	Global Brand Director	Category Specific	Global
Interviewee 8	VP of Corporate Innovation	All Categories and Brands	Global
Interviewee 9	Global Marketing Operations	All Categories and Brands	Global
Interviewee 10	Chief Marketing Officer	All Marketing Functions	Global
<i>Phase 3</i>			
Interviewee 11	VP Global Brands	All Categories/Brands	Global
Interviewee 12	Regional Director	One Major Category	Regional (Europe)
Interviewee 13	Regional Marketing Leader	One Major Category	Andean Region (Latin America)
Interviewee 14	Regional Marketing Leader	One Major Category	Andean Region (Latin America)
Interviewee 15	Regional Marketing Leader	One Major Category	Regional (sub-Saharan Africa & Middle East)

Overall, the interviewees agreed that the global roles focused on applying and transferring global best practices, even though they had no “line of authority over regions or countries” (Interviewee 3). This experience is consistent with Aaker and Joachimsthaler's (1999) findings that global brand managers and teams often have little authority to mandate the strategies they create. Indeed, Interviewee 3 observed that the global role seemed to be about “influence, suggestion, coercion...[and] negotiation”. Interviewees implied that communicating the value of new strategies and persuading regions to “opt in” is the best way to overcome autonomy issues.

4.2 Balancing global standardization with regional adaptation

KC is attempting to “get as many synergies and efficiencies as it can without subjecting itself to a one-size-fits-all view of the world” (Interviewee 11). This method of change management aims to embed the fundamentals of global branding in the regional teams, thereby increasing their adoption of best practices. Starting with its core brands, KC global team completed segmentation studies on six key markets whose regional leaders volunteered for the process. This segmentation work “established global strategic targets, consumer targets, and target audiences, and illustrated key target segment characteristics in various geographic locations” (Interviewee 11). Thus, with a consensus process similar to the one already used inter-regionally, the global brand team “prioritized needs” and created a global brand promise and associated architecture. With the same strategic plan in mind, regional leaders then adapted these promises and architectures to create a more regional focus based on local market opportunities. This process combined “bottom-up local market insights and requirements and ideas with...top-down strategic assessment of the brands' problems and opportunities” (Interviewee 12).

The purpose of establishing global branding fundamentals was thus to “change people's perspectives” so that they became more brand driven and used the “right analytics before making decisions”. Therefore, if data were used as a guide for regional decision making, the findings from global studies and the results from global best practices would be enough to increase strategy adoption. However, research budgets are limited, and the “sit on the side line and cherry pick” attitude remains prevalent, particularly in the countries that were not part of the global studies. A global mindset is required to overcome this attitude, a mindset that increases the degree to which people opt in and requires an exception to opt out. This is consistent with Heiden's (2007) argument that MNC should empower subsidiaries by giving them greater autonomy while using centralized strategies to enhance consistency and corporate compliance. Thus, without any distinct plans to reduce the autonomy of the regions, KC is seeking greater alignment and adoption with “mechanisms to drive compliance”, such as standard brand measures that allow for regional comparison and medications to employee objectives and remuneration.

4.3 Building regional marketing capability

Interviewee 12 saw the underlying tenant of the current global brand strategy as being less about the standardization issue itself and more about building regional marketing capability and elevating the marketing function within the organization globally. In fact, Interviewee 12 commented that KC CMO challenged and inspired regional marketers “to do great work”. This view matches the practice of

facilitative leadership, where managers promote critical thinking and act as mentors or coaches to improve employee capabilities. According to Simonin and Özsomer (2009), however, facilitative leadership is typically insufficient in disseminating knowledge among subsidiaries. Nevertheless, other manifestations of a firm's commitment towards developing a knowledge-sharing culture, such as instituting formal mechanisms and processes for knowledge dissemination, can encourage knowledge transfer and sharing. Consistent with this notion, Palmer introduced rigorous new marketing processes and disciplines and created a culture of sharing whereby regions submit their best work for peer review. If a regional office has a genuine need to deviate from global strategy and a genuine capability to execute great marketing, the Global Sector Leadership team will empower it to act more independently. Otherwise, the regional office will be strongly encouraged to share and borrow from global best practices.

5 Conclusions

Our findings explicate how KC has implemented numerous changes to become a global marketing organization. According to Interviewee 10, KC global brand management did not appear to be about control and influence: "...control in this environment, in this world, is completely overvalued. It is all about influence and inspiration and getting people to do it because they want to...You've got to inspire them and lead them to do it..."With this sentiment rooted in its management philosophy, KC is seeking to strike the right balance between "multiple market development and local inspiration" (Interviewee 8). Interviewee 15 added that, as in all matrix structures, regional marketing leaders must be good influencers. They do, after all, perform staff functions, not line functions. Finally, Van Gelder (2003) contends that firms should standardize global brands by inspiring, not upsetting, local managers, an argument reiterated by Palmer.

The success of KC global brand management strategy depends on balancing consistency with regional decision making autonomy. It is, notes Interviewee 8, about "delivering new benefits...in multiple markets with similar positioning, similar communication, similar product formats" without losing its local footprint or global dominance. Interviewee 7 explained that balance can be achieved by "satisfying real, un-met consumer needs on a local level...Meeting those local-level needs and then aggregating them up and looking for commonalities that might then become a global mindset and a global platform". Such balance, Interviewee 7 believes, will occur through a non-systemic, evolutionary change, assisted by global brand teams that act as "great facilitators". The balancing point between global standardization and local adaptation is dynamic; organizations are "living organisms that transfer knowledge and grow in capability"(Interviewee 10), and organizations such as KC should be designed to meet changing consumer needs. Is KC new global brand strategy working? Preliminary evidence suggests that recent marketing strategy changes have indeed resulted in superior financial performance. For instance, after KC improved the dissemination of regional insights within the firm, its North American division adopted successful brand strategies from Israel and Australia, a move that increased United States market share in the associated product lines vis-à-vis KC chief competitor, Proctor and Gamble. More generally, a recent independent financial analysis predicted that KC would experience sustained financial growth in the coming years, due in part to the improved sales growth of its brands. The early evidence confirms that recent changes in the firm's global brand management process have enhanced its performance.

(E-mail: 375378355@qq.com, sjxwhsh@163.com, 282677686@qq.com)

Abstract: This article establishes ISCO four-dimensional design management innovation system model based on analyzing and summarizing the latest design management theories, especially Four-Three structure model which proposed by professor HU Shuhua in Wu Han University of Technology, with the experiences and lessons of famous companies, such as Apple, Samsung, and Nokia and so on. The model builds a new innovative design management system by integrates inputs, subjects, contents and outputs four aspects which are considered for industry and regional innovation. The purpose of the model is to make a analysis and appraisal reference model for design management innovation.

Key words: Design management; Innovation; ISCO; System model

1 Introduction

Design management is not only manage the design project, but also a purposeful and organized activity that can affect strategic decision of a company even can affect the develop strategic decision of a country. In the fierce competitive marketing, the design activities are becoming more and more complex. The method like Human factors engineering, Universal design, User research, Interaction design, User experience are always promoting design to develop and improve, so that Design management become more and more complex. Wei Wang from China Bridge said that the main difference between China and west countries in industrial design is that the companies of west countries have a high-quality design management system.

Now in china, design management is in its infancy, but the international competitive environment forced us to catch up with and surpass the trend of the world to improve our design and design management. Design-driven innovation theory is one of the forefront of research design management proposed by Roberto Verganti in 2003^[1]. Chen Xue Song is the earliest scholars who systematic study of design-driven innovation in china. The traditional model of innovative power is the market pull and technology push model. And design-driven innovation is driven by the product language (meaning) to be technological innovation and market innovation. Roberto Verganti believes that firms should constantly communication with artists, designers, educational researchers and other external "interpreter to achieve and spread new language product^[2]. Charles C. Snow and others established a model of collaboration between enterprises from industrial background, organizational design and other aspects of output and profit^[3]. And Chen Jin and Chen Xue Song establish mechanisms model by designing elements of design-driven innovation, design innovation ability and design innovation result^[4].

But we think Design management is a systematic project, which needs to consider the whole process of the activity of design business. So we want to establish ISCO four-dimensional design management innovation system model which constants input, subject, content and output four diminutions. "ISCO" are the four capitalized first letter of words of input, subject, content and output which must be carefully considered for industry and regional innovation.

2 Models and Method Analysis

2.1 Main theory

The ISCO four-dimensional structure model proposed by Professor HU Shuhua (previously named "four three structure" model), this model is developed from input-output theory and black box theory. The "I" is input, the "S" is subject, the "C" is content, the "O" is output; it is mainly used in regional innovation development research field, analysis and diagnosis regional innovation situation through input elements, innovation subjects, innovation information, and output target. This theory model accommodate the input-output feedback principle, subjects and contents hierarchical mechanism, contents and outputs hierarchical correspondence principle ,outputs and subjects directivity transform principle.^[5]

Generally speaking, design management system can be summarized as resources, methods and

results .Company use resources, technology and management to transform design elements to be new product or service. (See Figure 1)

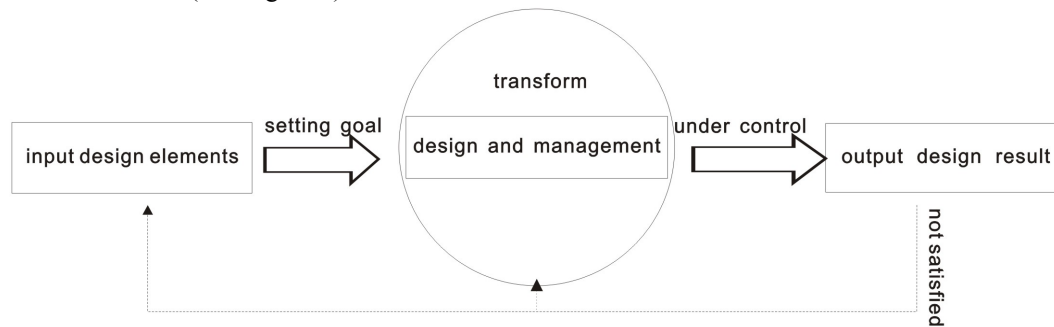

Figure 1 General Design Management System

Consolidated the changes in the field of consumption, marketing, technology A kind of “big design” concept in the design of management is gradually formed. Its manifestations are divided into: large collaboration, namely parallel design with the rise of collaborative design; large integration, means that design must by way of communicate with user experience and use a variety of media. Having creativity without losing continuity and systematization^[6]. So we need to build a structure model to help enterprises analysis overall design management innovation. And four-dimensional structure model should be a good choice.

2.2 Model operational mechanism analysis

(1) Input to output mechanism. The results of output related to input elements and conversion process. If you want to have good output, you must have good resources and cooperate with excellent management.

(2) Elements of synergy mechanism .According to the principle of bucket short board, no matter how strong the other factors are, the ultimate effect of product is decided by its weakest. So the design management innovation success is not put into some factors, but need to integrate the internal and external resources, multi-pronged can increase the likelihood of design management innovation.

(3) Loop feedback mechanism. From input to output is not a single route, the process of integration and conversion of resources will have feedback information. Output can reflect if inputs are reasonable. Check the conversion process through consideration of the results of monitoring, can timely to guide resource inputs and improve the management innovation method. Good results will promote further innovation.

(4) Subject and object conversion mechanism. Subject is the executor of behavior. Object is the object that subject wants to influence or change. But they can transform to be the opposite side. From the perspective of enterprise, designers and design managers are human resource, and design management is objects. But from the perspective of design and management, designers and design managers are the subjects of innovation.

3 ISCO Four-Dimensional Factors

3.1 Design of innovation inputs

3.1.1 Talents

Talents are indispensable fundamental resources of design innovation and innovation management. For design management innovation inputs, talents are designers and design managers. When Steve jobs back to Apple, the company is losing money, in order to realize the innovation of management and design ideals, Jobs tried to find out the most excellent designers and design managers. Finally,one design director in the company whose name is Jonathan Ive is the best one. Thanks to Jonathan Ive, who made jobs realized many genius idea to perfect and implementation Designers and design managers is the core of the design or design driven enterprises, enterprises from top to bottom should be respected for design to fully understand and support.

3.1.2 Funds

According to the statistics of American Association of Industrial Design, when enterprise spent \$1 in design and development, they will get \$2500 averagely; Japanese Hitachi one statistics show that for every 100 billion yen in sales increase, the role of industrial design (51%), and technical reformation effect accounted only for 12% more and more companies are beginning to take industrial design as the

enterprise profit leverage and brand building tools.

3.1.3 Working environment

Environmental design innovation management as inputs of reason is that a good design environment, Can promote exchanges and cooperation between design team members and inspiration. Many companies can create a communication and discussion of office space, such as audi, hearing aid company in Denmark found that the natural interaction between the different floor staff in stairwells, widen the stairs. Sweden's Ericsson's London headquarters in abstract beautiful staircase to link together the floors.....The purpose of adapting their workplace is enhanced the natural basis of everyone meet each other and communication.^[7] Similarly Apple's design teams with engineers, marketing personnel even peripheral manufacturers have close contact. IDEO also often work together to organize specialists in different areas, The most direct way to deal with problems is to make the building designer, architect graphic designer client meeting together, found problems in different areas, then carries on the overall planning.

3.1.4 Platform

Contains the immateriality platform: Such as knowledge information platform of network media, as well as the materiality platform like warehouse design model making platform. Platform's function is to promote the sharing of knowledge and experience, enhance the design efficiency.

3.2 Design management innovation subjects

3.2.1 Enterprise senior manager

Corporate executives are the major makers of design activity, design strategy and design policy. If understand design will decide the fate of design department, even the whole company. MOTOROLA is the first inventor of cell phones which once the leader of mobile phone industry. But the senior executives just concern engineering and technology, and took less attention to design content and users, made their phones less and less popular. At the same time companies such as apple, Samsung fully awareness the important of design, and took design content and ser experience as product design center, fully fusion art and technology in design, make their phones very popular. Master policy trends and concerns of the market trend is the corporate executives' one of the most important thing.

3.2.2 Design manager

Design manager is the executor of the design strategy and the concrete design project, the head of the positive contact design agencies and institutions. A good design manager should achieve the overall strategy of the enterprise. Enterprise should give more freedom to their design managers to try.

3.2.3 Designer

Designers are both design resource, and subject of innovation management. They are the core of design activities who are the executor of the design strategy and design activities. Apple's Jonathan ive used new tool materials and technology with constantly experiments, designed many breakthrough new products. Such as iMac, iBook, the PowerBook G4 and iPod MP3 player. Designer should think positively and needs to find out.

3.3 Design management innovation contents

3.3.1 Design strategy

Design strategy is a long-term planning to create the future. As the development of design with economic globalization, more and more companies accept the Design-driven strategy. Creating design brand is already the focus of large companies. IDEO CEO Tim Brown proposed that design thinking is people-centered innovative approach which requires integration of the needs of users, technological feasibility and commercial success. I think nobody will doubt that Apple's success is that Steve Jobs made the company focus on the concept of industrial design, and pushed design on the same status with technology.

3.3.2 Design identity

Identity system generally includes concept, behavior, and visual identity. Corporate should set up their own image system include design concept, design behavior and visual identity once adjust the design strategy. Every large group will conduct a comprehensive brand identity design for each new brand, even modify the company's identity system. For example, Apple removed "computer" out off its name in January 2007, then positively develop phone business.

3.3.3 Design content

Italian scholar Roberto Vergant put forward the concept of design -driven innovation after a study of some Italian corporates design strategy in 2003. And he thinks that the basic of design innovation is that each product has its own language and meaning. The appearance of the product is juest the one side

of all. Now is the era of experience economy, design contents should be focus on user experience, otherwise no matter how high technology a product have, it will lead to a invalid design or unpopular. Motorola and Nokia were once brilliant in China even the world more than ten years, have advanced management technology and manufacturing technology, and always focus on it, do not carry on the design content updates ,that lead to the demise of the entire enterprise.

3.4 Design management innovation output

3.4.1 Product

The product here contains general industrial products, apparel, services and other design results. Designing new products or services is the basic requirements for design innovative, and also the key ability to further success. New products should not only be innovative in content and form, but should give more attention in whether it is user-centered or meets the needs of users’ experience.

3.4.2 Performance

Performance includes individual performance and organizational performance, that is, we should not only consider the output of innovation in new products or services, but should give more attention in considering whether the organization's objectives are achieved, whether the individual's innovation and management capability are improved.

3.4.3 Brand

In the earlier stages of development, the most important thing of companies is to survive, they might focus on just design as more as possible, don't have the energy to consider how to build a brand. But companies have to create their own brand if they want to go further. For large enterprises, they should make a new product to be a new brand, just like the iphones, obviously not just ordinary products.

3.4.4 Standard

“First-class design for standard, second-class design for brand, third-class design to make products”, it means that the bottom line of design management innovation is new product, while the highest is firstly captured the market opportunities and have the right to make industry standard.

According to above, design management innovation system would be summarized as innovation subjects input design resources to create innovation results through design contents. Different design content needs different resources and will get different outputs. Design management innovation model extracts different design contents in common, While generalizations same factors for summarizing and explaining the general design management. (See Figure 2) .

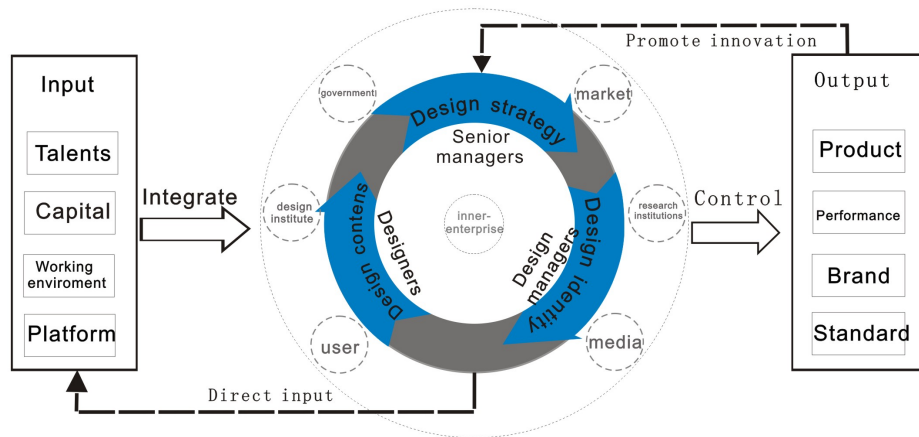

Figure 2 ISCO Four-Dimensional Structure Model of Design Management Innovation System

4 Conclusion

Design management is a systematic project, which needs to consider the whole process of the activity of business. Design management innovation is also not just one factor changing, but involves a series factors. Now, Nokia is trying to regain the world's top mobile phone market status, so far the mobile phone design updated, and administrators also changed, but shortage design innovation inputs, design innovation and design contents. Although they have innovative products, the innovation performance is still far lower than Apple and Samsung, even not to say innovation brand and standard. ISCO four-dimensional model integrated inputs, subjects, contents and outputs four aspects, may be used as the analysis and appraisal reference model of design management innovation.

Research on the Synergetic Performance Evaluation of High-Tech Enterprises

Chen Ruiqing, Wang Liyan, Yang Qing

School of Management, Wuhan University of Technology, Wuhan, P. R. China, 430070

(E-mail: chenruiqing@catarc.ac.cn, wlyan@whut.edu.cn, yangq@whut.edu.cn)

Abstract: The synergetic performance of high-tech enterprises is the foundation to promote economic growth and society development. This paper presents the principle of synergetic matrix and synergy degree, and establishes the model of synergetic performance evaluation. The results show that the enterprise is comprised of several subsystems, each composed by multiple factors. The synergetic performance of each subsystem is decided by the synergy degree of elements and performance of the system together; the synergetic performance of enterprises depends on the synergy degree between subsystems and the synergetic effects of enterprises' performance.

Key words: Performance evaluation; Enterprises' synergetic performance; Systems' synergetic performance; Synergetic matrix; Synergy degree

1 Introduction

The development of the high-tech enterprise is an inexhaustible force for economy and society growing, and will eventually become the ideal method to stimulate the economy. Synergetic performance of high-tech enterprises is the foundation to promote economic growth and development. How to evaluate the synergetic performance of high-tech enterprises has become the focus of research and development of high-tech enterprises.

In the field of synergetic research, Haken^[1], a German physicist, put forward synergetics. Bradley et al.^[2] got synergistic gains based on abnormal returns. Healy et al.^[3] evaluated synergistic gains with performance improvement. Later, advances in calculation methods of abnormal returns, changes of the calculation benchmark and others were provided by other more researchers. Andrei et al.^[4] established a model for evaluating financial synergies from mergers and acquisitions. Yu Shunkun^[5] carried on an empirical analysis during the power grid enterprise staff through the use of F-ANP synergetic evaluation method.

From the review of existing research results, it is obvious that, the achievement of synergetic performance research is not enough, and research to the high-tech enterprise synergetic performance is much less. This paper presents the principle of synergetic matrix and synergy degree, and establishes the model of synergetic performance evaluation.

2 The Performance Evaluation System of High-Tech Enterprise

2.1 Design of performance evaluation system of high-tech enterprises

High-tech enterprise performance evaluation subsystem mainly includes the leadership and command system, human resource system, technological system, supply and marketing system, and financial systems. The frame of high-tech enterprise performance evaluation system has been shown in figure 1.

2.1.1 Leadership and command system

Leadership and command system of high-tech enterprise is mainly about the enterprise senior managerial staffs' personnel coordination and communication skills. Performance evaluation of the system can be composed of some elements, such as coordination and communication skills of general manager, sales manager, production manager, financial department manager and technical manager.

2.1.2 Human resources system

Human resource system, a subsystem of the enterprise system, is the source of core competitiveness and sustainable competitive advantage. There are a lot of performance evaluation index system of human resources, such as training and development, compensation and benefits, employee relations and motivation, internal coordination and other indicators, depending on the enterprise own situation.

2.1.3 Technology system

Technology system is the whole about business and technology associated with a series of activities. It is an important component of the high-tech enterprises' technology system. So far there is a great

number of literatures about this system whose evaluation index including technical team, the ability of R&D, support conditions, output and effectiveness.

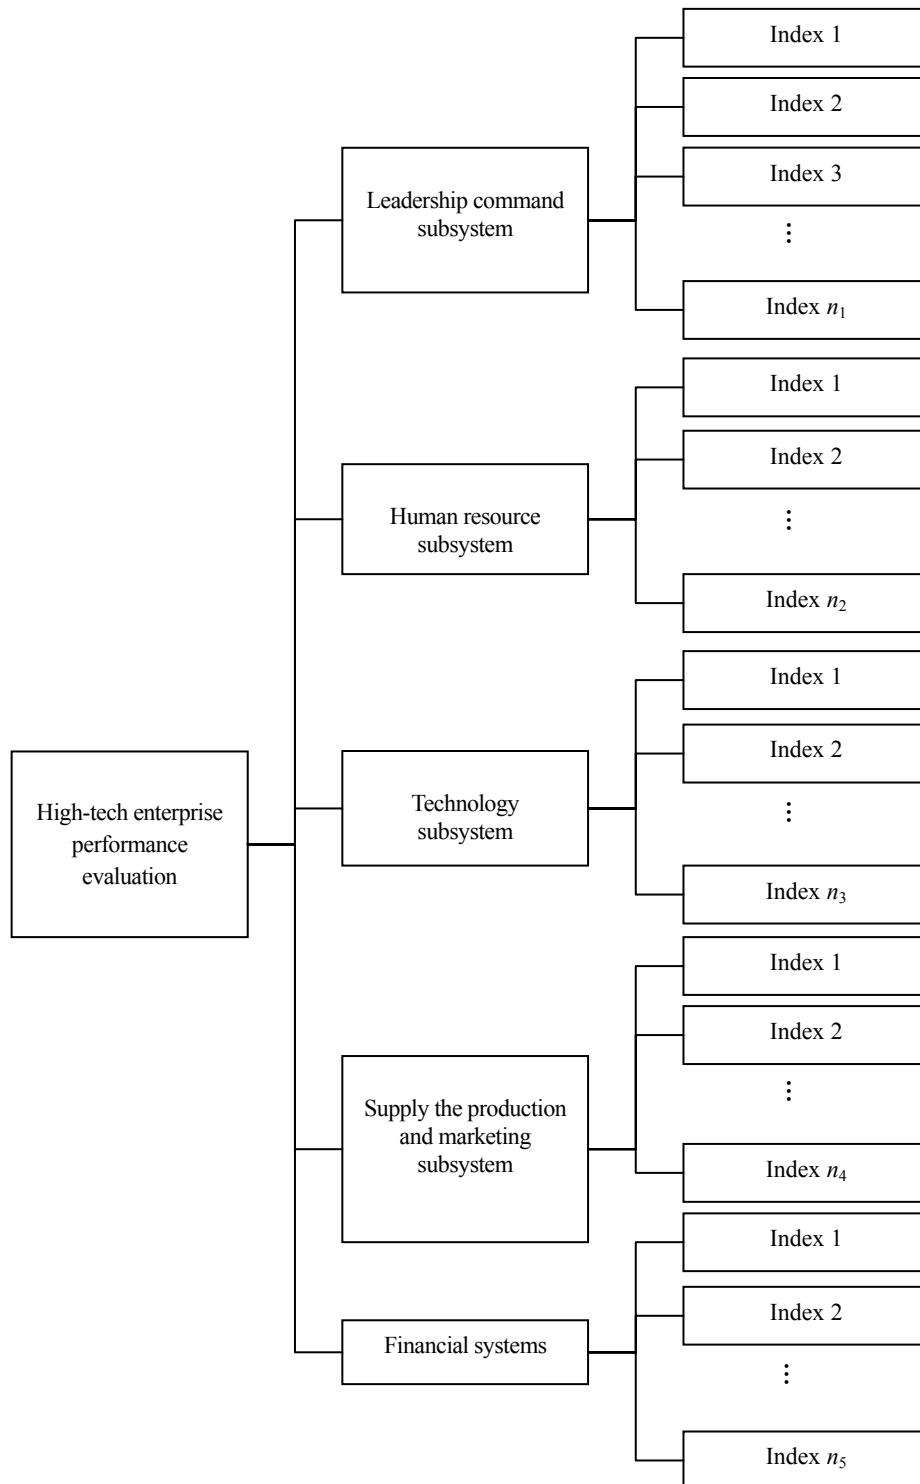

Figure 1 The Framework of High-Tech Enterprise Performance Evaluation System

2.1.4 Supply, production and marketing (SPM) system

Supply, production and marketing system, also known as the supply chain system is responsible for the enterprise’s production and distribution. The system’s performance can be evaluated by purchasing

process, the competitiveness of products, customer service and information sharing and other aspects.

2.1.5 Financial system

The financial system, based on the financial goal, is responsible for establishing organizational structure, position, management responsibilities and labor configuration, to reflect, supervise, control, and coordinate business and financial activities. The performance appraisal system mainly investigates the enterprise in terms of profitability, asset quality, debt risk status, and business growth.

2.2 The principle and method of high-tech enterprises' performance evaluation

2.2.1 Principle of performance evaluation

From theory analysis, performance evaluation of high-tech enterprises belongs to comprehensive evaluation. Through two mappings, the comprehensive evaluation^[6] will map disordered points in space to the orderly points in space, so as to achieve the purpose of optimization.

If using m indexes, then this m indexes constitute a space A . The space A is m -dimensional, each dimension has a specific unit (dimension), and the unit is not necessarily the same. Any one of the average object m index of the actual value constitutes point a in the A .

The first mapping of comprehensive evaluation is to use them m function f , turn the index of each evaluation object of the actual value x_i into scores of all index values of y_i , i.e.:

$$y_i = f(x_i) \quad (1)$$

Seeing from the space the space A is mapped to the space B , i.e. $f: A \rightarrow B$. The space B is m -dimensional, each dimension is no unit of measurement (which is expressed as a fraction). By mapping f , a point a in the space A is mapped to a point b in the space B .

Second mapping of comprehensive evaluation is the use of weighted average method (the important weights of each index is w_i), turn the index of each appraisal object evaluation value y_i into an integrated index z , i.e.:

$$z = g(w_i, y_i) \quad (2)$$

On the analysis of space is that the space B is mapped to the space C , i.e. $g: B \rightarrow C$. The space C is one-dimensional.

In two mapping of comprehensive evaluation, the space A is m -dimensional, and the dimensions of the units are not necessarily the same. It is in disorder, whose points are not in space size comparison. The second space B is m -dimensional, and is in disorder, but each dimension is no unit of measurement. The third space C is one-dimensional, and is orderly, any ordered space points can compare its size.

2.2.2 The process of the performance evaluation

Although there are many different kinds of evaluation objects, features, goals' vary, comprehensive evaluation procedure is the same in general.

(1) Determine the evaluation target of evaluation object. Define the overall goal of the evaluation object and target clearly, make its connotation and denotation border clearly, and definite objectives between the primary and secondary and subordinate relations.

(2) Establish comprehensive evaluation index system. Indicator is the embodiment of the connotation of the target and the determination of the measurement scale.

(3) Determine the index values (or indicators data standardization processing). Determining the index values have two aspects, one is defined index quantification; the second is to index standard.

(4) Determine the index weight. Due to the importance of each indicator towards target is different, namely each indicator's contribution is different, and therefore, different indicators should be given different weights.

(5) Construct the comprehensive evaluation model. Comprehensive evaluation result is not the simple sum of the index values. The comprehensive evaluation results need to be processed based on the certain mathematical method, which is called evaluation model.

(6) Sort the comprehensive evaluation result. Each object of the evaluation is sorted according to the comprehensive evaluation result, and then makes a choice and decision.

In each link of the comprehensive evaluation, the index system is the premise, index standardization of data processing is the foundation, the index weight is the key, and the comprehensive evaluation model is the core. In order to get reasonable conclusion for each link, we must carefully study system analysis. Each link must be studied carefully and analyzed systematically in order to get reasonable conclusion.

2.2.3 Model of performance evaluation

Comprehensive evaluation of a lot of mathematical model, but the essence can be divided into the weighted arithmetic average and weighted geometric mean of the two main basic models. That is:

$$z_a = w_1 \cdot y_1 + w_2 \cdot y_2 + \dots + w_m \cdot y_m$$

$$= \sum_{i=1}^m w_i \cdot y_i \tag{3}$$

$$z_b = y_1^{w_1} \cdot y_2^{w_2} \cdot \dots \cdot y_m^{w_m} = \prod_{i=1}^m y_i^{w_i} \tag{4}$$

In the formula z_a as the weighted arithmetic mean evaluation object values; z_b as the weighted geometric average value of evaluation objects; w_i for the i evaluation index weights, there are m indicators, $\sum_{i=1}^m w_i = 1$; evaluation object y_i is value for the score function index i , it is the index value of the standardized data processing after the score, $y_i = f(x_i)$, the i index to evaluate the value of the object x_i .

Weighted arithmetic average model synthesize indexes in the form of addition, and the weighted geometric mean model integrate these indexes with the multiplication. Therefore, weighted arithmetic average method is simpler; the weighted geometric mean method is more sensitive for the score differences between indicators: once an indicator valued as zero, its comprehensive evaluation must be zero. Using this feature and according to the following evaluation principle, we can choose comprehensive evaluation model.

(1)“Good match” evaluation principle, that is allowed to use some high score to make up for some low score of indicators, reflects policymakers’ efforts to optimize for the guiding ideology, if using the principle of weighted arithmetic average model is optional.

(2) “Cannot be ignored” evaluation principle, which is not allowed to use some high score to make up for some low score of indicators that reflect decision makers’ comprehensive and balanced optimization of the guiding ideology, if using the principle of weighted geometric average model is optional.

(3)The “ambiguous” evaluation principle, it is a mixture of the above two kinds of evaluation principles, namely:

$$z_c = (z_a + z_b)/2 \tag{5}$$

3 The Synergetic Performance Evaluation Model of High-Tech Enterprises

3.1 The synergetic performance evaluation model of subsystem

3.1.1 The synergy degree matrix of element

For each subsystem, which includes the leadership and command system, human resource system, technology system, SPM system and financial system, each system is composed of multiple elements. For each element, they have the synergistic relationship.

In the leadership and command system for example, the subsystem of S_1 , assuming that consists of five main elements: general manager, vice president of technology, CFO, vice president of sales, vice president of production, construction of the synergy degree matrix is as follows:

$$B_1 = \begin{bmatrix} - & a_{12} & a_{13} & a_{14} & a_{15} \\ - & - & a_{23} & a_{24} & a_{25} \\ - & - & - & a_{34} & a_{35} \\ - & - & - & - & a_{45} \\ - & - & - & - & - \end{bmatrix}$$

Among them, a_{ij} means the synergy degree of factor i and factor j .

3.1.2 The synergy degree model of element

In the leadership and command system, according to the synergy degree matrix of elements to establish average the synergy degree model, i.e.:

$$b_1 = \sqrt[10]{a_{12} a_{13} a_{14} a_{15} a_{23} a_{24} a_{25} a_{34} a_{35} a_{45}}$$

The principle is extended for application. If the subsystem of S_i has n elements, the elements of synergy degree are:

$$b_i = \sqrt[n(n-1)/2]{a_{12} a_{13} \dots a_{1n} \dots a_{(n-1)n}} \tag{6}$$

3.1.3 The synergetic performance evaluation model of subsystem

In the leadership and command system, the comprehensive evaluation model can be set up system S_1 , and its performance as Z_1 while the synergetic performance as U_1 is:

$$U_1 = \sqrt{b_1 \bullet Z_1}$$

Similarly, for any subsystem of S_i , the synergetic performance is:

$$U_i = \sqrt{b_i \bullet Z_i} \tag{7}$$

3.2 The synergetic performance evaluation model of enterprise

3.2.1 The synergy degree matrix of subsystem

Assuming that m subsystems as $S_i (i=1, 2, \dots, m)$, between subsystems the synergetic degree matrix is:

$$D = \begin{bmatrix} - & c_{12} & c_{13} & \dots & c_{1(m-1)} & c_{1m} \\ - & - & c_{23} & \dots & c_{2(m-1)} & c_{2m} \\ - & - & - & \dots & & \\ & & & & \dots & \\ - & - & - & - & - & c_{(m-1)m} \\ - & - & - & - & - & - \end{bmatrix}$$

3.2.2 The synergetic degree models between subsystems

The synergetic degree model between subsystems and the synergetic degree model of elements are the same principle, the synergetic degree between subsystems is:

$$d = \sqrt[m(m-1)/2]{c_{12} c_{13} \dots c_{1m} \dots c_{(m-1)m}} \tag{8}$$

Among them, m means the number of subsystems.

3.2.3 The correction performance evaluation model of enterprise

The correction value (V) of high-tech enterprise performance for each subsystem (S_i) of the importance weights (w_i) and synergetic performance (u_i) of the weighted evaluation, i.e.:

$$V = \sum_{i=1}^m w_i u_i \tag{9}$$

3.2.4 The synergetic performance evaluation model of enterprises

According to the synergetic degree of system and correction value of enterprise performance, the synergetic performance evaluation model of high-tech enterprises (CV) is established as:

$$CV = \sqrt{d \bullet V} \tag{10}$$

4 Conclusions

The enterprise is composed of several subsystems. Each subsystem is composed by multiple factors. The synergetic performance of each subsystem is decided by the synergetic degree of its elements and the performance; the synergetic performance of enterprises depends on the synergetic degree between the subsystem and the performance of synergetic results.

The Proposal of Metrics and Evaluation Methods to Explicit Knowledge of the Absorptive Capacity

Kenji Miyake¹, Yoshiyuki Matsuura², Ken Kaminishi²

¹ Graduate School of Science and Engineering, Yamaguchi University, Yamaguchi, Japan 755-8611

² Graduate School of Innovation and Technology Management, Yamaguchi University, Yamaguchi Japan, 755-8611

(E-mail: s011wc@yamaguchi-u.ac.jp, matu@yamaguchi-u.ac.jp, kaminisi@yamaguchi-u.ac.jp)

Abstract: The importance of Absorptive Capacity has been stated in many previous researches. When small and medium-sized enterprises with poor management resources perform product development with an outside-in open innovation approach, one of the important factors determining the success or failure is Absorptive Capacity of the licensing-in company that form a foundation of technology learning. In this paper, we propose a method for evaluating the Absorptive Capacity of the company, and it is intended to propose a method for utilizing Absorptive Capacity as a measurement of “readiness” to external knowledge.

Key words: Absorptive Capacity; External knowledge; Open Innovation

1 Introduction

Since the open innovation is advocated by Chesbrough (2003), the promotion of innovation by utilizing external knowledge, including industry-university cooperation is in the spotlight more and more in Japan. Outside-in open innovation, that is to say licensing of technology itself is widely being used among large corporations in Japan, for the Japanese company where it is supposed that it has an independent management tendency about technical development (Not invented here; NIH syndrome), an accepted technology has a high possibility that only a restrictive and complementary role will be given. Therefore, the way of organization appropriate in open innovation era is explored. (Motohashi et al., 2012).

One of the major important factors that determine the success or failure of the outside-in open innovation is Absorptive Capacity (AC) of the licensee company that form a foundation of technology learning (Veugelors and Cassiman, 1999). Since AC was applied to microanalysis by Cohen and Levinthal(1989,1990), although many researchers have studied AC theoretically and empirically, it is claimed that the original meaning of AC is becoming ambiguous through these studies (Lane et al., 2006; Volberda et al., 2010) and a redefinition is tried (Zahra and George, 2002; Todorova and Dursin, 2007). However, an investment for activities of all studies that focus on AC is common in that the value to the organization of external knowledge is influenced (Fabrizio, 2009), and as the definition of Cohen and Levinthal (1990) has been widely accepted most (Murovec and Prodan, 2009), in this paper, we define AC as “the ability of an organization to recognize the value of new, external information, assimilate it, and apply it to commercial ends”.

Many previous studies have been to clarify the factors that improve AC of an organization. As a typical factor, they can cite in-house R&D investment (Cohen and Levinthal, 1989), skills that employees possess (Vining, 2006), past joint R&D experiences (Becker and Diaz, 2004), routine of the organization (Zahra and George, 2002) and organizational culture (Van Den Borch et al., 1999) etc. .

As given condition which is with an effect of AC to give innovation and a factor to influence AC accumulation, to apply to decision making to introduce a concept of AC into actual external knowledge, it is necessary to be operationalized to derive an answer to questions such as the following: “Given the current status of our own company, what is the activity to contribute to improvement of AC most?” or “As for the premise of our current AC, is it possible to implement innovation that utilize an external knowledge?”. We thus believe a framework that provides guidance to those questions would increase the possibility to exploit the concept of AC as management techniques. However, AC is essentially qualitative and so far as we know, it cannot be said that the trial of quantification is performed enough until now. In this paper, we have devised a framework for assessing this question, and it is intended to propose a method for utilizing AC as a measurement of "readiness" of its company to external knowledge.

We think that AC quantification is especially suggestive when SMEs with poor management resources aim at innovation which utilized external knowledge. AC is cumulative, and it is said that it is also important to have the broadness of knowledge (Cohen and Levinthal, 1990). As for this, from a

viewpoint of accumulation of AC, it is thought that the possibility that SMEs have advantages for large enterprises with use of external knowledge is extremely low, if other conditions are set the same. In other words, SMEs which are implicitly inferior to AC are considered to mean that working as a creator is effective as an accepting person of knowledge. The uneven distribution of AC depending on the corporate scale can support progress of the inside-out open innovation by SMEs theoretically, but the outside-in opening innovation by SMEs does not suggest the situation becoming effective in it alone.

In order for SMEs which face a resource constraint to compete for big-firms, a network with outside plays a decisive role (Dodgson and Rothwell, 1994), in addition, it is apparent that the level of AC is an element which is more important to innovation by SMEs so that it is insisted when an actor connecting the company and the outside environment is assets which are important to SMEs (Noteboom, 1998). Furthermore, as represented in the cluster policy, it is strongly desirable from the point where the outside-in innovation by SMEs, the growth of the company by it will lead to the development of local economy (Maskell and Malmberg, 1999). In Japan, in spite of many political activities, the penetration into SMEs of industry-university collaboration, which is a representational approach of the outside-in innovation, does not reach sufficiently level.

Madrid-Guijarro et al. (2009) states that the human and financial barriers have a negative correlation with innovation in SMEs, additionally and they tend to hesitate to funding from outside due to the high risk of innovation. Innovations that utilizes external knowledge, and if the risk is higher (the cognitive theory at least) than when based on the knowledge that was created internally, it is expected that SMEs become more cautious in practical use of external knowledge. If we assume this, in order to promote efforts of outside-in open innovation by SMEs, we consider that it becomes important to show objectively whether innovation that utilized external knowledge accompanies allowable risk assuming the company's AC.

In this paper, we describe the evaluation indices and methods for AC which is basically tacit in nature.

This paper is made up from 6 chapters. In the 1st section, we mentioned object of the paper, purpose and the background. In the 2nd section, we will perform an analysis of previous researches of AC with a focus on small and medium-sized manufacturing companies in Japan. In the 3rd section, we will explain a framework of this research. In the 4th section, we will do the evaluation and analysis of two AC case studies by a patent map which is the framework of this research. One is Ball Semiconductor case that does not result in commercialization of a maskless lithography system, the other is PMT case that is successful for the commercialization. In the 5th section, we will explain the implications of in when you aim at innovation which has a core of external technology, and conclusion in the 6th section.

2 The Previous Work about Absorptive Capacity

For AC, since there are many good quality review papers, I describe some of the previous research about the importance of AC which pay attention to small and medium-sized manufacturing companies in Japan.

According to the analysis of a company survey, in terms of manufacturing industry, Kodama (2010) states that the development of product type SMEs which has design and sales competences of in-house manufactured goods that has much research and development result such as patent application or new product development and they has power of utilizing industry-university cooperation, cooperation with a big firm, and cooperation with SMEs in research and development result. The ability to effectively apply external technology or scientific knowledge with other universities and other firms is called AC, and just by having the ability for external knowledge and technology to be utilizable, it is supposed that they can have needs which tackle industry-university cooperation and cooperation between companies positively. Motohashi (2005) also supposes that existence of AC which performs additional technical development which takes in fundamental knowledge of a university in the innovation process in the company for a success of industry-university cooperation that is important in the R&D-oriented company. Hosoya (2013) examined a survey of manufacturing niche top companies in Japan and found a background that they have been maintained to a high level of AC compared to other SMEs through continuation of business and product development.

As a way to enhance AC, since the research and development that was assisted publicly produce a learning effect, the company will enhance the ability to obtain the latest scientific and technical knowledge (Okada and Kushi, 2004).

In industry-university cooperation from above previous researches, we have found importance of

AC and the enhancing method of AC in the organization. The preceding studies conceptually show importance of the high AC for the result of cooperative project such as industry-university collaboration. This has inhibited to be analyzed based on a framework for the AC to SMEs poor management resources to increase the success probability of industry-university collaboration. In this paper, we aim at the proposal of a tool for solving this problem. The following section develops our AC evaluation framework.

3 Absorptive Capacity Evaluation Framework

Many of the previous researches have set up R&D expenditure as a proxy variables of AC. However, with most of SMEs, the acquisition of AC is performed implicitly to large extent (Vinding, 2006), in addition, R&D activity is performed in private in many cases (Muscio, 2007). As well as Muscio(2007), we focus on human resources, that is, we evaluate the AC based on the experience level of the members of the organization more directly. Although the AC of organization is not a simple sum of the organization member's AC (Cohen and Levinthal, 1990), considering that the organizational learning be realized only through personal learning (Nicolini and Menzar, 2007), besides, the knowledge in SMEs strongly depend on the person characteristics, we think that there is a certain reasonableness in this approach.

Decision-making on the introduction of external knowledge (technology) is performed subject to a fixed knowledge set unit at the time. In other words, it is natural to think that the product concept is formulated at least when considering the introduction or business utilizing any such knowledge. And by thinking in combination technical resource of its company with technology under consideration, it will be judged whether innovation which utilized external knowledge is realizable. Therefore, in order to construct metrics of AC, a higher level abstract concept, as a measure "readiness," we should associate with the specific product concept.

Although it is assumed that it is fully recognized in the company about inside information, and it can be accessed in the previous work of AC (Tu et al., 2006), since the maldistribution of knowledge has taken place as mentioned above in SMEs, there is also a case which is hard to be referred to as that the internal knowledge base is recognized enough by the decision maker. Therefore, subjective judgment of the president who is a decision maker in many cases has always conceived a possibility of becoming a thing based on recognition of an inaccurate knowledge base. In addition, if the judgment is not based on a reasonable understanding of the knowledge base of its company, it leads to challenge which does not suit the company's capacity, and the risk of jeopardizing the survival of the company is higher. Thus, assuming a company's knowledge base, by the setting of the benchmark to judge whether the introduction of a concerned knowledge set is permissible, we think that we can promote outside-in open innovation of SMEs by supporting the decision making to introduce appropriate outside knowledge into SMEs.

All the industrial products consist of several different engineering components. For example, the main technical component of a liquid crystal panel is constituted by the combination of many technical components like method of display mode (For example, multi domain vertical alignment (MVA)), active element (for example, thin film transistor (TFT)), light volume controller (for example, polarizing plates) and display driver (for example, traffic light controller). In this paper, we propose a method that evaluate AC by decomposing a concerned knowledge set into technical components. By decomposing in this way, even SMEs without the knowledge base for evaluating knowledge systematically, they can consider their AC for external knowledge set under consideration and will be able to evaluate more objectively. However, decomposition into the technical components of the product is difficult if not experts in the product and service. So, this paper shows how to use a citation and quotation patent map by Patent Gazette, as a method of decomposing unfamiliar knowledge set into the technical components mechanically. Many previous researches have described the necessity for the patent map in patent analysis. For example, it is said that in order to remind the intellectual property strategy of their company by recognizing a technical trend as a fingerprint like an illustration, and what is called a technical fingerprint, and grasping it from patent information (Kiryama, 2009). However, this paper is the first trial to utilize a patent map as an evaluation tool of AC, as far as we know.

First, as a method of decomposing into the technical components mechanically for a licensing-in patent, Patent Gazette which patent examiners quoted in the examination process "for patent assessment", are considered to be the technical components which constitutes the patent. Then, as a way to mechanically identify main technical components from the quote Patent Gazette of those (technical

components), a technological contents of the Patent Gazette are cited with a large number of other Patent Gazette that is considered to be important components of the technical license. Therefore, it is possible to find out main technical components for the technical license mechanically by performing the sorting in descending order of number of citations for the quote Patent Gazette (technical components).

Next, we evaluate by “Excellent> Good> Average> Bad” for own AC of main technical components which were extracted. The basic idea is in the definition of Cohen and Levinthal (1990) about each technical component, it means that AC belonging to an individual about concerned technical elements is enhanced whenever we go a step, such as "recognize", "assimilate" and "apply".

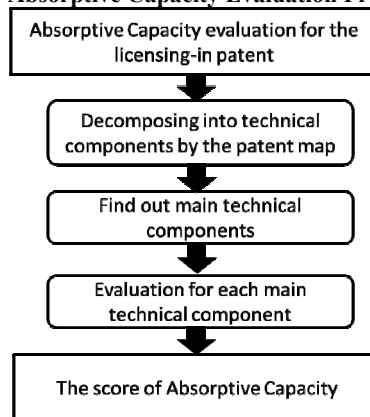

In addition, it is where there is debate about whether more than the number of citations is made into as main technical components, but we should assess all reviews if the number of the quoted Patent Gazette (technical components) is less than 10. However, since those technical components will become in redundant if it becomes 100 or more, about the top 10 % is considered to be appropriate.

Although the previous research has presented many factors as variables for the each construct as "recognize", "assimilate", and "apply" (Jean-Pierre Noblet et al., 2011), when we consider the effectiveness as a decision-making tool in SME, the simplicity of measurement is also important . Based on the above, each evaluation criteria is defined as follows.

- If SMEs have a track record of product development using the technical component, it should be evaluated as “Excellent”.
- If SMEs have the special engineer who takes charge of the technical component, or made a related research paper and related patent application, it should be evaluated as “Good”.
- If SMEs have engineers to understand the technical component, it should be evaluated as “Average”.
- If SMEs do not have the technical component engineer, it should be evaluated as ” Bad”.

Finally, as an evaluation index, each evaluation of “Excellent”, “Good”, “Average” or “Bad” will be given points of 100, 75, 50 and 25 respectively, then obtain an average score. In case of the higher score, it is estimated that AC of its company to perform the licensing-in patent is higher, and it is expected that the industrialization achievement probability of commercialization will be higher. Thus, it is possible to quantitatively evaluate the AC of its company using the patent map for quotation & citation by the Patent Gazette in this way. The AC evaluation procedure for each technical component with the mentioned above patent map is shown in Table 1.

Table 1 Absorptive Capacity Evaluation Procedure

First of all, without ability to search of the promising external technology, we cannot perform innovation that utilized external technology. Although the framework of this paper is utilizable also for evaluation of AC in the viewpoint of recognition of a certain external knowledge group, the evaluation of cognitive power to each external technical set requires a multi-faceted discussion, such as a method for a knowledge group definition. In this paper, since we have focused on AC as a measure of readiness for specific external knowledge set, we would like to suppose to hand over the evaluation framework of recognition relates to "recognize" to another paper, and we will define the external knowledge set under consideration in this paper, we will show how to apply the framework in the next section.

4 Case: Mask-Less Drawing Equipment

The use of the AC evaluation method described above is illustrated by comparing the two

companies for which it was going to realize the same product innovation by taking in external technology from the same university researcher by practical use of industry-university cooperation.

Mr. Ishikawa who was former vice president of Texas Instruments, Inc. (TI) founded the Ball Semiconductor, Inc. (Ballsemi) at Allen in Texas, U.S., in October, 1996, with \$US 52 million of capitals, 50 employees, and develop and manufacture spherical semiconductor sensors, medical device and photovoltaic device.

PMT Corporation (PMT) is the SMEs in Japan, \$US 500,000 of capitals, and about 100 employees, it starts from a trading company, and becomes a research-and-development type company through outside-in open innovation by industry-university cooperation, and major business is the manufacture of a semiconductor manufacturing related equipment, ultra-precision axis control related equipment etc..

4.1 Case Outline

It is necessary for various process technologies in semiconductor manufacturing, the semiconductor technology has been making drastic progress by lithography process to do microfabrication in particular. The exposure equipment transfers an integrated circuit on a wafer in the lithographic process. The exposure equipment performs the transfer in reduction projection onto a wafer by using a mask drawing a circuit pattern obtained by dividing each layer integrated circuits. The number of masks required for one kind of semiconductor manufacture needs 20 to 40, and mask cost for a submicron or a nanometer patterning semiconductor is about \$US 10 million to \$US 100 million, even at the micron level, the mask cost is some \$US 10,000. Furthermore, it is needed long lead-time that is 1 to 3 months. High running costs are required to maintain the mask in this way.

In order to solve this issue, CEO/CTO Ishikawa of Ballsemi had an idea that used TI DMD (Digital Micro-mirror Device) chip instead of the mask, because he had a profound knowledge of DMD when he was vice president of TI. He conducted industry-university cooperation with a professor of Tohoku University to develop a mask-less drawing technology with DMD, and he performed the patent application with Tohoku University. This does not need a mask and transfers a circuit pattern to a DMD chip and draws a circuit pattern on a wafer with a reduction projection lens by scanning X-Y stage in sync with the transfer speed (Figure 1). However, this equipment development did not lead to up to commercialization.

Figure 1 The Mask-Less Drawing Technology with DMD

On the other hand, PMT has acquired an ultra-precise XYZ stage control technology with a resolution of the nano-level performance through the "development of micro-nano fabrication system" by METI (Ministry of Economy, Trade and Industry) regional consortium. In addition, a researcher who has a PhD in this field was also joined.

The professor had continued research and development even after the end of joint research with Ballsemi, and PMT has been able to achieve commercialization of the mask-less drawing equipment with Tohoku University by taking advantage of public subsidy (supporting industry program) that is "Research and development of pattern generation technology and positioning accuracy of the microfabrication device". In this way, originally Ballsemi started innovation of the mask-less drawing equipment with a researcher of Tohoku University and let PMT succeed it in licensing-in later and has achieved commercialization. The interest of this paper is to explain why Ballsemi was forced to abandon the commercialization of joint research results, while PMT was able to come out. We will analyze and evaluate the difference in AC of both companies with the citation and quotation patent map by Patent Gazette which is the framework of this report.

Figure 2 is a quote-cited relationship diagram of Japanese Patent Laid-Open No. 2005-1567788 of mask-less lithography system that Tohoku University has been filed. Table 2 shows the number of quotes-citations in Japanese Patent Laid-Open No. 2005-1567788. As can be seen on the patent map, the

patent examiner referred to 246 Patent Gazette in order to determine "refusal" or "patent assessment". As for that we can say, the mask-less drawing equipment is constituted by very much inventive technical components. In other words, it is expected that the commercialization is very difficult if AC of these technical components is lacking.

4.2 Implementation of the AC Evaluation Framework

Since Patent Gazette with much number of citations is generally a fundamental patent for the invention, we suppose that the mask-less lithography system is possible to utilize technologies described in these publications. The roughly top 10% that is referenced more than 15 times are supposed having important technical components that are indispensable for the mask-less drawing equipment, and as shown in Table 3, we suppose technical component of the mask-less drawing equipment by analogy from the technical component of each Patent Gazette. For each technical component, based on the interview with Ballsemi and PMT, we evaluate as “Excellent>Good>Average>Bad” with the criteria mentioned above. Finally, for each and adding points 100,75,50,25, to obtain an average score. As a result, the metrics of the AC for Bollsemi is 46.9 points, while PMT is 73.4 points was found.

PMT has achieved the commercialization of the mask-less drawing equipment due to highly AC of each technical component, on the other hand, since Ballsemi was insufficient for AC of the ultra-precision moving control technology for the stage which synchronized with the pattern data transfer speed which is the most important technical component of the mask-less drawing equipment, we suppose that it did not technically lead to the product development. In addition, Ballsemi licensed out the technology to a company in Japan, which successfully commercialized.

Table 3 The AC Rating for Each Technical Component of the Mask-Less Lithography System

No.	Published patent#	Title	Applicant	# of quotation	# of received citation	Technical component for the patent	Technical component for the patent(2005-156788)	Absorptive Capacity

								Bad: 25, Average: 50			
								Good: 75, Excellent: 100 point			

5 Implications

When aiming at an innovation which used external technology as the core, with AC of its company by evaluating on the quotation & citation patent map which is a framework of this research, it is possible to build an associate base of the management judgment such as licensing-out, licensing-in, outsourcing-in, partnership networking, etc..

Even if we carry out technical search and learning of the collaborative investigation and then created some kind of knowledge, the subsequent activity is not connected directly to the conclusion whether you should carry out in-house. When AC is insufficient like Ballsemi, a management judgment which carries out licensing-out to the other company can be attractive. Ballsemi acquired the loyalty by it, and the company which did licensing-in has succeeded in commercializing.

On the other hand, you can perform a management judgment to enforce licensing-in when you have enough AC to its commercialization as PMT. In addition, if there is a technical component which is

insufficient of AC, you should not give up R&D or commercialization, you should consider a management judgment which complement the lack of AC with open innovations, such as outsourcing-in and partnership networking, can also be made. Since PMT did not have an optical technology, the development of the technology was assigned to the external optical special marker. However, since an integration, such as adjustment, was required in order to incorporate an optical system in the equipment, currently PMT has employed optic engineers in the company.

6 Conclusion

When the product development type SMEs, where R & D resource is scarce, performs a licensing-in of a seed which a university or a research institution have, and commercialize with a unfamiliar technical component by industry-university cooperation, AC which assimilates and takes the technical component into its company is required. As a method to evaluate this, we extracted major technical component by the quotation & citation patent map by Patent Gazette and showed the method to evaluate the company's AC for it through the case study of the mask-less drawing equipment of Ballsemi and PMT.

If the evaluation score is low, the commercialization can be made by performing the licensing-out to other companies as example of Ballsemi. In addition, when an evaluation score of a technical component is low, neither development nor commercialization can be given up but a management judgment compensated with the lacking technology by licensing-in etc. can also be made.

However, when making the decision to embrace external knowledge, it does not necessarily mean that we should only take an external knowledge group that scores high. A high score suggests the height of the technical vicinity of external knowledge to company knowledge base, and suggests the height of the feasibility of commercialization. On the other hand, the decision to accept only high score promotes conservative posture against external knowledge as it implies to accept what is familiar and is at risk of inhibiting learning about external new knowledge. Therefore, in order to aim at the expansion of AC (Zahra and George, 2002) as a dynamic capability that affect the sustainability of the company's competitive advantage, you need to have a variety to the score of the external knowledge acquisition project which exceeds the lower threshold of AC designated in the company. A strategic judgment is necessary whether we should try it, even if AC score is low if it is risky yet promising project.

Finally we should show the limit of the approach developed in this report. Needless to say, this paper is exploratory research, and must be validated by the application to many cases. Be premised on it, when the seeds which a university or a public research organization create have limited path dependency from existing technical component, since there are few numbers of Patent Gazette which a patent examiner quotes, it is difficult to extract main technical components through the quotation & citation patent map. In addition, the evaluation method of this report is not applicable when technological components of the seeds are unobservable. In addition, even if we have the given conditions which is the validity of attention to individual, we must consider the need to consider the influence on AC such as individual learning ability, motivation, and personality. We would like to make these points in a future discussion.

The Impact of Customer Participation on Innovation Capability: Moderating Role of Power Asymmetry*

He Yong, Zhang Jing

School of Management, Huazhong University of Science and Technology, Wuhan, P.R.China, 430074
(E-mail: wddhyws@163.com, jingzhang@mail.hust.edu.cn)

Abstract: This study outlines a model of why and how the respective influence of customer participation on innovation capability is likely to be moderated by the level of power asymmetry. The results are based on a sample of 256 firms in the B2B market of china. By testing our model using hierarchical regression, the results generally support the proposed hypotheses, in that power asymmetry has a significant negative moderating effect on the impact of information sharing and responsible behavior on innovation capability. In contrast, we find that power asymmetry has a significant positive moderating effect on the impact of personal interaction on innovation capability. Implications for management theory and practice are discussed.

Key words: Business-to-business market; Customer participation; Innovation capability; Power asymmetry

1 Introduction

In the focus of recent literature on capability research, an attempt to explain capability differences between firms has shifted from firms' internal elements to industry-level external relationships. Co-create value with customers can be necessary in a fiercely competitive environment. The topic of customer participation and its deterrent has been dealt with extensively in recent years. When focusing on innovation capability there is a great deal of room for further investigating how customer participation impacts a firm's innovation capability. Customer participation means the degree to which the customer is involved in producing and delivering the service (Dabholkar, 1990), which we focus on in the business-to-business (B2B) market of china. This study examines the innovation capability of B2B firms in order to better understand relationships between customer participation and innovation capability.

Power asymmetry refers to the degree to which one firm holds substantially more or substantially less power than another in a cooperative relationship (Pfeffer, 1981; Cani, 2009). Strategic management scholars have dedicated considerable effort to understand the power asymmetry effect (Johnsen & Ford, 2008). Although a few pioneering studies have examined how power asymmetry may affect the relationship between co-creators and firm-level performance, little is known about how power asymmetry influences customer participation and thereby differentiates firm's innovation capability. Because of continuing competition between co-creators, an investigation of the role of power asymmetry offers substantial value and importance to practitioners. Moreover, an investigation of the role of power asymmetry may refine our conceptual understanding of the customer participation-innovation capability link.

Given this, the authors argue that a close customer-firm relationship is important in the acquisition of information, in responsible behaviors and in personal interaction, if customers participate in value co-creation process. Specifically, we propose that power asymmetry play a moderating role in the linkage between customer participation and innovation capability. In order to further understand the effects of differing customer roles in value co-creation process, we adopt Ennew and Binks' (1999) categories, customer participation including following three dimensions: information sharing (CPIS), responsible behavior (CPRB), and personal interaction (CPPI). We examine the effect of customer participation on B2B firm's innovation capability and subsequently by assessing the moderating influence of power asymmetry on the relationship between customer participation and innovation capability.

Drawing from arguments of customer participation, innovation capability, and power asymmetry, through this richer explanation and empirical assessment, we contribute to greater clarity of how customer participation may contribute to successfully developing innovation capability. In the next section, we develop the theoretical model and hypotheses, drawing on prior literature from several

* This paper is supported by the National Natural Science Foundation of China (NSFC 71272125).

theoretical disciplines that have studied customer participation. The details of data collection and analysis are then presented, and the results are discussed. The paper concludes with implications and suggestions for further research.

2 Literature Review

2.1 Customer participation

Customer participation is defined as “the degree to which the customer is involved in producing and delivering the service” (Dabholkar, 1990). Meuter and Bitner (1998) distinguished among three types of service production based on the level of customer participation: firm production, joint production, and customer production. The argument suggested by Vargo and Lusch (2004a), that the “customer is always a co-creator,” serves as one of the foundational premises for the emerging dominant logic of marketing. Further, Prahalad and Ramaswamy (2000) advocated co-opting customer competence as a competitive strategy. Customers are no longer “passive audience,” but “active coproducers.” They are actively co-creating values with service providers, through which their individual needs are better served and satisfaction enhanced. Ennew and Binks (1999) suggest that participation consists of three broad dimensions: information sharing (CPIS), responsible behavior (CPRB), and personal interaction (CPPI).

2.1.1 Information sharing

Information sharing is defined as the degree to which customers are involved in firm’s Value co-creation to share information stemming from their downstream customers. For successful value co-creation, customers should provide resources such as information for use in value co-creation processes (Lengnick-Hall, 1996). If customers do not provide essential information, employees cannot even begin or perform their duties. Through sharing information with employees, customers can ensure that employees provide the service that meets their particular needs (Ennew & Binks, 1999). For example, taking the car in for service, customers need to give the mechanic information about strange noises or vibrations. Or when ordering a cake for a special occasion, customers should provide adequate information for the flavor and design. Patients should provide the physician with proper information about their condition so that the physician can make an accurate diagnosis. If customers fail to provide accurate information, the quality of value co-creation may be low. Thus, information sharing is the key to the success of value co-creation.

2.1.2 Responsible behavior

Responsible behavior emphasizes a joint problem-solving approach, in which customers and firms work together to accomplish development tasks throughout the Value co-creation (Bonner, 2010). Responsible behavior occurs when customers recognize their duties and responsibilities as partial employees (Ennew & Binks, 1999). For successful value co-creation between themselves and employees, customers need to be cooperative, observing rules and policies and accepting directions from employees (Bettencourt, 1997). For example, customers must follow the employees' directives and be physically present for the successful value co-creation. Without customers' responsible behavior, little value co-creation occurs in the service encounter.

2.1.3 Personal interaction

Personal interaction refers to interpersonal relations between customers and employees, which are necessary for successful value co-creation (Ennew & Binks, 1999). Kelley et al. (1990) use the term customer functional quality to refer to the interaction between customers and employees, which includes interactional aspects such as courtesy, friendliness, and respect. Value co-creation in a service context takes place in a social setting; the more pleasant, congenial, and positive the social environment is, the more likely customers are to engage in value co-creation (Lengnick-Hall et al., 2000).

2.2 Innovation capability

Innovation is often described in terms of changes in what a firm offers the world (product/service innovation) and the ways it creates and delivers those offerings (process innovation) (Francis & Bessant, 2005). While there are many ways a firm can achieve a competitive advantage, two of the most important in dynamic markets are innovation and strategic flexibility (Barney, 1991). Innovation is a critical activity for companies and firms that do not innovate can not eliminate risks from the market. Samson (1991) classifies innovation into three categories: 1) product innovation; 2) process innovation; and 3) managerial and systems innovation.

Based on Samson’s concept of innovation categories, Tasi et al (2001) define a firm’s innovation capability as including product innovation, process innovation, and managerial innovation. The first

definition, product innovation, is that a firm can provide differentiated or new products/services in the market and obtain satisfaction from customers. In this definition, product improvement and new product development which can satisfy customers is the basis of product innovation. This product innovation may include three categories: radical innovation, incremental innovation and system innovation in the new product development process. On the other hand, process innovation is a process in which a firm can provide a better manufacture or service process than current operation in order to achieve better performance. Tasi et al. describe how a method of generating modification or a new process in a current operational step or procedure can offer a capability for innovative process. By doing so, a new process may reduce operational costs or generate more production for a firm. In the same vein, process innovation belongs to the area of technical innovation. Management innovation is a capability that improves a firm's performance by implementing new managerial regulations, systems, and methods etc. Therefore, knowing how to increase a firm's managerial functions and mechanisms in terms of improving managerial efficiency becomes an innovative capability. In this regard, management innovation is the management aspect of innovation.

3 Research Model and Hypotheses

3.1 Information sharing and innovation capability

Several studies have confirmed the effect of information sharing on innovation capability. For instance, Verhoef (2003) and Lagrosen (2005) found that manufacturers can launch more new products and services into the marketplace by using information from clients regarding market preferences, market demands, and market competition. Ottum and Moore (1997) and Souder et al. (1997) also verified that using information provided by clients facilitates the development of more diverse new products and modifications to the functions of existing products to meet the needs of specific target markets. Carr and Pearson (1999) pointed out that information sharing between manufacturers and their clients about markets, designs, and processes enables manufacturers to adopt technologies that can improve design and process innovative capabilities. Overall, there are positive effects of information sharing on product and process innovations.

Intra-organizational information exchange is important for the creation and diffusion of innovations within complex multiunit organizations. Frequent and close interactions allow actors to know each other, share important information, and create common ideas. Hence, an actor that is central in a network of social interactions likely has greater potential to integrate organizational resources (Tsai & Ghoshal, 1998). Dean and Evan (1994) observed that sharing information about market competition, sales promotion, market demand, and market preference enables manufacturers to develop better innovative mechanisms in pricing, sales promotion, distribution, and interaction marketing strategies. Therefore, information sharing has a positive effect on marketing innovation. Lin and Germain (2004) found it is important that customers are willing to provide feedback on their specific needs, such as after-sale services, warranty systems, and claims handling procedures. Manufacturers can follow up on the customers' opinions and feedback to improve their customer service systems. In other words, there is a positive effect of information sharing on service innovation. Accordingly, we suggest the following hypothesis:

H1: Information sharing will be positively related to innovation capability.

3.2 Responsible behavior and innovation capability

Responsible behavior emphasizes a joint problem-solving approach, Joint problem solving is considered as a key factor affecting the success of product and market development. In a joint problem-solving process, the Value co-creation consists of a set of interrelated, specific tasks distributed between the customer and the manufacturer (Von Hippel 1990). The development team can challenge traditional perspectives and discover novel linkages in the development process (Milliken & Martins 1996; Osborn 1963) by connecting different design parameters that have not been linked before or by finding new ways to uncover creative elements (Amabile 1983), which can significantly enhance *CPRB*'s effect on new product innovativeness (Krishnan & Ulrich 2001; Sethi et al., 2001). For example, Von Hippel (1990) argues that finding new ways to connect the design of a car's piston and engine cylinder could improve the innovativeness of auto engine designs.

Ritter and Walter (2003) believed that it would be easier for manufacturers to improve product quality and technical process ability when customers voluntarily provide assistance to solve product design or technical process problems. Joint problem solving influences innovation in that it generally introduces ongoing improvements to existing products, processes, or services, and it exploits the

potential of established designs, processes, and markets (Huang & Chang, 2008). Thus:

H2: Responsible behavior will be positively related to innovation capability.

3.3 Personal interaction and innovation capability

In social network theory, the strength-of-ties literature typically involves both strong and weak ties. Following Granovetter's (1973) description, strong ties are viewed as having a high degree of closeness, mutual trust and reciprocal action of a relationship between two parties, which are more likely to result in sharing of sensitive information than weak ties (Uzzi, 1997).

When customers participate in idea generation during a Value co-creation, they use a variety of cues and feedback to communicate customer preferences and needs through face-to-face interactions, group discussions, meetings and electronic communication channels. Such interaction is more likely to develop a better understanding of the pertinent knowledge possessed by both parties, and to identify what information needs to be shared (Fang et al., 2008), as well as generate an atmosphere of trust, raising inter-organization bonds.

The development project requires trial-and error and iterative procedures to find alternative routines and solutions. In addition, both parties may probe into the application and consequences of new products within the customer's organization (Bonner, 2010). During co-development, however, both parties must meet frequently to build understanding and solve problems (Peters et al., 2010). Rich communication offers important clues that enable interpretation of each party's behavior and motivations, which stabilizes the collaborating relationship and promotes trust (Dyer & Chu, 2000). Furthermore, firms would form new mechanisms to support and coordinate their efforts (Zablah et al., 2005) for identifying how to work more cooperatively and increasing innovation quality (Nambisan, 2002). Taken together, we propose the following hypothesis:

H3: Personal interaction will be positively related to innovation capability.

3.4 The moderating role of power asymmetry

Power asymmetry can have an important effect on the relationship between Customer Participation and innovation capability. Dialog, access, risk-benefits, and transparency (DART) are emerging as the basis for interaction between the consumer and the firm. Dialog is an important element in the co-creation view. Markets can be viewed as a set of conversations between the customer and the firm (Levine et al., 2001). Dialog implies interactivity, deep engagement, and the ability and willingness to act on both sides. It is difficult to envisage a dialog between two unequal partners. When one of the parties dominates the other and forces its views onto the other partner, innovation capability could be negatively affected. In such situations the sharing of data and information which is critical to value co-creation will be difficult or even impossible. Furthermore, Ford and Thomas (1995) showed that in asymmetric relationships communication will predominantly go from the dominating party to the dependent party. The lack of balance in power in turn hampers the dependent party's responses to the dominant party's initiatives. Hence, symmetry in the power situation of two partners is expected to facilitate co-creation experiences, power asymmetry will lead to less customer participation.

From the relationship marketing perspective, business relationships affect a firm's innovativeness and competence. The innovation capability of a firm reflects how successful it has been in combining relationships and its own features. Power symmetry therefore indicates to other firms that a company has the potential to be a strong contributor to co-creation within the relationships. Without the types of symmetry relationships that are considered to make important contributions in value co-creation process and are seen as valuable and distinctive by the other party, value co-creation may be hollow. Interaction with another party in a symmetrical relationship will determine the usefulness of value co-creation and will enhance the capability in which these symmetrical relationships are developed. In so doing, we expect to find innovation capability to be most effective when dyadic power relationship is symmetry. Thus, we propose the following hypotheses:

H4: Power asymmetry will negatively moderate the relationship between Customer Participation and innovation capability.

H4a: Power asymmetry will negatively moderate the relationship between CPIS and innovation capability.

H4b: Power asymmetry will negatively moderate the relationship between CPRB and innovation capability.

H4c: Power asymmetry will negatively moderate the relationship between CPPI and innovation capability.

The above hypotheses are shown in Figure 1. The Hypothesized model will be empirically

analyzed in the next section.

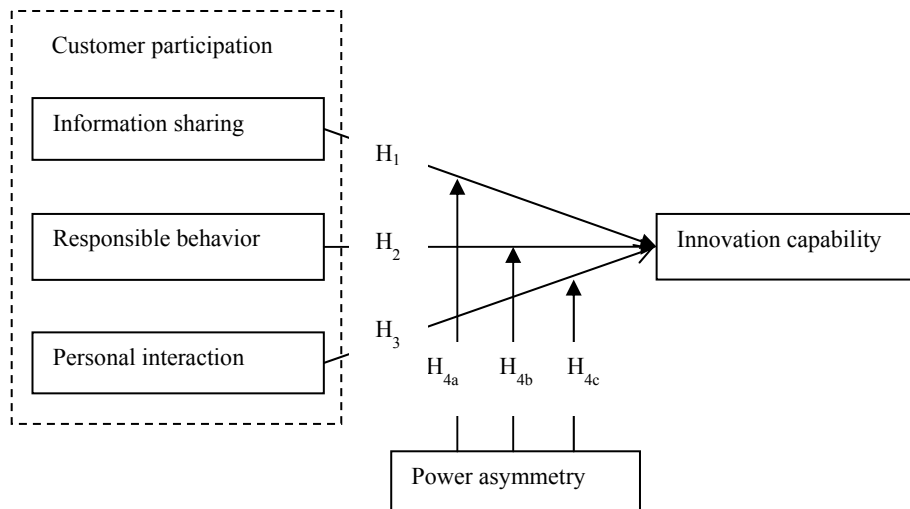

Figure 1 Hypothesized Model

4 Method

4.1 Pretest, sample, data collection

For pretesting, a random selection of 30 CEOs or senior executives was contacted to increase content validity. After obtaining their consent to participate, the 30 CEOs or senior executives were asked to evaluate the draft questionnaire. Based on their feedback, we modified some of the survey questions accordingly. Cover letters sent with the revised questionnaires confirmed the respondents' involvement with customer participation in question, stressed the importance of this research, and offered an incentive (a copy of the finished report summarizing our research findings). To maximize the response rate, we used the mail survey methods suggested by Dillman (1978), including a follow-up letter with an additional copy of the questionnaire sent to non-respondents 1 month after our initial mailings. We also assessed the key informant quality in our survey to make sure that respondents were knowledgeable about the customer participation on which they reported, and then eliminating respondents who were not knowledgeable about the customer participation on which they were reporting. A total of 600 questionnaires were distributed and 256 responses were received, for a response rate of 42.6%. The sample used in this study includes 256 firms in the B2B market of china, as described in Table 1.

Table 1 Distribution of firms

Variables	Number of firms	Percentage
Number of employees		
1-100	77	30.1%
101-300	53	20.7%
301-500	24	9.4%
501-1000	27	10.5%
>1000	75	29.3%
Industry		
Manufacturing	132	51.6%
Service	124	48.4%
Firm age		
1-5 years	38	14.8%
6-10 years	65	25.4%
11-15 years	59	23.0%
16-20 years	15	5.9%
>20 years	79	30.9%

Table 1 provides an overview of the relative distribution of the firms in terms of the following three relevant variables: number of employees, industry classification, and firm age. The largest group of firms has between 1 and 100 employees (30.1%), and 29.3% of the firms that employs over 1000 employees. In terms of industry classification, 132 firms (51.6%) belonged to Manufacturing and 124 firms (48.4%) belonged to Service. The largest group of firms established less than 10 years (40.2%), and 30.9% for firms of over 21 years, and 28.9% for firms between 11 and 20 years of age.

4.2 Measurement and validity

4.2.1 Customer participation

In customer participation, we utilized the work of Yi and Gong (2012) to distinguish three dimensions of customer participation, CPIS, CPRB and CPPI. Through sharing information with employees, customers can ensure that employees provide the service that meets their particular needs (Ennew & Binks, 1999). A new three-item, seven-point Likert scale was developed to measure CPIS. Cronbach's α for these items is 0.91. Responsible behavior occurs when customers recognize their duties and responsibilities as partial employees (Ennew & Binks, 1999). Three items that use a seven-point Likert scale were developed to measure this construct. Cronbach's α for these items is 0.83. In addition, CPPI refers to interpersonal relations between customers and employees, which are necessary for successful value co-creation (Ennew & Binks, 1999). Three items that use a seven-point Likert scale were developed to measure this construct. Cronbach's α for these items is 0.85.

4.2.2 Power asymmetry

The idea of power asymmetry was to see if dependence levels differ in asymmetric relationships when one party is less/more dependent than the other party. Therefore, operationally, there is difference in the dependence levels. Assuming dependence to be the obverse of power, a positive value indicates a power advantage, and a negative value a disadvantage. The three items (see Appendix) to measure dependence were drawn from Lusch and Brown (1996) and Gelderman (2003). Cronbach's α for these items is 0.82 and 0.90 respectively. We use mean of these items to measure dependence. More specifically, we computed the absolute difference between focal firm's dependence on the customer and the customer's dependence on focal firm to measure power asymmetry.

The reliability of each unidimensional scale was examined by computing the reliability coefficient. Convergent validity was investigated by performing a series of confirmatory factor analyses (CFA) at the first-order level. The criterion of all factor loadings being significant at the 0.05 level was used as an indicator of convergent validity. Discriminant validity was assessed by estimating a two-factor first-order model for each possible pair of scales. Thus, three dimensions of customer participation and power asymmetry, and their unidimensionality was asserted using CFA. The CFA fit statistics ($\chi^2=160.08$, $df=80$, $GFI=0.92$; $AGFI=0.88$; $NFI=0.95$; $CFI=0.98$; and $RMSEA=0.063$) indicate an acceptable level convergent and discriminant validity (Joreskog & Sorbom, 1989). After purification, the scales indicated a sufficient degree of unidimensionality, reliability, and validity.

4.2.3 Dependent variable

Innovation capability was treated as a unidimensional construct. The items of innovation capability were extracted from the literature on innovation and innovativeness. Specifically, this study measured innovation capability from the following two aspects: innovation of products and process (Song et al., 2008) and an innovative culture in the organisation, in terms of receptivity and willingness to foster innovation (Wang & Ahmed, 2004). Statements like "In comparison with our competitors in China, our firm has introduced more innovative products/services during the past five years" and "Key executives of our firm are willing to take risks to seize and explore 'chancy' growth opportunities" were included in the survey. Cronbach's α for these five items is 0.91.

4.2.4 Control variables

There are some variables not considered in the hypotheses that may still influence innovation capability. We thus control for some variables that are likely to affect capability, including firm size, firm age, and industry diversity. Firm size, a commonly used control variable often related to diversity levels, is measured by the logarithmic function of number of total employees (Blonigen & Taylo, 2000). This is significant because large firms have more resources invested in R&D, marketing campaigns, and production equipment than smaller firm, they may have greater innovation capability than smaller firms. Firm age, an important control variable, is measured by the natural logarithm of the number of years a firm has been in existence since younger firms often pursue more radical innovations than older firms (Huerger & Jaumandreu, 2004; Geenhuizen & Reyes, 2007). Industry diversity is very difficult to operationalize, and even the data necessary for empirical work are often unavailable or unreliable.

Hence if it is not possible to include these factors in an empirical study, it is especially important to control for innovation capability differences. The industries were divided into 2 different classifications.

5 Results

Table2 provides descriptive statistics and a correlation matrix. The hypotheses were tested by estimating the following equation using ordinary least squares regression:

$$IC = \beta_0 + \beta_1 FS + \beta_2 FA + \beta_3 IC + \beta_4 CPIS + \beta_5 CPRB + \beta_6 CPPI + \beta_7 PA + \beta_8 CPIS \times PA + \beta_9 CPRB \times PA + \beta_{10} CPPI \times PA + \epsilon$$

Table 2 Correlations among Variables (N=256)

	Mean	SD	1	2	3	4	5	6	7	8
1. Innovation Capability	4.77	1.01	1							
2. Information sharing	5.40	1.21	0.52**	1						
3. Responsible behavior	4.84	0.93	0.51**	0.57**	1					
4. Personal interaction	4.75	0.94	0.43**	0.63**	0.52**	1				
5. Power asymmetry	1.20	1.15	-0.05	-0.09	-0.09	-0.20**	1			
6. Firm age	2.60	0.86	0.55	0.03	0.10	0.02	0.07	1		
7. Firm size	2.64	0.94	0.26**	0.07	0.03	-0.05	0.02	0.58**	1	
8. Industry classification	0.48	0.50	-0.07	0.05	0.09	0.13*	-0.16*	-0.20**	-0.26**	1

In order to test this study's hypotheses, we analyzed different models (see Table 3). Using the three models shown in Table 3 helps us to examine the increases the variance explained, which is reflected by an increase in the adjusted-R squared. Moreover, following these steps, we can test for a moderator (Baron & Kenny, 1986) . First, the control variables were regressed in the dependent variable. Our findings are listed in Table 3. From the results presented in Model 1, it follows that firm size yield negative significant result and firm age yield positive result. Therefore, we find supports for differences that pertain to firm size and firm age.

Table 3 Results of Hierarchical Regression

	Model 1			Model 2			Model 3		
	β	t-value	VIF	β	t-value	VIF	β	t-value	VIF
Control variable									
Firm age (FA)	-0.15*	-1.96	1.52	-0.20**	-3.35	1.57	-0.23**	-4.11	1.61
Firm size (FS)	0.34**	4.54	1.57	0.34**	5.60	1.62	0.38**	6.68	1.65
Industry classification (IC)	-0.01	-0.04	1.08	-0.07	-1.37	1.12	-0.08	-1.73	1.13
Direct effect									
Information sharing (CPIS)				0.24**	3.55	1.96	0.27**	4.25	2.01
Responsible behavior (CPRB)				0.31**	5.15	1.62	0.28**	4.90	1.64
Personal interaction (CPPI)				0.15*	2.32	1.85	0.17**	2.80	1.88

Responsible behavior \times power asymmetry							-0.08*	-1.97	1.67
Personal interaction \times power asymmetry							0.22**	3.03	2.62
Adjusted R-square	0.07			0.41			0.49		
R-square change	0.08			0.43			0.51		
F	7.42			37.93			13.30		

Note: * $p < .05$, ** $p < .01$

In testing the hypotheses relating to the moderating effects, moderated regression analysis, as recommended by Irwin and McClellan (2001) , was undertaken hierarchically to test for significant interaction effects over and above the simple effects of independent variables. These tests allow us to

expand on both the importance and the significance of the interaction. The resultant models are shown in Table 3. Model 2, containing the simple additive model, show that respective CPIS ($\beta=0.24, t=3.55, p<0.01$), CPRB ($\beta=0.31, t=5.15, p<0.01$) and CPPI ($\beta=0.15, t=2.32, p<0.05$) positively impact innovation capability. Thus, H1, H2 and H3 are supported, respectively. At the next stage the three interactive terms were added to Model 3 resulting in a statistically significant increase in R^2 . This result reveals that the effects of CPIS, CPRB and CPPI on innovation capability are influenced by the level of power asymmetry. Although the main effect of CPIS was positive, the interaction of CPIS and power

Asymmetry on innovation capability ($\beta=-0.37, t=-5.31, p<0.01$) was negative and significant. H4a is supported. To better interpret our findings, we conducted a simple slope test, as described by Aiken and West (1991). This revealed that, for the slope significance test at low level ($t=7.468, p=0.000$) of power asymmetry, the relationship between CPIS and innovation capability is statistically significant. We used the ModGraph software (2010) and graphed the interaction effects following procedures set forth by Cohen (2003), as shown in Figure 2.

Figure 2 Moderating Role of Power Asymmetry on the Information Sharing-Innovation Capability Link

In addition, the interaction of CPRB and power asymmetry on innovation capability ($\beta=-0.08, t=-1.97, p<0.1$) was negative and significant. H4b is supported. A simple slope analysis showed that at both high ($t=2.661, p=0.008$) and low ($t=4.749, p=0.000$) levels of power asymmetry the relationship between CPRB and innovation capability is positive and statistically significant. Figure 3 shows the moderating role of power asymmetry (high and low levels) on the CPRB-innovation capability relationships.

Figure 3 Moderating Role of Power Asymmetry on the Responsible Behavior-Innovation Capability Link

Finally, in contrast to the hypothesized relationship, the interaction between CPPI and power asymmetry is significant but positive for innovation capability ($\beta=0.22, t=3.03, p<0.01$). H4c is not supported. A simple slope analysis showed that at high ($t=4.808, p=0.000$) level of power asymmetry the relationship between CPRB and innovation capability is positive and statistically significant. Fig 4

shows the moderating role of power asymmetry (high and low levels) on the CPPI-innovation capability relationships.

Figure 4 Moderating Role of Power asymmetry on the Personal Interaction-Innovation Capability Link

6 Discussions

This research examined the effects of Customer Participation on innovation capability. We have further theorized that power asymmetry may moderate the individual effect of Information sharing, Responsible behavior and Personal interaction on innovation capability. Our results demonstrate the need to make a distinction among the three moderating effects. Specifically, we found that the main effects for Information sharing, Responsible behavior and Personal interaction were positive, which largely extends previous research. We argue that, in order to enhance innovation capability, B2B firms must rely on more customer participation in the process of value co-creation. This finding also holds interesting managerial implications. First, when firms co-create value with its customers, the information obtained from its customers can be used to enhance strategy and operations in areas related to the innovative activities. This information sharing effect can constitute the benefits that a firm can earn unilaterally by acquiring innovative information from its customers. The information can be internalized by the firm and applied to innovative activities.

Second, the richer the prior responsible behavior of the customer is, the greater its exposure to various possible integrations with different co-creators is. Adaption should follow, as firms reduce inappropriate co-creator and find good ones. Thus, more extensive responsible behavior allows firms to identify effective processes for exchanging information and technology with their co-creators and for managing complex innovative activities with uncertain outcomes. More specifically, as customers accumulate responsible behavior, they are better able to make adaptations in value co-creation processes to attribute innovation capability. With customers' responsible behavior, firms can adopt better innovative processes to reduce the complicated time-consuming processes. This finding is in agreement with previous studies.

Third, better personal interaction will reinforce interaction between employees and customers, improve the member's openness and acceptance, These are the important psychological atmospheres for exertion of innovation capability. Moreover, good personal interaction will promote knowledge sharing between firm and customer, and benefit to firm's innovation capability. This finding is in agreement with previous studies that knowledge sharing works as an important mediator between personal interaction and innovation.

Most existing literatures implicitly suggest that information sharing is differentially effective, depending on whether the power situation is symmetrical or asymmetrical. Our results certainly do not detract from this view. We expand upon this notion that information sharing is likely to have a negative effect on the innovation capability under higher power asymmetry relationships. The potential explanation for this is that information sharing may have a negative effect when co-creators have imbalanced resources and capabilities in higher power asymmetrical relationships. This is typified in co-creation where one or more partners have more power or resources than the others. Since all parties in value co-creation relationships may face varying degrees of conflict in their interaction with other parties, conflicts may arise from partners' differing expectations in asymmetrical relationships so that goals and cultural norms of one party can eventually clash with those of another.

The implications are straightforward. First, innovation capability may have been underdeveloped in asymmetrical power relationships, or even have lain dormant over a period of time since the focus of

innovation development has been for the stronger partners' benefit. Conversely, weaker parties may lack capabilities in resource deployment and innovative development to assist the creation of new products. Therefore, it may be necessary for the stronger party to provide to weaker parties more new knowledge, specialized skills, resources, and activities.

The second implication is the development of new symmetrical relationships by information sharing and responsible behavior to improve innovation capability. Both parties need to redress the balance of their asymmetry relationship characteristics. Changing the nature of an asymmetrical relationship is not something that partners can do alone. Rather they must learn how to work in value co-creation with their partners, as both parties have influence over the direction of the relationship. Having learned to live with relationships where no mechanism for value co-creation has existed, weaker parties who are more used to coping with asymmetrical relationships with stronger parties may have gained little benefit in value co-creation. Therefore, the ability of learning to change from asymmetrical to symmetrical relationships between co-creators will be critical for creating better performance.

In the literatures, the relationship between personal interaction and innovation capability is mostly positive. Little empirical research has examined what moderators cause contradictory finding. As such, perhaps the most important contribution of this research is the results of our examination of power asymmetry as a moderator of the link between personal interaction and innovation capability. Personal interaction between co-creators with lower power asymmetry will result in less improve of innovation capability than co-creators with higher power asymmetry. A possible explanation for this unexpected finding is that power asymmetry could not be a polar opposite of co-creation. Power can be seen as a mechanism for achieving coordination among co-creators. Despite some critics' view of power as the antithesis of trust, Kumar contends that trusting partnerships can be built between unequal, but only that the onus is on the powerful party to treat the weaker, vulnerable party fairly. Relationships are seldom fair in power, nor are all parties equally active in commitment to a relationship. A general view is that such partnership arrangements tend to offer the most to the more powerful business partner. Therefore, this does not mean that such power asymmetry relationships are not workable or enduring. Moreover, power asymmetry may also be viewed as positive effect, which brings together different co-creators and staff within them with varied views, cultures, strategies and competitiveness.

7 Conclusions

In spite of these important contributions, several research limitations should be recognized to provide a balanced discussion of our findings. First, innovation capability, our dependent variable, might also be considered a type of corporate capabilities, and therefore, the use of innovation capability as a proxy of corporate capabilities might provide a limitation to this study. Future researches should examine other types of corporate capabilities, because customer participation is not only benefit to firm's innovation capability, but might also benefit to firm's other capabilities such as marketing capability, relationship capability, etc.

Second, due to the dynamic nature of the variables in study, customer participation, and power are seldom static and likely to change over time. This is because co-creators during the interactions may react differently depending on the different phases in the value co-creation relationships. Furthermore, another recent research has called for future studies' need to empirically assess the cooperation dynamics in value co-creation. In similar vein, this study employs of a cross-sectional design. In any model in which causality is suggested, longitudinal studies will provide for stronger inferences. Therefore, the proposed model developed in this study could benefit from being tested in a longitudinal design, so that actual situation of variables can be taken into account. Future research should also consider the need for longitudinal research, as longitudinal research designs may be needed to explore how comparison standards change over time, as customer participation along various phases of value co-creation developments. Though there is difficulty in this line of research, but this appears to be a critical area for future research.

Third, although the heterogeneous nature of our sample lends support to the generalizability of our results, there may be significant differences that might have attenuated our results. Had we used a sample that was more homogeneous, perhaps we would have reduced the variance noise, which might have resulted in more explained variance. One significant potential cause of attenuation involves the variables in a study: different industry may have different result of the research. Future research should take into account specific industry of customer participation.

To conclude, this article has conceptualized and tested a model to explain how customer participation influences innovation capability. The study of power asymmetry is still relatively new to

value co-creation research. We hope that this article has contributed to both researchers' and managers' understanding of these complex phenomena.

Abstract: In order to make the analysis of information-based innovation system in Chinese enterprises, confirmatory factor analysis (CFA) is used in this paper. By system design, system establishment, data collection and certification result, the CFA can effectively conduct empirical research on information-based innovation system in China's enterprises. For illustration, the collected copies are 200, and the effective rate of collection is 90%, which has satisfied the requirement that the questionnaire returns-ratio is not lower than 20% in the data investigation. The empirical results show that the information-based innovation of Chinese enterprises can't promote the technique absorbing ability, can't support the enterprise decision function efficiently, and can't improve the internal marketing. IT innovation development has not encouraged the development of organization learning as well as knowledge management. But information-based innovation system can provide foundational theory platform for all China's enterprises so as to promote IT innovation efficiency.

Key words: Technique innovation; Information-based innovation system; Internal marketing; CFA

1 Introduction

The information technique is a kind of technique which regards the calculator technique and the communication technique as core content and may realize the information function. There are twice leaps in 60's and in 80's of last century for information technique development. The one takes place under the environment of industry activity, whose influence is partial; the other takes place under the environment of the information technique and communication technique, and has descended the efficiency of network environment while it brings the profound influence for economy society including industry, government and family^[1].

The so-called "information-based paradox theory" holds the phenomenon which information-based construction can no longer produce direct economic efficiency and even descend the economic efficiency in partial realm. The "information-base paradox theory" is the inevitable phenomenon in the information-based construction process because the information technique and enterprise operation mechanism cannot blend each other deeply^[2]. These six stages include beginning stage, spread stage, control stage, integrated stage, data stage and mature stage. The "information-based paradox theory" usually appears in control stage.

The information technique innovation is the valid means to release the bad affection of "information-based paradox theory" according to experience of west flourishing nations. Chinese enterprises should strength the information technique innovation to get rid of the simplicity of traditional investment which obtain economic performance only by the method of annexing capital, and should put the information technique innovation and all enterprise operation including production, management and marketing together to develop the revolution of information technique function and to deeply dig potential of information technique result by which the enterprise performance and core competence of Chinese enterprises can be improved as highly as possible.

The information technique innovation is a kind of process which enterprise integrates the production constituent and production environment by means of applying information technique result to acquire high economic valuation^[3]. The information technique innovation in China's enterprises include various situation: implying new technique craft, exploring new production with information technique constituent, encouraging the production request related with information technique, acquiring the raw material supply including information technique content, adopting a new thought of information technique change. The system design of information-based innovation is the premise for China's

* This paper is supported by NSF (No.70773001) and Bid Project "Xinjiang SME Internal Control Issues". The project is from Humanities and Social Sciences Key Research Base in Xinjiang Normal University-Enterprise Development Research Center of Xinjiang.

enterprises to carry out information-based innovation strategy.

2 The System Design of Information-Based Innovation in Chinese Enterprises

2.1 The demand analysis of system design

The information-based innovation system can resolve 5 elements: information-based technique innovation, information-based management innovation, information-based market innovation, information-based production innovation and information-based environment innovation^[4].

The information-based management innovation element includes 4 measure indexes: decision ability innovation, performance ability innovation, encouragement innovation and human resource management innovation.

Information-based market innovation element includes 4 measure indexes: marketing outlet innovation, customer demand innovation, internally marketing innovation and CRM innovation.

Information-based production innovation element includes 4 measure indexes: quality management innovation, production adjustment innovation, warehouse management innovation and equipment maintenance innovation. Firstly, the quality management is a kind of important management activity of modern enterprise, which includes quality examination, product examination etc. The modern quality management generally asks for help from precise instrument and complicated process while had to handle with a great deal of data, so it must be supported by information technique to realize the task. Secondly, production adjustment is a kind of complicated project especially for big enterprise, which includes artificial arrangement, allotment, raw material supplying etc. Thirdly, warehouse management is an important content of modern enterprise. A precise or complicated production often contains thousands original parts, and the imperfection of an original material may cause the whole failure of production project. So the warehouse information system usually takes a great role in MIS of enterprise. Lastly, the equipment maintenance is also related with information technique because the important equipment contains information technique more and more and the maintenance and examination of equipment have already completely been placed in automation appearance.

Information-based environment innovation element includes 4 measure indexes: organization structure innovation, entrepreneur spirit innovation, organization learning innovation and knowledge management innovation. Firstly, the IT innovation certainly would incur the reformation of organization structure, and the organization structure would conversely promote the IT innovation. Generally speaking, the organization structure in network ages would gradually become the pyramid form of flat type because the rapid information deliver make many middle levels lost existence condition. Secondly, the entrepreneur spirit provides valid terrace for technique innovation of enterprise. The radical talent of entrepreneur isn't the management to daily business of enterprise, but innovation, namely innovation is the root profession of entrepreneur. Therefore IT innovation is an important mission of entrepreneur in information-based ages. Thirdly, organization learning has become an important target of modern enterprise management and the IT provides the valid means for organization learning because the IT raises the circulated speed of enterprise information and the exchange effect of team members. Lastly, IT also provides valid terrace for knowledge management. Knowledge management is a basic management activity of modern enterprise, which includes knowledge collection, knowledge filtering, knowledge classification, knowledge saving, knowledge conversion, knowledge sharing and knowledge innovation^[5]. The completion of every link cannot get away from the support of information technique.

2.2 The establishment of research system

The information-based innovation system may be established in Table 1 according to the theory analysis.

Table 1 The Information-Based Innovation System

Factor	Indexes name	Indexes content
Information-based technique innovation	Technique exploring (X1)	The IT research achievement promote the technique exploring ability of enterprise
	Technique absorbing(X2)	The IT research achievement promote the technique absorbing ability of enterprise
	Technique application (X3)	The IT research achievement promote the technique application ability of enterprise
	Technique integration (X4)	The IT research achievement promote the technique integration ability of enterprise
Information-based management	Decision ability (X5)	The IT research result improve the decision efficiency of high level managers

innovation	Performance ability (X6)	The IT research result improve the operation efficiency to management directors
	Encouragement ability (X7)	The IT research result improve the encouragement efficiency of enterprise employees
	Human resource (X8)	The IT research result improve the management efficiency of human resource
	Market outlet exploration(9)	The IT research achievement has strengthened the exploration of marketing outlet
Information-based market innovation	Customer demand (10)	The IT research achievement has strengthened the customer demand
	Internal marketing (11)	The IT research achievement has strengthened the function of internal marketing
	CRM innovation(12)	The IT research achievement has strengthened the CRM function
	Quality management(13)	The IT research achievement has strengthened the product quality management ability
Information-based production innovation	Product adjustment(14)	The IT research achievement has strengthened the production adjustment ability
	Warehouse management(15)	The IT research achievement has strengthened the warehouse management ability
	Equipment maintenance(16)	The IT research achievement has strengthened the equipment maintenance ability
	Organization structure innovation(17)	The IT research achievement has optimized the organization structure
Information-based environment innovation	Entrepreneur spirit innovation(18)	The IT research achievement has initiated the entrepreneur spirit
	Organization learning innovation(19)	The IT research achievement has improved the efficiency of organization learning
	Knowledge management innovation(20)	The IT research achievement has improved the efficiency of knowledge management

3 Model Certification

3.1 Data collection

This paper adopts 7 points measure form to collect data for 20 observe indexes, and choose 200 sample from the database of a consult company. All samples should carry out consultation behavior concerning information-based innovation aspect in the last years or once attend the public training public of the consulting company about the IT innovation activity. The sample totality distributes in 13 provinces or autonomous regions so may represent the total circumstance of information-based innovation in Chinese enterprises. This research seeks for data support for these 200 sample enterprise by means of electric questionnaire, mail questionnaire, telephone interview and talking. All visited persons are the CEO, CIO or CKO etc. This inquisition totally takes back 180 valid sample data, and valid recovery rate is 90% satisfying the investigation rule that the recovery rate of valid sample is no lower than 20%.

3.2 Certification results

This paper can certify the validity of measure model of information-based innovation system by the certification factor analysis (CFA). The CFA is a kind of special formation of structure equation model (SEM). The SEM is a kind of mathematics model to analyze the complicated relations of many variables according to the covariance matrix. The SEM may be called CFA when it used for the match certification of theory model to sample data. The ratio of sample number to observer indexes should be more than 5 in the process of SEM.

Table 2 Factor Load

Factor	X1	X2	X3	X4	X5	X6	X7	X8	X9	X10
Load	.37	.08	.22	.34	.11	.38	.17	.12	.24	.67
SE	.07	.07	.10	.12	.08	.06	.06	.07	.08	.12
T	5.2	1.1	2.2	3.1	1.3	5.4	2.9	1.4	3.0	5.4
Factor	X11	X12	X13	X14	X15	X16	X17	X18	X19	X20
Load	.13	.46	.39	.45	.44	.78	1.0	.41	.14	.11
SE	.07	.09	.13	.08	.11	.16	.08	.08	.09	.07
T	1.8	5.01	3.0	5.4	4.0	4.8	1.30	5.0	1.5	1.60

The basic certification implement is the SPSS11.5 and LISREL8.7, and acquires factor loading table such as Table 2 shown. Those load of index in shadow isn't notable. The factor square matrix may be drawn on Table 3.

Table 3 The Factor Square Matrix

	ξ_1	ξ_2	ξ_3	ξ_4	ξ_5
ξ_1	1.0				
ξ_2	0.23	1.0			
ξ_3	0.27	0.30	1.0		
ξ_4	0.31	0.33	0.21	1.0	
ξ_5	0.11	0.19	0.13	0.17	1.0

The match index table can be drawn on Table 4.

Table 4 Match Index

Match index	df	CHI-Square	RMSEA	NNFI	CFI
Current value	150	227	0.054	0.903	0.991
Superior value	—	---	<0.08	>0.9	>0.9

4 Conclusions

Based on factor loading parameter table, we can know that the information-based innovation of Chinese enterprises can't promote the technique absorbing ability, can't support the enterprise decision function efficiently, and can't improve the internally marketing, while the IT innovation development has not encouraged the development of organization learning as well as knowledge management. These problems have high realistic character in the process of IT innovation of enterprise so that enterprise leaders should pay attention to the correlating profession departments.

According to the factor square matrix, we can know that the relativity among elements of information-based system is lower commonly, which express that elements lacks valid support function each other. So the information-based innovation system has obtained certain achievements in Chinese enterprises. Furthermore, the information-based innovation has better match affection, so this system has high usefulness and credibility, and can provide foundational theory platform for all enterprise so as to promote the IT innovation efficiency.

Direction and Principles Research of Risk Transmission in Business Finance System

Deng Mingran, Tang Pingqiu, Chen Yun
School of Management, Wuhan University of Technology, Wuhan, P.R.China
(Email: dmr@whut.edu.cn, chenyun135@126.com)

Abstract: The paper discusses the risk of enterprise financial management system along with the business process chain, interests chain, value chain and fund supply chain to transmit, showing a feather of obvious directions; reveals its transmission is accordance with the principle of unidirectional transmission, bidirectional transmission principle and multi- transmission principles and other characteristics. The paper applies the application of modern financial management theory and methods to predict and control the risk of enterprise financial management system and its transmission by offering guidance for enterprises.

Key words: Business Finance System Risk; Unidirectional transmission principle; Bidirectional transmission principle; Principle of multi-directional transmission

1 Introduction

Business finance system risk transmission principle refers to the direction of enterprise financial management system has some risk of transmission directivity, the risk of enterprise financial management system along with the business process chain, interests chain, value chain and fund supply chain to transmit, showing clear direction and corporate financial systemic risk transmission path dependence. It has unidirectional transmission principle and bi-directional transmission principle and the multi-directional transmission principle.

2 Unidirectional Transmission Principles

From the time series of enterprise finance phases, the uncertainty affects unidirectional transmission from front to back with a role that the uncertainty of the previous phase easily to transmit the risk of enterprise financial management system to the following phases. The fundamental goal of business is to survival, development, the ultimate goal is profit. No matter which level objectives, all require enterprises must have adequate funding. Sufficient amount of money is the basic prerequisites for the enterprise production and business activities, so the fund raising phase will be the corporate finance process cycle starting point. The risk generated in the fund raising phase will be transmitted sequentially along through the following phases. That is, in the fund raising phase, the finance system risk will transmit to the investment phase, and generate the investment risk. Similarly, the uncertainty of the investment phase will affect the uncertainty of liquidity phase and profit distribution phase; the uncertainty of liquidity phase will affect the uncertainty of profit distribution phase. According to the assumption of financial phases, the last phase is profit distribution phase; meanwhile, the profit distribution phase is the end of a funding cycle, but also the starting point for the next funding cycle. According to the direction and principle of the enterprise financial management system, the risk generated from the profit distribution phase may be directly transmitted to the next funding cycle of fund raising activities.

The unidirectional transmission of business finance system risk is not just the sequential transmission from the financial management process, and the risk hopping transmission directionality of the enterprise financial system (as shown in Figure 1). Such as the business finance system risk of fund raising phase may not only generate investment risk, and can be directly transmitted to the liquidity phase by producing liquidity risk, and transmitted to the profit distribution by generating profit distribution risk. Such as, business financing through issuance of shares to raise long-term funds, because of the insufficient and shortage predict from the factors of the macroeconomic environment, industry environment, the issue of time, the issue price, the amount of funds from the market, will fail in issuing shares, funds can not be full mobilization, resulting in the corporate finance systemic risk of fund raising phase, the risk of this enterprise financial management system will not only be directly transmitted to investment phase, and will be directly transmitted to the liquidity phase and profit distribution phase, resulting in a reduction of total project investment, inventories fund funds to reduce the production and profit distribution plan and changes.

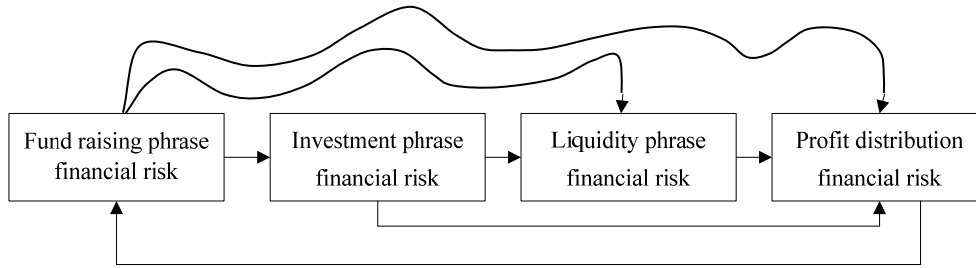

Figure 1 Sketch Map of Unidirectional Transmission Principle of Business Finance System Risk

Note: In this figure, \longrightarrow represents the unidirectional transmission of business finance system risk
 \curvearrowright represents the unidirectional hopping transmission of business finance system risk

The unidirectional transmission of business finance system risk presents a unity direction, the direct transmission influence, a regressive strength and the limitation of transmission range.

- ① Transmission direction unity. Business finance systemic risk starts from a risk source, along established pathways, through a certain carrier transmission to the finish.
- ② Direct influence of transmission. Typically, the two nodes adjacent phase enterprise risk financial systems directly accessible, has a direct impact resistance.
- ③ Transmission strength regressive. In general, the risk transmission of its unidirectional transmission path will not be complicated interference and oscillation nodes affected all aspects of the intercept and obstruct its strength with a monotonically decreasing resistance.
- ④ Transmission range limitation. Bidirectional or unidirectional transmission business financial system risk to the enterprise local area affected by the limited transmission range of business processes in unique business process chain, interests chain, value chain and fund supply chain, has limited its scope.

3 Bidirectional Transmission Principles

In a risk existence financial system, a risk generated from one certain phase is not all risks arising from the previous phase, which is conduct from a previous financial phase to the following financial phase. From the two perspectives of financial management phases, the risk transmission of corporate finance system is reciprocal, that sometimes the risk generated from the next financial management phase may transmit the risk to the previous financial phase, at this time, the risk of corporate finance management system presents bidirectional transmission behavior, as shown in Figure 2. Figure 2 means that, in a time node, fund raising phase fails in raising sufficient funds, resulting in business finance system risk, which may directly transmit to the investment phase, generating investment risk; node at another time, the absence of the expected investment income (especially cash flow) leads to the corporate financial system risk, which bring the failure in producing more incremental cash, resulting in a funding risk. For example, due to the investment in the Giant Building in decision-making, the formation of investment risk is made in the Giant Groups. The result of risk transmission of business finance system is the serious influence in fund hematopoietic function, the Groups had to move more money from the biotechnology industry to the construction of the Giant Building, and finally, resulting in a shortage of funds in the core business.

Figure 2 Sketch Map of Bi-directional Transmission Principle of Business Finance System Risk

The risk bidirectional transmission of business finance system is due to the formation of corporate financial systemic risk between phases with interactive nature of the impact, when the corporate financial system risk transmits to the next phase with a certain impact and losses, meanwhile, the next phase

negative effects immediately feedback on the previous phase, and bring negative effects. Therefore, the bidirectional transmission of corporate finance system risk has four feathers, like reflective transmission direction, convective transmission effect, various transmission intensity and transmission range of expandability.

(1) Reflex transmission direction. Business finance systemic risk starting from a risk source, along with the established pathways, through a certain part of the carrier transmission to the next phase, the result of the next phase is immediately reflected on the previous phase, resulting in mutual influence.

(2) Convective transmission effect. If the risk transmission of business finance system between phases is direct, then the transmission impact is direct, whereas, if it is an indirect transmission, then the transmission between the phases is indirect, with convective.

(3) Various transmission intensity. In general, corporate finance systemic risk is a two-way transmission between phases, the node on the previous phase is the risk source of the next phase, while the next phase node is the risk source of the next phase node, because the thresholds of various risk sources are different, the intensity oscillations are different, it may also be larger or smaller, and therefore the transmission strength is of variability.

(4) Transmission range of expandability. For the bidirectional transmission of business finance system risk between phase nodes, the transmission scope is expanded to the reverse phase nodes than unidirectional transmission range.

4 Principle of Multi-Directional Transmission

In fact, corporate finance systemic risk often presents a complex multi-directional transmission. In corporate financial management system, the financial systemic risks arising from one financial sector may cause some possible simultaneous transmission in various financial sectors (or department). In the interests of corporate financial relationships within the network, one node business enterprise financial system risk may transmit to its multiple financial relationships. Because the corporate financial activities are of recycle financial continuity and the continuous start after the previous cycle. For example, in fund raising activities, the raised funds that are unable to meet basic production operations, foreign investment or the needs of financial structural adjustment funds, will generate a corresponding liquidity risk, investment risk, or profit sharing risks. In the large market environment, the company's financial activities always plays a variety of roles, as investors or creditors or the debtor or other roles. When an enterprise comes across corporate financial systemic risk, it will also transmit to its multi stakeholders, and the stakeholders system risks arising from financial companies will transmit to the outer round network of its own, as shown in Figure 3. Therefore, corporate finance system risks present a rendering complex multi-directional transmission characteristic. This complex multi-directional characteristics of the conglomerate in the performance is particularly evident, because there exists the complex relationship among ownership and the member companies, such as cross-shareholdings between the parent companies, subsidiaries, holding each other, etc., when one related transaction member of the network generates enterprise financial management system risk, the corporate finance systemic risk will naturally be transmitted to the other member companies.

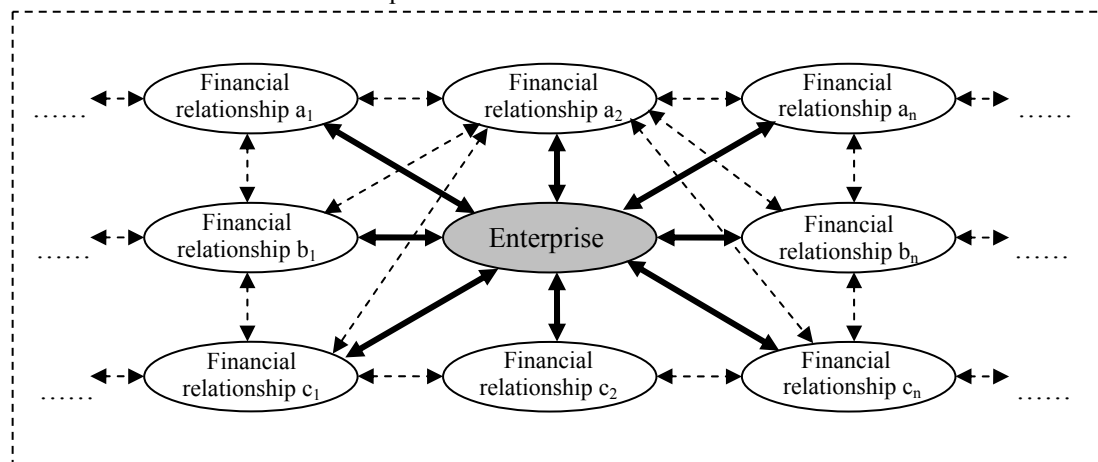

Figure 3 Sketch Map of Multi-directional Transmission Principle of Business Finance System Risk

As Figure 3 shows, corporate finance systemic risk has four characteristics like the multi-dimension of multi-directional transmission, an extensive transmission effect, the non-equilibrium of transmission intensity, and the complexity of transmission range.

(1) Multidimensional transmission direction. Business finance systemic risk starting from a risk source, through staff or business, technology, information and other carriers, at least transmit along with the two or more paths like the business process chain, value chain, supply chain or financial interests chain or capital supply chain, or through people, business, technology, and information transmission carrier, in the business processes, value chain, or financial interests chain or capital supply chain transmission, forming a multidimensional transmission direction of corporate financial systemic risk.

(2) An extensive effect of transmission. Multi-directional risk transmission refers to many pathways, plenty of transmission carriers, with parallel transmission, which makes the impact scope and the influence is much wider, broader and stronger compared with unidirectional or bidirectional transmission.

(3) The non-equilibrium of transmission intensity. As the risk transmission carriers of business finance system are various, the transmission paths are multi-directional, among the transmission carriers, the abilities are quite different to undertake corporate financial system risks, the resistance between transmission paths, and the thresholds are not the same, and thus the intensity of the business finance system risk is non-equilibrium, there is a difference.

(4) Transmission range complexity. Business finance systemic risk starting from a risk source, through diverse transmission carriers, and through multi-directional transmission paths, the operational risk transmission is divergent, uncontrollable, leading to a complex transmission range.

5 Conclusions

(1) The risk transmission of business finance system is of obvious orientation, and follow the principle of unidirectional transmission, bidirectional transmission principle and multi-directional transmission principle.

(2) Unidirectional transmission principle refers to the uncertainty of corporate finance from a previous phase node backwards to the next phase according to a unidirectional transmission, which presents a unity direction, which has the direct transmission influence, a regressive strength and the limitation of transmission range.

(3) Bidirectional transmission principle refers to the enterprise financial management system, a certain risk from the previous phase transmits to the next phase nodes, have been affected and losses, at the same time, the negative effect from the next phase immediately fed back to the previous phase and bring negative effects to the other direction, which have reflective transmission direction, convective transmission effect, various transmission intensity and transmission range of expandability characteristics.

(4) Multi-transmission principle refers to the corporate financial system risks may be transmitted simultaneously to multiple nodes of stakeholders, and the risk brought from the related stakeholders will spread to the outer financial network surrounding itself, and the transmission has a multi-dimensional transmission direction, an extensive transmission effect, the non-equilibrium of transmission intensity, and the complexity of transmission range.

Based on the analysis and command of the direction and principles of risk transmission of business finance system, we can use modern financial management theories and methods from the perspective of the risk transmission of business finance system, to predict and control of business finance system risk, in order to achieve the objective of corporate financial management system, and to improve the purpose of corporate economic efficiency.

Abstract: The LOGO of enterprise reflects corporate culture. What kind of corporate culture does the Apple Corp's LOGO show? What is worth Chinese enterprises especially the small and medium-sized enterprises to learn from? In this paper, through the analysis of the Apple Corp's management to interpret the idea of the LOGO design, the author find that the Apple Corp's corporate culture is a kind of non-perfectionism culture. Combined with the present situation of the enterprise culture construction of China, the author put forward the essence of enterprise brand idea should not be the pink of perfection but should be getting more and more perfect, the essence of enterprise market ideas should not be completely occupying but should be to divide a cup of a thick soup, the essence of thought of business management should not be to let the perfect people do perfect things but should be to let the flawed people do right things, and the essence of business development ideas should not be to walk out after perfection but should be walk to more perfect on the road. On Chinese enterprises especially the private small and medium enterprises, the essence of management thought should be this kind of non-perfectionism, which basing on the imperfect situation, standing on solid ground, works steadily towards the perfect.

Key words: Business Management; Corporate Culture; Perfectionism; Non-perfectionism

1 Introduction

On the corporate culture, few of business are not in pursuit of perfection as the ultimate value pursuit. On the Apple Crop's enterprise culture, few of people don't consider it is a kind of perfectionism corporate culture. The LOGO is the external performance of corporate culture, which underlying design concept reflects the thought of the enterprise management, including brand management, market management, talent management and development strategy management. The Apple Corp's LOGO is a bitten apple.

Although on the interpretation of this LOGO design concept, there are a number of versions, which involves a lot of personages, such as Eve (who is a myth in the Holy Bible), Alan Turing (who invented of the Turing machine), Isaac Newton (who was the most famous classical physicist in history) etc., but most people still are the opinion that it is the performance of perfectionism ideas. These points of view, reflected in many books of studying on Steve Jobs, such as the *iCon Steve Jobs: The Greatest Second Act in the History of Business* by William L. S. and Jeffrey S. Y., (William L. S., 2005) the *Les 4 Vies de Steve Jobs* by Daniel I. (Daniel I., 2011), the *Apple's Philosophy* by Yili, L. (Yili, L., 2011) etc.

It is because of either the Apple Crop's products are too perfect, or Steven Paul Jobs' personal perfectionism, although neither the Apple Crop's products nor Jobs is really the pink of perfection.

This paper will analyze the themes on the opposite perspective. At the same time, combining with the reality of Chinese enterprises especially small and medium-sized private enterprise, to elaborate it is worth learning and reference, and how to learn and use for reference.

2 The Enterprise Brand Idea: Not Perfect, but Gradually Perfect

No product in the world is the pink of perfection. Apple Crop can have today's brilliant achievements, not because of its product is really the pink of perfection, but are constantly in pursuit of perfection. The Apple Crop's products are really very human, very practical, and very beautiful now, which are based on imperfection but gradually improved.

The birth of a brand originally is based on a kind of design concept. Usually, there be gap between the idea and reality. The Apple Crop's most famous brand is certainly the series of Apple mobile phone. From iPod to iPhone4, its products although win in humane, intelligent, and powerful, but the defects

* This paper is the midterm result of the "Research on Western Economic Ethics Thought" (10JZD0021), supported by the ministry of education of China.

also exist at the same time. For example, in the pursuit of their intelligent functions, the basic users asking for the telephone function have been ignored. This resulted in many users attracted by the intelligent function began to use the traditional mobile phone after a period of using it. Another example, until the iPhone4, its EXIT keys for closure procedures is designed hardware return, and this design concept is convenient for the user, as far as possible to make the operation of a fool. However, practice proves, used repeatedly this key by users will cause failure of the key, which has become the major defects reflected by users generally. Therefore, this key will be officially changed to touch soft return in the upcoming iPhone5.

Business create a kind of brand, there are usually some ideas initially. The creation of their brands implies usually that ideal elements are a lot, also problems are a lot. Many enterprises especially small and medium-sized private enterprises completely consider brand as a kind of tool of opening up markets, only in order to protect their existing customers. Operating own brand, to protect and accumulate their own market share. This is a very simple idea, it is nothing wrong, but a series of problems will make the brand survival problems highlighted, on the quality of products, market access, and customer acceptance etc. At this time, many enterprises can't hold on, which either get disheartened, or attempt to transcend the actual strength of the enterprise to work fast, to crash the perfect. It is wrong to do so.

We usually say 'the hundred years brand road', which is not just emphasis on the vitality of the brand, is more on the hard course of brand survival and development. This is a kind of realism thought and culture on brand management. The growth of the brand is like the growth of people. It takes a hundred years to educate people as it takes a hundred years to cultivate brand. In production, in the market, in the business management, to find problems gradually and to solve the problem gradually too, to seek survival firstly and to make development plans then, it is the growth of enterprises, and also is the growth of brand.

3 The Enterprise Market Idea: Not to Completely Occupying but to Divide a Cup of a Thick Soup

The market slogan of many Chinese enterprises, including small and medium enterprises, usually are completely occupied a certain market in their market strategy. For example, the Li-Ning Corp's market positioning is the "winner-take-all in segment market". (Li Chen, 2012) In fact, under the condition of market economy, a kind of product never can occupy fully a certain market in the world. The idea itself of "winner-take-all" violated the market competition concept, which is a kind of monopoly thought in essence, at least is one non-market strategic thinking.

While Chinese society is being in the transition of the economic system, only state-owned enterprises can occupy the system advantage and resource advantage, can make full use of non market strategy in the market monopoly, and make so-called "winner-take-all" finally. This is their habit. However, the private enterprise can't do so. In china, "Compared with state-owned enterprises, private enterprises are faced with more serious discrimination of system of ownership and scale discrimination. This is having private enterprises to be faced with very serious non market environment discrimination." (Wang Fan-jun, 2012) In China, we can say, the market is only a crack in economic society, and private enterprises can only survive in the cracks. In this context, private enterprises should especially carefully consider their market ideas. Before to make own brand, Chinese private enterprises most are intermediate traders, whose philosophy is acting brand of others, fumbling own market. After having mastered the core technology, having owned a certain customer groups, they will be going to make own brand. Both of middle traders and independent brand owners should gradually develop customers, in order to divide a cup of a thick soup in the market in the fierce competition. If the market or client is also seen as an apple, their aim is to try to bite off a piece of apple.

Many private enterprises in intermediate trade have this kind of train of thought in fact originally, but once they begin to do their own brands, immediately forget this idea. During trade, they think it is very happy that, when the others fight for their meat, they can drink a cup of soup by themselves. This is because those brands are not their own, they did not and also could not completely occupy the market. Once they begin to do own independent brands, it seems that they were ambitious about, and they couldn't remember who themselves are. Not consciously, they begin to try to fully capture the market and to treat it as their marketing idea. This is a kind of emotional marketing thought, which is extreme and not practical, easy to toss out own business.

From the middle of the trade to manage own brand, there is no difference about the marketing and sales. All is but to have a little soup in the market, to take a bite of the apple from customers. As for how

much the bite is, this is not a problem, which all is the target, depending on customers and their own ability to decide. But don't want to eat the whole apple, or to drink a bowl of soup alone.

In reality, almost all the customers are not possible using products of only one brand. Is very simple, customers will ask to compare products quality and price. If your customers are individual citizens or the private enterprises, they have to consider the products quality and cost, it is no doubt. Even if your clients are the state-owned enterprises or government administrative institutions which not care about the price and the quality, and even if your non-market resources and capabilities are extremely strong, they are unlikely to only use products of a certain brand, decided by the internal complex network of relationships and the background of national anti-corruption efforts have been stepped up, unless the leaders want to expose corruption insider by themselves. Inside the state-owned enterprises, the leaders whose levels of leadership are high usually know how to balance the internal and external relations, which external appearance is to balance the use of various brands. This also is able to be called "to do something of market by a kind of non - market way".

No matter how strong the Apple Crop under the background of free market is, nor may occupy all of the mobile phone market, not to mention the small and medium-sized private enterprises under the background of non-free-market.

4 The Enterprise Management Idea: Not to Let the Perfect People Do Perfect Things but to Let the Flawed People Do Right Things

Jobs is not be the pink of perfection, as a famous "No. zero employees", who were fired by board meeting once upon a time, although he himself was a perfectionist. It shows the Apple Corp don't pursue the perfect concept in respect of choose and employ persons that he was able to return to the Apple Crop, and to take the reins of the company to brilliant, until died. (Walter Isaacson., 2011) This is a kind of non-perfectionism concept, don't seek perfection, but to the right.

The internal management of enterprises especially the small and medium-sized enterprise, doesn't pursue to reach a pink of perfection, because it can't be done. Nobody is perfect. It is the only reflection of the management level to enable each person to develop his talents, to enable problems to be solved eventually, and to enable efficiency to be improved. Both of Complaining about the strength of the company and complaining about the employee's ability have no meaning. We should do is one thing, to find flaws and shortcomings, immediately try to make up for, to solve the problem, to complete the task. This is the kingcraft of enterprise management.

The enterprise management should allow and inclusive employee's mistakes, because it can only lead to progress, improvement and development that mistakes can expose problems, and problems can be solved. Of course, tolerating mistakes of employees are not let them slide or drift. Cultivating rule consciousness through system education is the best teacher. Employee's behavior is to rely on a system to restrain and regulate, and correcting error is based on rules and regulations. No provisions of the system, we should draw up and improve the system. The improvement of management is embodied through the improvement of system finally.

To ascertain where the responsibility lies also rely on a system. Inside many enterprises, especially state-owned enterprises, the atmosphere of rule by man is very strong. The staffs only are afraid of the curse of leaderships, not afraid to break the rules. This is because after the problems and mistakes have been exposed, the managers deal with not according to the system but according to the views of the leadership. The inevitable consequence is that the system exists in name only, the staffs fear leadership, the public attitude for or against, a sheet of loose sand, and the end result is unmanned responsible. Since employees defer to leadership advice, he will be naturally in the right and self-confident to ask leadership to be responsible. The leader liking what I say goes usually is not willing to be responsible person. So, finally everyone is without any responsibility. In any place, whether a country or enterprise, rule by man always is inefficient and failure. The enterprise must be the rule of law. No matter how uneven is the quality of the staff, as long as everyone observes discipline, freely acts in the frame of system, gives full play to the initiative and creativity of individual, the management will be efficient. So, what we should pursue is not the people are perfect, but the system is perfect.

It is surely the essence of the enterprise human resource management that let non-perfect employees do his best in a perfectly reasonable regime.

5 The Enterprise Development Idea: Not to Walk out after Perfection but Walk to More Perfect on the Road

From computer to the intelligent mobile phone, the Apple Corp always works steadily forward, and its' brilliant is on the way not at the end of the road. In term of the series of Apple mobile phone products, from iPod to iPhone5, although the quality always is being improved gradually, and is heading for perfect gradually, even the telephone function of the new iPhone5 still exists defects, which the call quality less than professional mobile phone, but the Apple Corp always adheres to the improvement of product quality, to pursue more perfect.

The development of enterprises is not and can't be in one step. Especially the small and medium-sized private enterprises which not share policy dividends and system dividends, do not have resource advantage, which result to shortage of funds, lack of talents, technology is weak, must have a right and pragmatic view of development. For them, it is the essence of development to discover and solve problems step by step, gradually go to perfect.

The confidence and patience of enterprise development is not reflected by go to extremes. Dare to invest, dare to employ non-perfect employee, dare to let them make mistakes and correct the mistakes, dare to face and solve problems, dare to overcome all difficulties to promote the product development and market development, it is the embodiment of confidence and patience. On the contrary, such as go back as soon as encountering difficulties, complain about the actual strength of the enterprise as soon as encountering difficulties, change established policy as soon as encountering perplexity, these extreme thought and practice is the performance of no confidence and no patience.

To overcome the thinking of perfection in one step or hesitating to go forward, only so can the enterprise go to developing. The scenery is on the way, not necessarily in the end. The improvement is a process, no end. Therefore, we should learn from the Apple Corp's operating philosophy, which the apple is bitten, we must walk on the road to bite new apples.

6 Conclusion

Many people believe that the essence of the Apple Corp's enterprise culture is perfectionism. But through the analysis of this paper, we can see clearly, the bitten apple is not perfect in fact. Neither Jobs himself nor his apple products' design is the pink of perfection, neither the Apple Corp's idea of management nor its' products is the pink of perfection, just as neither anybody nor anything in this corporate is the pink of perfection. Non-perfectionism is an inexhaustible source of Innovation. Not perfect, but will be more perfect, just as there is no best, only better in the world. So, it can be called non-perfectionism corporate culture.

The pink of perfection is the target, non perfection is the process. Perfectionism would be realized based on non-perfectionism.

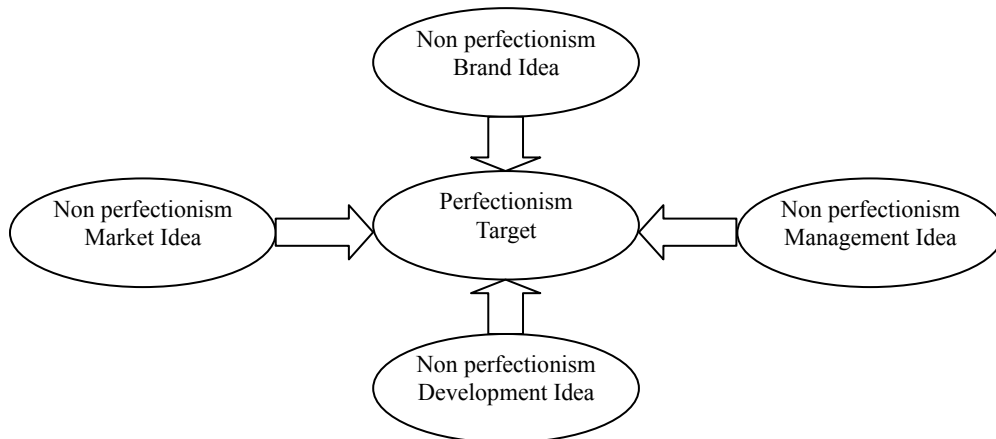

Figure 3 Perfectionism Target and Non-Perfectionism Process

The essence of the underlying design concept of the bitten apple's LOGO is non-perfectionism, and the essence of this kind of non-perfectionism is a kind of realistic corporate culture, and also a kind of free market economy culture, different from the majority of Chinese enterprises, which corporate culture have usually no real value pursuit, would be more like empty slogans or would be more like the government's declaration.

So, on the Chinese enterprises, especially the private small and medium enterprises with no resources, no capital, no brand quality advantages, with discrimination and extrusion of system and

policy, to be worthy of study and reference is not only the non-perfectionism idea but also the realistic culture and the free market economy culture particularly. Away from the state-owned enterprises' non-market thinking, standing in a free market perspective to design culture strategy of own corporate, it is especially important.

Abstract: Misappropriation of public funds as private department coffers has become a serious and intractable corruption phenomenon in China. The enormous losses are caused by misappropriation of funds, the mis-administration of assets, the mis-regulation of the regulator and so on. In this paper, behavior motivation and game theory will be applied to analyze the mechanism of the misappropriation behavior. The analysis suggests that it should construct Long effect mechanism frameworks to restrain the violation of misappropriation actors, on the basis of effective countermeasures discussed.

Key Words: Misappropriation; Behavior motivation; Game theory; Long-Effect mechanism

1 Introduction

The misappropriation refers to the fraudulent appropriation of public funds as private department coffers and not listed in accounting book by regulation, but actually owned by group and should be charged to an account. The misappropriation behavior will seriously debase standards of social conduct, trigger the duty crime and disrupt the market economic order, causing the loss of state assets. In fact, it has become a conservatory for corruption and economic crimes.

In developed countries, because of fairly complete management mechanism, misappropriation behavior is not a prominent social issue. Many of the domestic scholars have studied the reasons of the misappropriation formation, but few on the mechanism analysis of the issue, consequently the countermeasure proposed is not systematic and long-term. China has launched nationwide campaigns to govern the misappropriation behavior, respectively in 1989, 1995 and 2009. From the effects of these activities, the regular governance is effective over the short term, however good times would not last for long and go back to the same situation. Therefore, it is very necessary to analyze the mechanism of misappropriation behavior and construct long-term control system of it.

2 The Mechanism Analysis of Misappropriation Behavior

2.1 The mechanism of misappropriation behavior based on behavior motivation

Misappropriation of public funds defines an intentional action to establish misappropriation in violation of financial control system and relevant regulations. Any activity has certain motives, and the establishment of misappropriation is no exception (Michaelson, Christopher, 2005). We use the motivation theory of Victory Vroom, who is a famous psychologist and behavioral scientist, to illustrate the misappropriation behavior as follows: the motivational force (M) of taking an action depends on the valence (V) of the action target and the expectancy (E) to reach the target. The formula is shown below:

$$\text{Motivational Force } (M) = \text{Valence } (V) \times \text{Expectancy } (E)$$

Valence refers to the value of establishment of misappropriation for the violators meet personal requirement. The larger the requirement is, the higher the valence is. Expectancy is the possibility of misappropriation action subjectively, which is decided by individual and environment factors, but mainly the subjective judgment of actors. Motivational Force interrelates the subjective effort of the individual work on their goals, or other the direct driving force for people to take certain action. Specific to misappropriation behavior, it refers to the extent of the individual's willingness to take misappropriation action.

Motivation Theory shows that the higher the valence of misappropriation behavior (V) and the expectancy (E), the larger the motivational force (M). Under the force, people are more likely to act misappropriation behavior. Therefore, following options can drive people to take misappropriation action: 1) intensify the expected value of violation of misappropriation actors (V); 2) increase the expectancy of establishment of misappropriation (E).

2.2 The mechanism of misappropriation behavior based on game motivation

Misappropriation behavior, not only has relationship with self-motivation of establishers, but also

has something to do with the game of its regulators. Therefore, it is necessary to further study the interaction between the regulators behavior and the fund misappropriation behavior based on the game model.

1) Basic assumptions

Assumption 1: Regulators and the misappropriation actors are rational actors, and pursue the maximum of their own interests.

Assumption 2: The game is between regulators and the actors of misappropriation. Regulators' strategy space is {regulatory, non-regulatory}, misappropriation actors' strategy space is {violations, non-violations}. A mixed Nash equilibrium exists between the two.

Assumption 3: Information asymmetry exists between the regulators and the misappropriation actors, as misappropriation actors know their behavior trends, but regulators rely on subjective judgment to estimate the violation of misappropriation actors.

Assumption 4: the actions taken by the regulators and the misappropriation actors are testable, and the gains can be measurable.

Assumption 5: As long as the regulators execute their supervision, they will find the violation of misappropriation actors, otherwise, the violation can't be found.

2) The establishment of the game model

Assume that the utility is -R if misappropriation is found and is subject to a fine; the utility is S if regulators don't supervise and violation does not exist; if regulators execute their supervision and violation still exists, regulators have a negative effect - C, and misappropriation actors have the utility of U; if violation of misappropriation does not exist, then no gains or losses are recorded for regulators and misappropriation actors. As shown in Table 1.

Table 1 The Game Payoff Matrix of the Regulator and the Misappropriation Actors

		Regulators	
		Not Regulatory	Regulatory
Misappropriation Actors	Violation	U, - C	- R, 0
	Non-violation	0, S	0, 0

3) Solving the game model

There is no pure strategy of Nash equilibrium, but only mixed strategy of Nash equilibrium for the game showed in table 1. And neither can make self-beneficial choices based on opponent actions, so that the balance is achieved when they choose two alternative strategies based on random probability distribution (Malueg, David, 2010).

Let's assume that the probability that regulators choose not regulation is p_1 , and select regulation is $1-p_1$; the probability that misappropriation actors choose violations is p_2 , and select not violations is $1-p_2$. Mixed strategy equilibrium is calculated as follows:

Regulators expect to benefit

$$\begin{aligned} \pi_1 &= p_1[p_2(-C) + (1-p_2)S] + (1-p_1)(0+0) \\ &= p_1[p_2(-C) + (1-p_2)S] \end{aligned}$$

Regulators' goal is to maximize the expectation value, so derive the above formula:

$$\frac{d\pi_1}{dp_1} = [p_2(-C) + (1-p_2)S]$$

Setting it to zero, we have:

$$p_2^* = \frac{S}{S+C} \tag{1}$$

Misappropriation actors benefit

$$\begin{aligned} \pi_2 &= p_2[p_1U + (1-p_1)(-R)] + (1-p_2)(0+0) \\ &= p_2[p_1U + (1-p_1)(-R)] \end{aligned}$$

Misappropriation actors maximize their expectation value, so derive the above formula:

$$\frac{d\pi_2}{dp_2} = [p_1U + (1-p_1)(-R)]$$

Setting it to zero, we have:

$$p_1^* = \frac{R}{R+U} \tag{2}$$

4)The analysis of the game model

Equations 1 and 2, respectively, shows that a mixed equilibrium of the game is achieved when the probability that regulators select dereliction of duty is p_1^* and the probability that misappropriation actors violate the rules is p_2^* . This conclusion shows that the best strategy of one player depends on the other's benefit. The following Figure 1 and Figure 2 further analyze the interaction between the main game players.

Figure 1 indicates a mixed strategy of misappropriation actors. The vertical axis from S to-C is the expected value of violation of misappropriation actors. As corresponding regulatory supervision probability p_2 , p_2^* is the best probability for violation.

Figure 1 The Mixed Strategy of Misappropriation Actors

In order to evaluate the result of punishing the undutiful regulators, the regulators' negative effect should be increased from C to C', equivalently the distance from -C to -C' in Figure 1. Assume that violation probability p_2^* is fixed, the expected utility of regulators is negative, then regulators must execute their supervision and find violation of misappropriation actors, the utility is -R. Provided the regulators fulfil their duty, it would reduce the probability that misappropriation actors violate the rules to p_2^* , constituting the new mixed strategy of Nash equilibrium for the game. It illustrates that increasing penalties for delinquent regulators would make them hardworking for a moment, meanwhile in the long run, the violation probability of misappropriation actors would truly reduce without more dutiful regulators.

Same method can be applied to analyze the probability distribution of dutiful and delinquent regulators. Figure 2 indicates a mixed strategy of regulators.

Figure 2 The Mixed Strategy of Regulators

Aggravating the punishment of misappropriation actors, the negative utility of them should be increased from R to R' , equivalently the distance from $-R$ to $-R'$ in Figure 2. Assume that the probability that regulators select dereliction of duty p_1^* is fixed, the expectancy of misappropriation actors is negative, and then in the short term there will be no violation. The probability distribution of misappropriation behavior is shown in Figure 1 and has no relationship with R . Therefore in the long term, aggravating the punishment of misappropriation actors can do nothing but make regulators slack, until the probability of dereliction increases to p_1^* . The new mixed strategy is constituted.

3 The Long Effect Mechanism of Misappropriation Behavior

3.1 The countermeasure of misappropriation behavior based on behavior motivation

With converse thinking, we can apply the motivation theory to restrain a certain behavior. That is to say, lower the valence (V) or the expectation (E) to restrain the relevant behavior. For this reason, to lower the motivational force of misappropriation should begin with two aspects: valence and expectation.

1) Reduce the valence of misappropriation behavior in the following ways: enhance the education and training for related people; improve the consciousness of laws and disciplines; reward the observer; make leading cadres and staffs realize the seriousness and perniciousness of misappropriation problem.

2) Increase the cost and difficulty of misappropriation behavior. The root-cause of misappropriation behavior is the faulty system and inappropriate implementation. The loopholes increase the valence and expectation of violator to a large extent. For this reason, to eliminate the private behavior form the source, a sound financial system must be established to reduce the assets operation space; then, strengthen the execution of system to make the misappropriation owners accomplish nothing.

3.2 The countermeasure of misappropriation behavior based on game theory

The analysis based on Game Theory shows that tougher punishments can only get a short-term effect, but make regulators slack in the long run, which leads to the rebound phenomenon of misappropriation. So, the punishment for regulators' slack works on the real Long effect, rather than the misappropriation actor's violation. Therefore, to have both a long-term effect and a short-term effect, we need punitive measures for both misappropriation owner and the regulator. The specific countermeasures are as follows:

1) Establish and improve the internal control system. No matter the punishments for misappropriation actors or regulators should based on a sound system. Otherwise, it will lose the basis of supervision and authority of punishment. Therefore, establishing a thorough internal control system is the foundation of effect mechanism.

2) Constructs a system of monitor from internal supervision to the superior supervision, financial supervision, disciplinary supervision and mass supervision. For internal supervision, the regulators may slack result from self-orientation. And in consider of the cost, superior supervision, financial supervision, disciplinary supervision can not reach every aspect of the problem. However, mass supervision has the advantages of universality, publicity, specificity and diversity. It not only can be a complementary supervision, but also can monitor the other mode without a break. In conclusion, building such a supervision monitor plays a pivotal role in the long-term mechanism of misappropriation behavior.

3.3 The long effect mechanism frameworks of misappropriation behavior

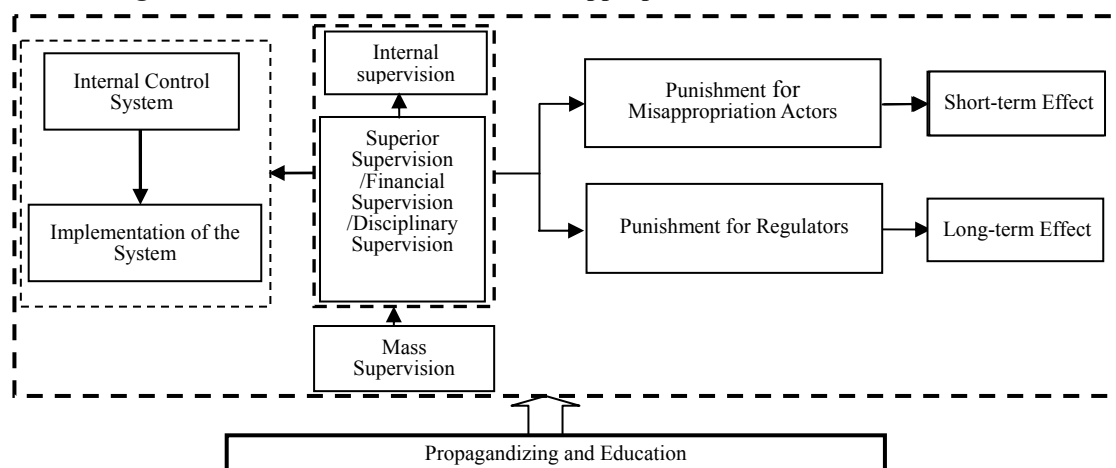

Figure 3 The Mechanism Framework of Misappropriation Behavior

The effective mechanism of misappropriation behavior should build a sound internal control system as a basis, strengthen the supervision as main point, and be supported by resentful propagandizing and educating work(Ma Guoxian, 2011). The long-effect mechanism framework is shown in Figure 3.

4 Conclusion

From the perspective of individual behavior, to lower the motivational force of misappropriation should reduce the valence and expectation of misappropriation actors. Meanwhile, the punishment for regulators' slack can really work for long-term governance in game perspective. Punitive measures for both fund misappropriation actors and the regulators are respectively integrant factors for short-term and long-term governance of misappropriation of public funds as private department coffer.

In conclusion, the effective mechanism for governing misappropriation actions should be built on a sound internal control system, a forceful supervision system as well as propagandizing and education.

Abstract: This paper deals with the different concepts of culture and its impact in organizational management, based on the classical worldwide survey of social cultures and management by Geert Hofstede at the IBM a decade ago. Although, the paper discusses different concepts of organizational culture and social. The work concludes that more and more investments in training and development of the employees will be required, as a matter of survival for global companies. This paper represents a contribution updating the Hofstede's idea and discussing new alternatives.

Key words: Culture ;Organizational Culture; Social Culture

1 Introduction

The evolution of organizations to an organic model instead of the mechanistic model places individuals as the key to business success. The people are the essence for positive results in different processes, because they have the ability to reflect, learn and interact, which means that they create, acquire, transform, and share knowledge.

We know that each individual carries a rich cultural background, from the social environment and different life experiences. Science demonstrates that culture is acquired, excluding the hypothesis of genetic inheritance (HOFSTEDE, 2003).

Cultural difference of the individual manifest in different ways. The concept of culture can be categorized into four types: symbols, heroes, rituals and values (HOFSTEDE, 2003). Just as people have different cultures also organizations and their departments have different cultures. Thus there will be so many cultures as so many organizations in our society.

For at least 30 years ago, the culture is no longer a specific theme of anthropology or sociology, became subject of business schools, economics and management (MIGUELES, 2003). Thus it is understood that "culture is complex. It is not limited to an artistic, economic or social perspective. It is the combination of all these vectors" (BRANT, 2009). In the same way, Skinner (1965, p. 15) notes that "the behavior is a difficult issue, not because it is inaccessible, but because it is extremely complex. Since it is a process, not a thing, cannot be easily immobilized for observations. It is changeable, fluid and evanescent".

The study of culture has been a fruitful field for the understanding organizational phenomena, especially in the modern environment, with increased competition between companies and the emergence of complex processes, such as organizational change, internationalization, mergers and acquisitions and succession.

This article aims to discuss the different concepts of culture and its influence in organizations, analyzing the impact of local culture in internationalized companies, through literature review, relying on renowned authors as Hofstede (2003), Morin (2009), Migueles (2003), Santos (1998), Schein (2009), Brant (2009), among others.

2 The Culture and Its Organizational Influence

The culture has a large impact on the behavior and development of organizations. However, before discuss the concept of 'organizational culture', we need a better understanding of 'culture'. Thus, emphasize the argument of Lacerda (2011) which reinforces that the "*culture only makes sense in a collective and not individually*".

On this point we highlight the understanding of culture by the renowned researcher Schein (2009): "The culture may be defined as a standard of basic shared assumptions, such that has been learned by a group as they solved its external adaptation problem and internal integration. This pattern has worked well enough to be considered valid and therefore to be taught to new members as the right way to perceive, think and feel in relation to those problems."

It is clear, then, the connection between culture and the sense of community, representing the characteristics of a particular group, a locality or a population. The writer Brant (2009) points out that "*the cultural identity of a people is generally recognized for its unifying elements such as territory,*

language and religion".

Therefore, it is clear that culture defines everything that is produced from human intelligence. It is present from primitive peoples in their customs, systems, laws, religion, arts, beliefs, myths, moral values, turning and changing until today, present in everything that affects the feeling, thinking and acting of people .

In this sense, the philosopher Morin (2009) provides three interdependent dimensions to the word culture: the anthropological, or "*everything that is socially constructed and that individuals learn*"; the social and historical, which may be understood as the "*set of habits, customs, beliefs, ideas, values, myths that are perpetuated from generation to generation*"; and the last related to the humanities, which "*covers the arts, letters and philosophy*".

Therefore, it is clear that the 'culture' is derived from a mental programming. Hofstede (2003) argues that mental programs vary as much as the social environments where they are purchased. Given this, placing the focus on organizations, the said author notes that organizational culture can be defined as a "*collective programming of the mind which distinguishes the members of one organization from another*", or similarly, a "*collective mental programming that distinguishes one group or category of people from another*" (Hofstede and McCrae, 2004, p.58).

The referred author Schein (2009) supplementary characterizes the organizational culture into three levels: 1) artifacts - understood as visible organizational structures and processes, 2) values- which are the strategies, goals and philosophies; 3) assumptions - that refer beliefs, perceptions and thoughts, often unconscious.

In this scenario, it is clear that the knowledge of an organization comes from the integration of knowledge of different individuals. Therefore, it is known that one of the biggest problems companies relates to the articulated way to manage this tangle of knowledge to the company to obtain competitive advantages. In other words, "organizational knowledge by itself does not exist, because it arises from the sum of the knowledge of the individuals in the organization" (TEJERA OF RE et al., 2007, p. 2).

It should be emphasized that the organizational culture has different levels of intensity, as argued by Santos (1998): "Cultural force is defined in this study as the extent to which the values and beliefs that permeate the organization are broad and intensely shared by its members. The model estimates that the strong culture is one which incorporates the features over all four types of cultural"

From this point, develops instruments aimed for the organizational culture and the knowledge management, so that organizations resolve bottlenecks and obtain success.

Dealing with instruments, highlights the valuable work of Quinn and Kimberly (1984), which define a cultural typology that aims to organize the different patterns of behavior, values and shared beliefs that define the culture of an organization. Using the juxtaposition of its two main dimensions, emerges four types of culture which characterize the 'Quinn's Culture Type', also known as model of Competing Model Value (C.V.M). The diagnosis is translated by means of an instrument for defining the four types of organizational culture - group, innovation, rational and hierarchical. With these four types of culture can be interpreted attributes and studied the culture of an organization in comparative terms.

Below, it is described a brief explanation of each one:

Group culture: it is based on norms and values associated with affiliation, emphasizing human resource development, valuing the participation of members in decision making and facilitating interaction through teamwork.

Culture of innovation: characterized by assumptions of change and flexibility where the key factors for motivation consist in growth, in the stimulus, in diversification and in the creativity in the task. Leaders tend to be entrepreneurs and idealists, to assess the risk and forecast future, worrying about obtaining resources and the external image.

Hierarchical culture: it is rooted in the values and norms related to bureaucracy, where the basic assumption is the stability and individuals accept the authority of enacted rules and regulations imposed. The motivation is derived from security and order. The leaders are conservative, cautious and targeted to the problems of a technical nature.

Rational culture: it is permeated by assumptions of achievement, based on the belief that the rewards are related to the results. The motivating factors derived from the competition and achieving predefined results. Leaders to drive guided to goals and encouraging productivity.

Finally, it is clear that each of these variables has its blind spots, but also its benefits. Manager shall diagnose and implement the changes necessary to reach the goals and plans outlined by your organization.

3 A Debate on Social Culture

Nowadays, with the evolution of globalization through the heavy flow of people and information, the regional boundaries, physical and cultural are diluted quickly. The process of globalization has established integration between countries and people around the world. Through this process of internationalization world, governments and businesses, exchange knowledge, conduct business transactions and disseminate cultural influences to all corners of the planet. Like any other social phenomenon, globalization has brought positive and negative results for the world, but of this article will be focused on the cultural theme.

One of the risks of the culture globalization is the influence and domination of the richest cultures on the poorest, implying in a possible homogenization of organizations and society. Brant (2009) points out that: "The culture increasingly homogenized, results from a certain cultural hybridism of the global society, able to act with the same intensity and strength of command in societies as diverse as Brazil and Iraq, for example. In this global environment, the question of identity assumes other characteristics"

However, initiatives of international agencies seek to protect cultural identities, as the Convention on the protection and promotion of diversity of cultural expressions within UNESCO, which consolidates the historic struggle against cultural homogenization promoted by a North-American oligopoly formed by business groups, which gather media conglomerates and electronic equipment manufacturers (BRANT, 2009).

On the other hand, cultural differences can facilitate or obstruct business transactions, imposing managers the need to know the differences between people and their cultures. "The cultural differences, which were perceived in commercial situations or travel, for example, now have larger implications. These implications are amplified according to the growth of multinational companies (Brazilian or not) and are expressed in business activities that involve different cultures (in the broad sense, between countries, companies and regions, for example). Although differences exist, the ways in which organizations can treat them, on one hand, be a factor in the creation of a competitive advantage or, on the other hand, make impracticable the international operations, the industrial operations or other organizational activities." (Lacerda, 2011)

After the construction of this synthesis on globalization and its implications we bring to light the influence of local cultures in organizations with internationalized operations. Even with well-defined policies and guidelines pre-established at its headquarters, the question is whether or not there variation in the organizational culture in the different countries where the organization operates. In this sense, the sociologist Inazawa (2009) reports that: "Organizational culture is a very broad and complex topic, which influenced as much the culture of the individuals who work in organizations, as the culture of the country in which organizations are. Without exhausting the subject, we tried to emphasize the issue of organizational culture itself and its relationship with the success of Knowledge Management. Regarding the organizational learning, that was presented as an alternative to flexible organizational culture and facilitates processes of knowledge management."

In the same way, the author Lacerda (2011) emphasizes that: "The distinction between the organization and the country is apparently necessary because, in the current context organizations have transnational character with different types of shareholders and employees. Thus, although physically located in a region, the organization can present distinct characteristics of that place."

At this point we highlight the research of the renowned psychoanalyst Geert Hofstede, portrayed in the book *Culture and Organizations*. In his work, the author demonstrates that national cultures differ from one another in five dimensions¹, which impacts on the culture of organizations depending on the country where they operate.

The cultural dimensions defined by Hofstede originated in a survey research conducted at IBM and its subsidiaries in different countries (Hofstede, 2003). The survey covered 71 countries and was conducted between 1967 and 1973, and all 117 000 remarks (questionnaires) were obtained. Different validation stages of the research were carried out. At this point, as briefly discussed, Hofstede (2003) has shown that national cultures differ according to five dimensions:

Power distance: is the tolerance level of the less powerful members of organizations and institutions to accept this situation, the power is distributed unequally. Thus, it is clear that power and inequality are fundamental facts of any society.

Uncertainty Avoidance: deals with the tolerance of a society in relation to the ambiguity. Indicates the degree to which a culture feels comfortable or uncomfortable in unstructured situations.

¹ After this work, Geert Hofstede came to what he called sixth dimension, available in www.geert-hofstede.com.

Unstructured situations are unknown, surprising and different than usual. Cultures that try to minimize the uncertainty avoid the possibility of such situations by strict laws and regulations. On the one hand, to avoid the uncertainty cultures are emotionally nerve. On the other hand, the cultures that accept the uncertainties are tolerant to different views; attempt to respond as far as possible, are generally more relativistic and enable schools of thought flow freely. The resistance to the uncertainty is related in level of cultural anxiety or neuroses.

Individualism/Collectivism: refers to the degree to which individuals are integrated into groups. In individualistic societies, people dispense little attention to those who are not directly related to your circles. Now in collectivist societies, people are since the creation to maturity, integrated into strong groups, often to extended families. In summary, measures how people turn and engage in groups, how they look after themselves first instead of the collective;

Masculinity/Femininity: is the distribution of emotional roles between the sexes, this is a fundamental issue for any society. Masculinity is related to competition, positioning affirmative. Femininity approaches to a modest and thoughtful behavior toward others. Another factor that distinguishes cultures with features “masculine” and “feminine” is the level of difference or distance between people by sexual gender. Societies where there are underlying differences are considered as “masculine”, the reverse is considered “feminine”.

Long-Term Orientation: is the acceptance of the legitimacy of hierarchy, the evaluation of perseverance, without emphasizing itself and based on tradition and social obligations. It is based in the teachings of Confucius and has a profound influence for most Asian countries. Confucian values are based on the persistence with slow results, in the adaptation of traditions to a modern context, in the acceptance of unequal relations, in concern with virtue. These features make Asians become different in terms of management and labor.

The Hofstede's research is the largest case study reported so far, and through a quantitative approach interviewed over a hundred thousand people. The cultural dimensions established by him show that even organizations establishes cultural standards with strict guidelines, these will tend to dissipate, in varying degrees, depending on the different locations that will make their operations.

4 Conclusion

Culture is a crucial issue for the success of organizations in a globalized world. Managers must be prepared to deal with cultural diversity, since this can lead an organization to success or failure. We realize that investments in training and languages will be increasingly needed by companies, it is a matter of competitive strategy and market survival.

The organizational culture represents the system of behavior, norms and social values accepted and shared by all members of a particular organization and that somehow makes it unique. Thus, it is clear that there are many cultures as different individuals.

The companies, in their great majority, depend on its human capital to create, innovate and differentiate them in relation to the market, so it's essential to investment in human resources policies, in order to qualify and motivate your employees and identify variations of climate and organizational culture. Currently there are various methods and instruments with quality validated.

The knowledge management in organizations is still a challenge, however, initiatives such as the creation of corporate universities already established in several companies. The purpose of the corporate university is to provide technical courses for the employees of a specific corporation. Therefore, it customizes the courses in exact accordance with the policies and strategies of companies, reduces training costs and gains speed in conventional training of manpower.

Finally, it is concluded that the theme of 'social culture' still possessed a theoretical scarce, since we used the main platforms for academic research in search of bibliographic material in this article and modest information's was found. Thus, it is expected that this paper will contribute to the enrichment of the subject.

Abstract: This paper presents in-store customer behavioral model gathered from RFID (Radio Frequency Identification) tags communication data. Although this kind of research has been made by various methods such as interviewing or tracking behind customers, Conventional research methods are made by with the existence of customer tracking research, so far. For collection of natural customer behavior, we made a customer in-store behavior research with RFID tags in a real retail store. In a conventional store design theory, it has been thought that increasing the length of staying time can raise the amount of money per person. Therefore, the store has been designed in the form that goes inside of a shop around. The experimental results suggest that there is a correlation between the spent of time and the length of customer walking path.

Key words: Shopping Path; Customer Behaviors; Point of Sales (POS) data; Radio Frequency Identification (RFID); Retail Store; Services Sciences and Management and Engineering

1 Introduction

In Japan, deflation overlaps with a long-term slump in consumer money spends and the regulatory policies for the retail businesses have occurred in the competitive market. Some leading companies utilizing the benefits of business scale fierce price competition to the mid and small companies and make engaging in price competition among the market area. Price competition is a capital oriented method, and it is necessary to compete for the small and medium-sized retail store in another way with the major ones. Therefore, it becomes important for efficient store management to do following activities; Research of customers' Purchase items to prevent from both of the stock out and the surplus of the items and arrange the layout that customers easily find and buy. Service management of retail business in a super-market requires investigations for store operations including the shop layout, sales promotion, and control of customer flows. So far, such investigations have cost very much to examine in real situations. In this study, we propose a handy method for gathering customer walking paths with the RFID tag, and it reports on the result of the experiment in the retail supermarket. We carry out a data gathering experiment for the purpose of the customer-walking path in the store through the RFID tags. The rest of the paper is organized as follows: Section 2 discusses the background of the research and related work; Section 3 briefly explains the field study of the target supermarket; Section 4 describes the basic principles presents experimental results; and Section 5 gives some concluding remarks and future work.

2 Backgrounds and Related Work

A retail store performs many sales promotions in order to make sales increase. One of the conventional methods of the evaluation is with ID (Identification)-POS (Point Of Sales) data analysis^[1]. There have been many researches concerning to consumer behaviors and their decision analysis systems in marketing science literature^{[2],[3]}. They are both based on statistical analysis of Purchasing items and attributes of consumers. On the other hand, several data mining techniques have been used for the analysis^{[4],[5]}. They have been also utilized customers' movement data in a real shop using technologies of RFID (Radio Frequency Identification) tags and video camera tracking^{[6]-[9]}.

In our country, in addition to competing intensification by the regulation, the declining birth rate and the growing proportion of elderly people is advancing at the speed at which the example is not seen in the history. The competition in the domestic market intensifies more along with this population decrease. The method of sales promotion that uses the Reward Card is in common in the Japanese retail business. For instance, it aims to enclose the customers and gathering customers excluding price

attractiveness to double the point of a Reward Card to Purchase more items as usual. Moreover, the store layout has been regularly changed for the sales promotion. So far, the layout change had been understood to affect customers' flow in the store in the rule of thumb up to now. Therefore, the most efficient method of understanding the customers' flow in the store is required.

We are conducting a research project to develop a decision support system to increase the service productivity on retail store management including ordinary super markets ^{[10]-[14]}. In the current situation, however, to measure the individual customers' behaviors in real time is very difficult because of the measurement costs and decision algorithms of customer behavior. This is a part of the research report.

3 Experimental Setup in the Target Store

This section explains the setups and results of field study with RFID tags in the target store. The condition of target store and setups of field study is shown in Table 1.

RFID is one of the individual recognition technologies using a radio antenna and an IC tag. This device is mainly used for logistics inventory so far, and an indoor location estimation method is focused with RFID, recently ^{[15], [16]}. Since RFID is comparatively small, its influence that it has on a customer is small under the research. Figure 1. indicates the RFID antenna location and layout of the store, Figure 2(a). indicates the RFID tag position attached a shopping cart, and Figure 2(b). indicates the RFID tags mounted on a fixture, respectively.

Table 1 Condition of Target Store and Setups of Field Study

Store Location	Shimane Prefecture, Japan
Operating Hour	9:00 – 21:00
Daily Average of Customers	2,000
Experimental Period	March 3 – March 5, 2011
RFID Antennas	10 on display fixture, 6 on each register
RFID Tags	53 on shopping cart(Half of shopping cart)

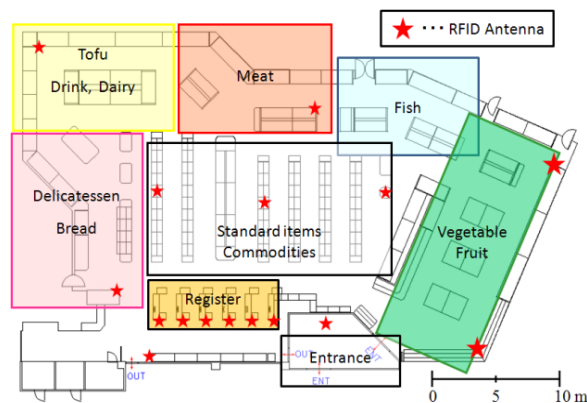

Figure 1 Store Layout and RFID Antennas Position

Figure 2(a) RFID set on a Shopping Cart

Figure 2(b) RFID set on a Display Fixture

As for the shopping path, we assume the shopping path from the entrance to the register. We consider the path as an edge and the fork as a node to estimate the customer shopping pass. Figure 3 indicates nodes and edges in the target store. Since we can trace the position of fixture from POS data, we assume that the customer passed through the path in front of the fixture of Purchase items.

As for the staying time, we assume the staying time as between from the time received radio wave from the antenna tags in the vegetable section to the time received the radio waves in the cash register.

If we synchronize POS data with RFID tag set on a shopping cart or a shopping cage, we can estimate both the staying time and the position of passed fixture for shopping path calculation. Figure 4. indicates the communication range of antenna. The communication ranges of RFID tag set on fixture indicate surrounded by blue respectively. From the preliminary experimental results of RFID communication range, it is determined whether passed through the path in which signal strength and antenna tag number of the communication destination.

Figure 3 Nodes and Edges in the Target Store

Figure 4 Communication Range of the Antennas

4 Analytical Results from Gathering Data

The shopping paths from POS data and RFID communication data with fifty transactions issued on March 4, 2011 are analyzed. Table 2. indicates the result of the statistical results. Table 3. indicates the relation of shopping path, staying time, number of Purchase items, Purchase volume. As for the shopping path, it turned out to be less relation with number of Purchase items or Purchase volume.

Table 2 Results of Gathering Data

	Walking Path (m)	Staying Time	Number of Items
Average	174.07	14':45"	12.38
Std Dev.	83.28	11':06"	8.04
Median	157.44	10':26"	10.00
Min.	42.55	03':44"	2.00
Max	425.11	47':51"	39.00

Table 3 Relation of Gathering Data

Elements	Correlation
Shopping Path – Staying Time	0.8284
Shopping Path – Number of Purchase Items	0.4341
Staying Time – Number of Purchase Items	0.2598
Number of Purchase Items – Purchase Volume	0.8921
Shopping Path – Purchase Volume	0.4346
Staying Time –Purchase Volume	0.2894

Figure 5 Histogram of Staying Time (Method: Sturges)

Figure 6 Histogram of Shopping Path (Method: Sturges)

Figure 5. indicates histogram of staying time. The horizontal axis in figure 5 shows staying time with 5 minutes interval. Figure 6. indicates histogram of shopping path. The horizontal axis in figure 6 shows shopping path with 50 meters interval.

Figure 7 Staying Time and Number of Purchase Items

Figure 8 Shopping Path and Number of Purchase Items

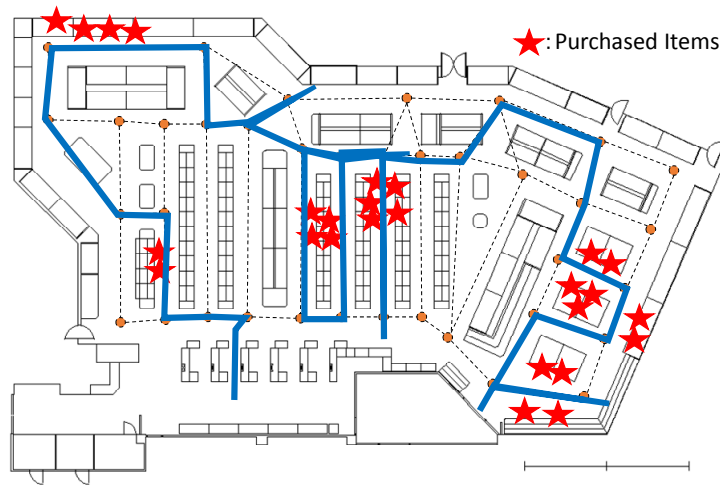

Figure 9 Example of Short Shopping Path with Large Purchase Items

Figure 7. indicates the relation of staying time and number of purchase items. Figure 8. also indicates the relation of shopping path and number of purchase items, respectively. From the analysis, the staying time extends, the shopping path get longer. Even if the shopping path or staying time gets longer, the number of Purchase items does not increase.

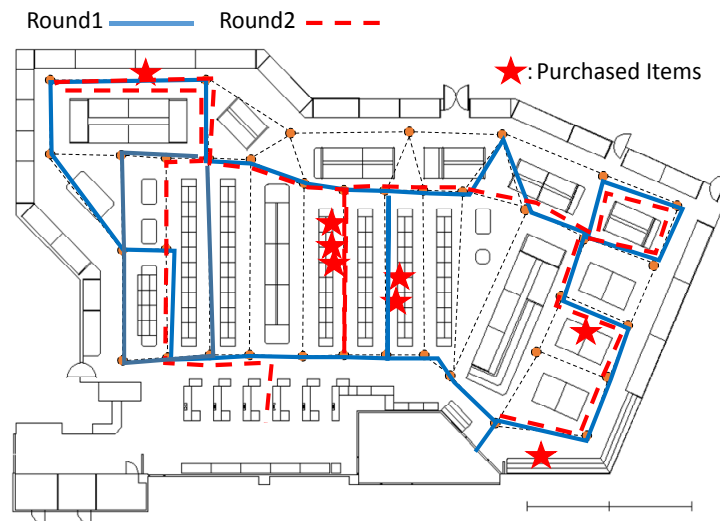

Figure 10 Example of Long Shopping Path with Small Purchase Items

Figure 9. indicates example of short shopping path with large purchase items. This customer took items with same category intensively and might be seen well understand the item position in the store for shopping around efficiently. Figure 10. indicates example of long shopping path with small purchase items, respectively. The blue line shows first round in the store and the dot line in red shows second round in the store, respectively. This customer made two rounds in the store and went back and force in the same place. It is impossible to figure out which round might be put in the basket from this result. According to the real observation in the target store, Most of the customers look around in the store in the first round for the preliminary research and take target items in the second round.

5 Concluding Remarks and Future Work

This paper has presented investigating for analyzing customer shopping path in a supermarket which aims at developing a marketing decision support system for retail management. We have described the research background, research setup, and experimental results of field study. Before executing studies, we have carried out intensive field survey and POS data analysis to uncover the current situations of the targeted super-market. The experimental results have suggested that the staying time in the store extends, the shopping path get longer. And even if the shopping path or staying time gets longer, the number of purchase items does not increase. Our future work includes 1) analysis regarding customer information base on a reward card and product categories, 2) analysis of customers' branching probability in a real store to ground walking flow, 3), and 4) mounting the results of customer behavior data with the simulation. These work will require practical experiments and further survey studies. We wish to express our gratitude of the cooperation to our experiment.

Research on Real Estate Regulation Measures under the Supply and Demand Models

Yu Yao

School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070

(E-mail: 834510930@qq.com.)

Abstract: With the continuous improvement of the level of economic development in China, the scale of the real estate industry shows the trend that continues to expand. However, due to various reasons, the real estate industry is gradually emerging in the sustained and rapid development, while the supply and demand imbalance, prices have skyrocketed, and other issues, causing a hazard to the healthy development of China's economy. In order to control the real estate industry, the state implemented a number of macro-control measures, but ineffective in recent years. This article will use the supply - demand model elaborated the real estate supply and demand changes under the Under the Government macro-control measures. Through analyzes, Government should take tax to buyers, imply the price ceiling and construct a number of affordable housing and other measures, those can effectively regulate the current situation of imbalance of supply and demand in the real estate market.

Keyword: Real estate; Supply and demand; Tax; Price ceiling

1 Introduction

The real estate industry is an important force to drive economic development in our current society, real estate supply determines the trend of real estate prices continue to rise. In particular, real estate prices rapidly rising in most cities in recent years. In order to maintain normal real estate development environment, the state has introduced macro-control policies, but not achieve the desired results. Due to various reasons, prices rise continuously. Implying effective real estate tax system not only can coordinate the operation of the national economy, but also increase the national income. In this paper, the demand - supply model is used to study the condition of the real estate market, Analyze respectively market conditions, real estate market demand, supply and balanced relationship in a perfectly competitive. At the same time, we analyses that supply demand and price changes under the condition that the government take demand-side tax and imply price ceiling. It can be draw that if the Government take demand-side tax and provide affordable housing, the contradiction between supply and demand of the real estate market can effectively easy.

2 The Supply-Demand Situation of Real Estate Market in China

Judging from the development trend of supply and demand, demand will be influenced by high price in short term. The possibility of house prices falling down is very small in long term. As mentioned earlier, the demand of real estate market can be sorted into life demand, improving demand, investment demand and speculative demand. Both life demand and improving demand are rigid, their change is also a pattern. Under the new situation of Macro-control, some consumers expect house prices to fall, and maybe wait for housing price further going up.^[1] But in long term, this part of demand is an objective reality and it's quantity is very huge, those demand is also bound to be released. To demand for investment and speculative, under the macro-control policies, investors will be more rationally analyze investment income, this part of demand will significant decline in the short term. But view from long-term, when interest rate policy and exchange rate policy have not big change, investment channel keeps also single, where to use the withdrawal funds from the property market is still a big problem. If there is no better investment channel, these funds may also return to the property market, which will continue to push up house price in the next wave of market.

Supply situation in short term is difficult to have a big change. In long term, with China's second-hand housing market gradually standardized, the further development of the real estate market and other factors, the housing market in China will increase effective supply.^[2] But the real estate market's supply comes mainly from real estate development. At the premise that the scale of investment in real estate development is still too large and housing prices soar, real estate development and investment further accelerate is unrealistic. Therefore, judging from the trends of supply and demand, the huge shortage of demand and supply of residential housing in recent years will last. Under the regulate of Strict macro-control policies, the growth rate of real estate prices will go down but the rate of

decline will not be too much in the short term. However, real estate prices will show a continued slight rise in long term.^[3]

3 Analyse on the Demand - Supply and Price of Real Estate

3.1 The relationship of supply, demand and price under perfectly compete

Perfectly competitive market structure means there are a large number of enterprises in an industry, the market share of any enterprise is very small, what is more ,they all produce homogeneous product .So, any one of the enterprise lack the ability of control market price. In this case, the point of intersection of the line determines the market price of the product, and the price is called the equilibrium price in economics. Figure 1 shows the situation.

Figure 1 The Relationship of Supply, Demand and Price in Perfectly Competitive Market

As mentioned above, all the points in the demand curve represent the quantity of certain products that consumers are willing to buy at particular price. Each point in the supply curve indicates the quantity of a particular product that the seller is willing to provide at certain price. The point that Supply and demand curves intersect denotes that demand quantity is amount to supply quantity, it also means that the transaction at this price enables both parties Satisfy. In Figure 1, the intersection K of the two curves is equilibrium point, at the same time, the transaction amount Q_0 is called balanced trading volume and the price P_0 is called the equilibrium price. Why it is called “balance”? Because if the price is higher than P_0 and become P_1 ,at this time, the supply quantity is greater than demand quantity($Q_{S1} > Q_{D1}$), so the seller can not find enough buyers, and it will cut the price down. If the price down below the P_0 and is P_2 , when the demand is greater than supply ($Q_{D2} > Q_{S2}$), the buyer can not buy the desired amount of what he wants, and the price would be much too high. So, when the price is not P_0 , there will be a trend that price tend to P_0 ,the price towards the direction of P_0 in the prices until it eventually becomes P_0 , demand and supply are equal, the amount buyers want to buy equal to the seller wants to sell .As long as there is no new factors in the intervention, the price will not change. So, at this time, this market reaches equilibrium.

3.2 The implementation of Price ceiling

Figure 2 The Government Limiting Price Affects Supply and Demand

In the current real estate market, due to the insufficient supply and inflation, the house price have been rising .At this time, the government in order to get the goal that meet the normal housing demand of our people, often take the measures of price ceiling.

As shown in figure 2, assume that under normal market conditions, the supply curve is S, the demand curve is D ,the equilibrium point is K, the balanced price is OH ,and the balanced trading volume is ON, Now Government think balanced pricing is too high, making the maximum price for OI. if the market price exceeds the OI, then it is illegal. From Figure 2, you can see the results of such a requirement. If the price is set at OI, the supply will be reduced to the OR, and the demand will increase to OL, therefore, there will be supply shortage. The shortage number is OL-OR= RL, this part of the shortage requires the Government to provide or carry out the countermeasure of macro-control. Supply shortages may cause a series of bad phenomenon in the real estate market, such as the purchase is difficult, the decline in the quality of the housing. ^[4]Therefore, the Government implying the price ceiling of real estate industry can combat high prices, and can protect the normal interests of the people .However, in order to make up the reduced supply that lead by the price ceiling and satisfy the normal housing needs of people, the government should construct promptly a number of houses or encourage enterprise to build affordable houses by providing subsidy or carrying out tax-free policy.

3.3 Government consumption tax levied on the supply and demand, prices

Under the conditions of market economy, the government consumption tax levied on commercial housing will lead to higher prices, partially offset by decreases. Now assume that the government levies excise taxes on commercial housing, per unit square meter levy a certain amount of tax^[5] Although, this will not affect the taxation on the demand curve. Because the tax is paid by the consumer or real estate business to the country, buy for the price includes taxes does not care; they care about the level of prices. If the price increases, the demand will be reduced; conversely, on the increase. So, no effects of taxation on the demand curve.

However, the tax effect on the supply curve, the market mechanism, the number of commodity supply and demand as well as changes in market equilibrium price depends on many factors. This article only based on the static principle of market supply and demand and the price mechanism analysis. Three tax policy measures on the providers we have taken, namely direct sellers who charge sales tax, personal income tax and VAT on land for real estate development enterprises. Its effect is analyzed theoretically: When the governments increase tax to the seller, this will increase directly the cost of providers. ^[6]In the case of other conditions remain unchanged, in order to obtain the same profit as not be taken tax by the government, the provider will add tax cost to the sale price, which means that buyers will be demand to pay higher prices than before. This lead to the supply curve to the left and form a new market equilibrium point. This led to the supply curve to the left to form a new market equilibrium point: The new market equilibrium in supply and demand, equilibrium price under the assumption that the same demand curve improving the market-clearing reduction in the number.

Figure 3 Government Imposing Taxes Affect the Supply and Demand

Therefore it can be concluded that: The most likely outcome of the effects of taking supply-side tax in the residential real estate will cause house price further improvement, the quantity of residential real estate supply may reduce. As it is Shown in the figure 3: D stands for the demand curve, S1 stands for pre-tax supply curve, and E₁ is the equilibrium point of supply and demand before tax. At this time, the equilibrium price is P₁, and the equilibrium quantity is Q₁.If the government take taxation on the supply side ,then the supply curve will moved to the left S₂ and form a new equilibrium point E₂ of

market supply and demand. In this equilibrium point, the market price will rise from P_1 to P_2 , the quantity of supply will reduce from Q_1 to Q_2 .

As the above figure shows, we can draw the preliminary conclusion that: the effect that the government take the tax policy of real estate to curb price growth is limited and is likely to promote house prices more higher, especially in the situation that supply quantity is less than demand quantity, the effect is more smaller. At the same time, these measures may control the expansion of the scale of residential real estate. In the idea, further improving tax policies achieve the target that the government is able to control the excessive growth of house prices and suppress the scale of real estate expansion. The extrapolation of the theoretical analysis is: If the government take tax on the supply side in a competitive market, the tax burden will be often passed on to the consumer, especially in the situation that the supply quantity is less than the demand quantity, then the transfer is relatively more easy to achieve.^[4] However, if government takes tax on the demand side, it is almost impossible to transfer tax, and house prices will not rise as a result of taking tax on the demand side. What the tax burden increase in demand side may lead to a drop in demand, achieving the goal of Suppress price and demand.

4 Conclusions

Seen from the related analyze of the supply and demand curves, we can draw the conclusion that some of the macroeconomic policies adopted by the government play certain inhibited effect on the price, but not solve the house bubble from the source. Existing contradictions in the prices of supply and demand in China, we should look at several aspects to improve.

4.1 Set reasonable property taxes and increase difficulty of purchase the second suite

Although the supply amount of housing is increasing in China, but many people still do not have a house to live. Part of the reason is that rich people sometimes has several upscale house and idle the houses there, which crowd the poor people living space, these finally cause housing resources waste or can not be effective configured. The government should improve the system of real estate price appraisal, real estate tax assessment policies and property registration. It is especially emphasized that the government should make laws and regulations to strictly crack down on speculation in the real estate market, For example, the government can take the measure that the second suite are not permitted to be bought by down pay and improve the tax levy proportion of the second suite property.

4.2 Transfer taxation objection to improve the costs of holding multiple sets of real estate

In my opinion, We strongly advice that the Government should shift gradually the taxation objection of the real estate from tax on the supply side to tax the demand side tax in the future. Taxation on the demand side means taking tax in the link of holding the real estate. Although China have real estate tax, urban real estate tax, urban land use tax and other taxes at present, but our government take no tax on the part of holding personal residential real estate. Therefore, as long as the person who possesses the real estate make no transfer transaction, this part of real estate is still not bear the tax burden. Therefore, the cost that possess residential real estate so as to save the cost of wealth is still very low. So that the current tax policy will not be able to suppress real estate speculation and can not make a big different in the protection of people normal needs. Taking tax on the holders of real estate taxation, especially taking tax on the holders who have several sets of real estate, can effectively suppress real estate speculation.

4.3 Increase the supply of affordable house through constructing or implying subsidies

Developers are economic man who pursuits of maximized profit, they supply only high-end house, all these lead to the supply of low-profit affordable house reduce, and caused Cheap house vacant. This requires government to take Macro-control measures to improve the situation: To the vacancy market of weak profit in the real estate market, the government can build larger numbers of affordable house, cut tax and provide subsidies, by which increase the supply of affordable house.

4.4 promote the development of small and medium-sized cities

At this stage, the Government has repeatedly limit for housing prices of second-tier cities, but the majority of people still poured into these bustling cities as flood. Because the modernization of major city is high and have many developing opportunities, so people are not willing to stay in small town. Therefore, the government price regulation can Only ease the tension of supply and demand in real estate market in short-term. In order to tackling the problem, we need to speed up the construction of small and medium-sized cities, which can narrow towns gap. This can disperse population pressure and alleviate housing stress in major cities. This is a long-term strategy of balance the supply and demand of

China's housing market.

Abstract: Based on the asymmetric information, the informal finance system is easy to generate the risk conduction effect and has certain hazards. It is necessary to conduct scientific research on it, and propose effective management and control measures. This paper analyzed asymmetric information incentives of informal finance risk conduction from three aspects, including macroscopic reasons, macro reasons and micro reasons. Then studied the informal finance risk conduction effects, such as Domino Effect, Broken Window Effect, Butterfly Effect and Coupling Effect, and put forward the control measures of informal finance risk conduction.

Key words: Asymmetric information; Informal finance; Informal finance risk; Conduction effect

1 Introduction

Informal finance plays a significant role in resolving the financing problems of small and medium enterprises, promoting the development of finance-ecology system and so on. The inside and outside scholars from the research founded that, the cause of informal finance was that it had advantages than Formal Financial Institutions in the aspect of asymmetric information. Hoff and Stiglitz(1994) believed that because the main transaction subjects was always individuals or businesses related by blood or geopolitical relations, the lenders was very understanding of the borrower's private information, such as operating conditions, repayment abilities, credit, moral quality and so on, the almost free information settled for a long time made folk loan have a lower transaction costs, what was the premise of folk loan^[1]. William F. Steel, et al(1997) argued that informal finance took advantage of the local private information so as to have a comparative advantage in solving asymmetric information, this was the important reason informal finance generated^[2]. In our country, with the rapid development of informal finance, informal finance has no longer limited to the single mode which is established between relatives and friends, but cross the existing orbit to do credit behaviors through the cross-people, cross-region, or intermediary agent, the problems caused by asymmetric information is highlighted. Zhou Hongyan, Zeng Liping and Li Wenzheng(2008) described the four new characteristics of informal finance risks, one of which was that with the informal finance scope became larger, asymmetric information would lead to institutional risk^[3]. Ma Hongman (2011) analyzed the hidden danger existing in informal finance as the example of Wenzhou city informal finance events, and warned people to beware of the domino effect of informal finance risk^[4]. Therefore, with the rapid development of informal finance, it presents the characteristics of diversification of involved subjects, complexity of business types, asymmetric information between suppliers and demanders and so on. In particular, under the real financial management environment of poor supervision, legal bug, and lacking of credit, informal finance risk conduction effect caused by information asymmetry is increasing day by day. It is necessary to study the related problems of informal finance risk conduction effect under asymmetric Information.

2 Asymmetric Information Incentives of Informal Finance Risk Conduction

According to the different levels, the incentives of asymmetric information in informal finance risk conduction could be classified into three categories: macroscopic reasons, macro reasons and micro reasons (as shown in figure 1). Macroscopic reasons mainly refer to the factors which exist beyond the scope of informal finance system so as to cause asymmetric information of the informal finance risk conduction, such as national policies factors, national laws and regulations factors, social culture factors, economic environment factors and so on. Macro reasons mainly mean the factors of asymmetric information of informal finance risk conduction caused by the informal finance operating environment condition and the system of itself, such as informal finance industry management system, business regulation, pricing model and so on. Micro reasons mainly come from the direct interest subjects in

* This paper is supported by "the Fundamental Research Funds for the Central Universities" (2012-IB-070).

informal finance, such as capital demanders, intermediaries and capital suppliers. In all the reasons, the macro reasons are easier to lead to the informal finance risk conduction directly.

Microscopic reasons are also known as internal reasons, namely the direct factors cause asymmetric information of informal finance risk conduction. However, the macro and medium levels are collectively referred to external reasons, they are the indirect factors which like catalyst in chemical reactions and promote the asymmetric information of informal finance risk conduction to occur. As in the external environment of the economic and social development, informal finance has no longer limited to the loan modes between relatives and friends, but loan relations from high information transparency to low information transparency. It has formed loan modes through the cross-people, cross-region, or intermediary agent. In order to obtain the capital suppliers' fund, some disqualified capital demanders try to make every attempt to find loophole in informal finance system (simple operation, no project risk assessments, etc.) by fabricating false information, to obtain the capital supplier's trust, all of which finally lead to serious information asymmetries, and result in occurrence and transmission of adverse selection and moral hazard in informal finance. Meanwhile, under the lack of the laws and regulations protection, some legal-loophole-seeker informal finance intermediaries use every possible means to keep their own interests. They use high interest rates as bait to cheat public funds. All of which disrupt the normal development of the financial industry and the social stability seriously.

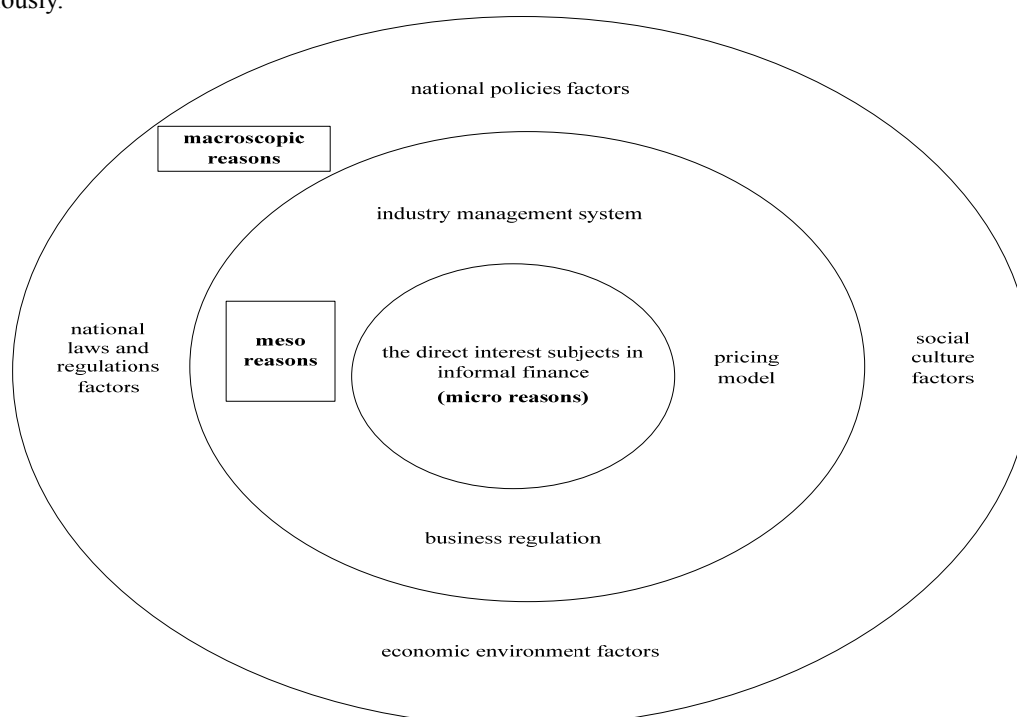

Figure 1 Asymmetric Information Incentives of Informal Finance Risk Conduction

3 Informal Finance Risk Conduction Effect

3.1 Domino Effect of Informal Finance Risk Conduction

Heinrich found that the happening of the risk had the characteristics of dominoes from the study, once there was a problem happened in a small link of the interconnected system, it would cause a chain reaction. Take the informal finance incidents happened in recent years for example, under asymmetric information, the cases about domino effect of informal finance risk conduction are too numerous to be mentioned. For example, since 2009 the “fund chain” in Wenzhou in Zhejiang province and Ordos in Inner Mongolia had been broken, which led to some bosses run away or committed suicide. Because the simplicity of operation process in folk loan provides convenience for the small and medium enterprises to raise funds. In order to get high interest, the capital suppliers invest their funds for these small and medium enterprises or personal under the huge false temptation. Eventually, because the market is recession, these small and medium enterprises hardly afford the high rates of folk loan, and then the risk happen, which conduct the risk to all of capital demanders and other enterprises, making capital

demanders suffer huge losses, all of which form the domino effect of informal finance risk conduction(as shown in figure 2).

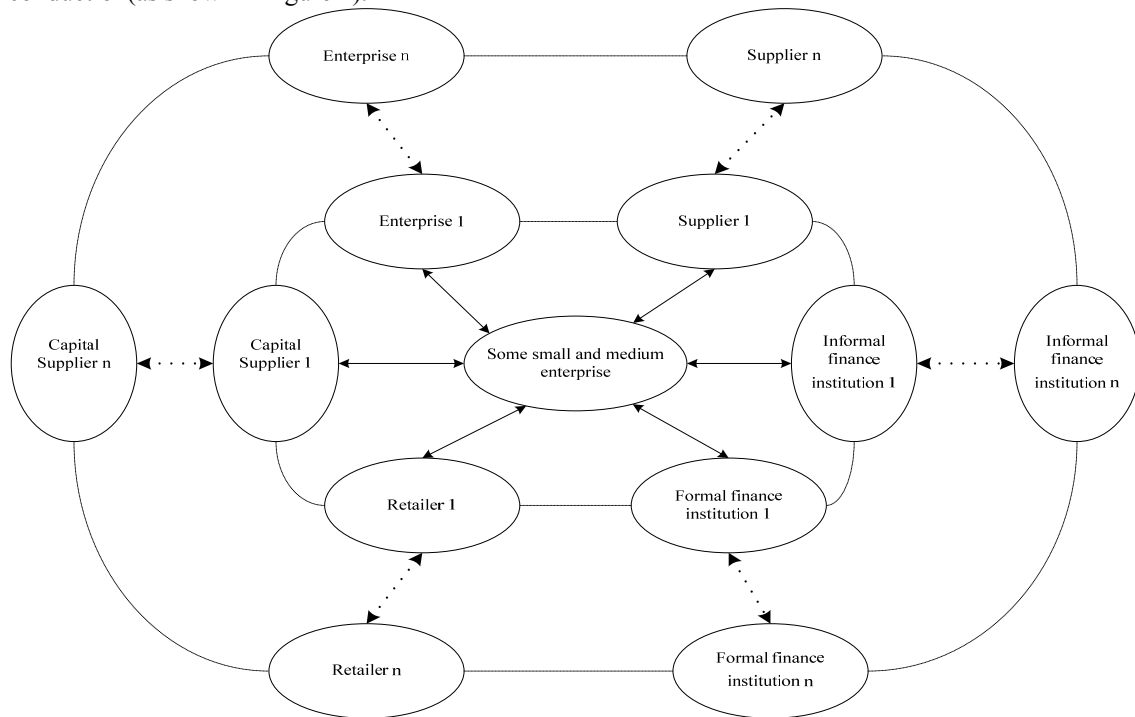

Figure 2 Domino Effect of Informal Finance Risk Conduction

3.2 Broken Window Effect of Informal Finance Risk Conduction

The broken window theory believed that considering a building with a few broken windows, if the window are not repaired, the tendency is for vandals to break a few more windows, eventually, they may even break into the building, and if it's not unoccupied. This effect also exists in informal finance risk. Under asymmetric information, capital suppliers of informal finance have no effective and strict economic evaluation for capital demanders, and have weak consciousness of risk control and prevention. In order to pursuit the high-risk benefits, they blindly lend funds to capital demanders in the poor credit conditions, especially to the small and medium enterprises. When one of the capital demanders can't stand high interest debt so as to give up repayment, and lenders don't contain this kind of behavior in time, it will give other capital demanders a psychological suggestion. Finally, everybody will imitate the "broken window" behavior, deliberately not be eager to pay off debt, finally it makes more bad debts to the capital suppliers, resulting in serious losses. As the event of Wenzhou enterprises shareholders collective evaporation happened in recent years, since the capital demanders can't be able to repay high interest of informal finance, few small and medium enterprises bosses "run road", which caused much more bosses hidden themselves to evade payment of debt.

3.3 Butterfly Effect of Informal Finance Risk Conduction

The father of Chaos theory--Edward Lorenz believed that a slight variation in the initial conditions could lead to the long huge chain reaction in the whole system. For example, a butterfly fluttering occasionally can cause a tornado. This effect also exists in the informal finance risk conduction. Under asymmetric information, any small link in the informal finance system goes out of control, if it dose not timely be controlled or guided, it will cause a serious of adverse reaction in the retire informal finance network. For example, when the country implements tight monetary policies, tightening bank and estate policies, finance institutions limit for small and medium enterprises' credit support strictly, the borrowers will choose the informal finance institutions to raise funds. Under asymmetric information, some social capital flow into those enterprises or personal which have poor performance and low qualification naturally. This not only hinders the stable and healthy development of social economy, but also disturbs the normal financial order.

3.4 Coupling Effect of Informal Finance Risk Conduction

Coupling refers to the phenomenon that two or more system or two motion forms combine by

influencing each other^[5]. Coupling effect is a phenomenon that two or more systems through the intermediate link between correlation and mutual relationship, under the way of action and reaction, attract and repel each other and then form larger effect .

Under the informal finance risk conduction process of information asymmetry, the stakeholders or every link of operation have directly or indirectly relationship with each other in the informal finance loan relation. By the influence of reaction, the nature and intensity of informal finance risk may be changed in the conduction process of reaction. According to whether the intensity of informal finance risk conduction changed, the coupling effect of informal finance risk conduction is divided into pure coupling effect, weak coupling effect and strong coupling effect. If the effect of informal finance risk conduction is $1+1=2$, it is pure coupling effect. For example, under asymmetric information, the flow rate and intensity of formal finance risk do not change greatly, which will fluctuate in a small range. If the effect of informal finance risk conduction is $1+1>2$, it is strong coupling effect. Such as asymmetric information, capital suppliers lend money through intermediaries to different capital demanders (such as small and medium enterprises) in the pursuit of huge interest. The risk effect of flow rate and intensity of informal finance risk can be enlarged under the influence of internal and external factors through multiple paths. If the effect of informal finance risk conduction is $1+1<2$, it is weak coupling effect. Under asymmetric information, capital suppliers can select the capital demanders strictly and make risk prevention, the risk effect of flow rate and intensity of informal finance risk will gradually diminish or disappear in the conduction process.

4 Control Measures of Informal Finance Risk Conduction under Asymmetric Information

4.1 Control Measures of Informal Finance Stakeholders

4.1.1 Capital suppliers

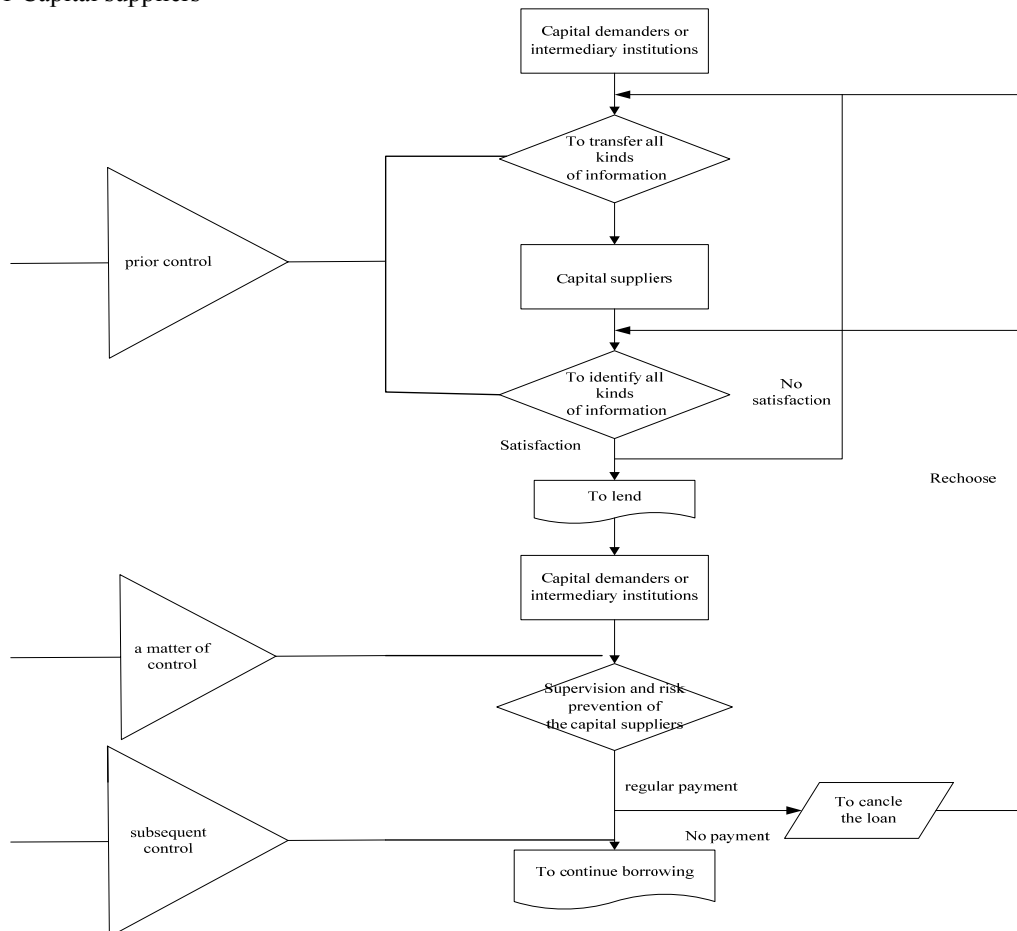

Figure 3 Informal Finance Risk Conduction Control Model for Capital Suppliers

In the informal finance loans behavior, the capital suppliers belong to information disadvantage. In the informal finance risk conduction control, the capital suppliers should take the effective measures to truncate the risk transmission path before and after lending, to prevent transmission of risk (as shown in figure 3). Capital suppliers could choose the ideal borrowers according to the signals from capital demanders or intermediary institutions before the loans happen. Firstly, the suppliers can make a preliminary investigation to the capital demanders and intermediary institutions, and be fully prepared to choose the appropriate borrowing candidates or institutions. Besides, distinguish the information of alternative borrowers and intermediary institutions, and let borrowers or institutions make a loan guarantee if possible. Finally, choose the appropriate borrowers or institutions. At the same time, they should track and focus on the important information of borrowers and intermediary institutions regularly, taking follow-up effective measures prevent bad loans. By a series of effective control measures before and after loan, it is possible to reduce or block the risk conduction effect in informal finance.

4.1.2 Capital demanders

Under asymmetric information, compared with informal intermediary institutions, capital demanders are in the advantage of information, some intermediary institutions will use the attitude that capital demanders are eager to raise money but can't get from formal finance institutions to raise the loan rates. It makes capital demanders suffer serious losses eventually. Therefore, in order to prevent the risk transmission, capital demanders should make an effectively investigation and understanding to the capital suppliers and intermediary institutions, especially to the intermediary institutions, such as whether the agencies have formal business license, or are consist with the pricing of intermediary institutions in the market before borrowing money. Only in fully understanding of capital suppliers or intermediary institutions can they raise money. Meanwhile, effective risk prevention measures after the event can reduce the high rate and fraud risk. Through a series of measures, the informal finance risk conduction effect under asymmetric information could be control.

4.2 Control Measures of Informal Finance Supervision

4.2.1 Accurate the law construction of informal finance

Under asymmetric information, the external reasons of informal finance risk conduction effect are lack of legal protection and have supervision gaps. Therefore, the States as the informal finance supervision should enact laws to protect the informal finance stakeholders, making informal finance become legal and establish a legal platform of folk loan. Firstly, establish lending standards according to own actual situations for capital suppliers or intermediary institutions, and register in relevant department. Secondly, after the registration, capital suppliers or intermediary institutions should be qualified license according to the relevant materials they provided, then they can implement loan. Thirdly, draw up a set of folk loan process procedures, and regulate the money-lending business, improve the link and process of folk finance loan transaction. Such as capital suppliers can implement rational and scientific evaluation in advance before the transaction, including the basic situation of the capital demanders, the purpose of the money, interest rate and whether contracts are normal, or they have the risk of collateral or not, their mode of payment and payback period. Fourthly, the funds should be classified, and strictly stop the use of funds which conflict with national policies or laws and regulations. Fifthly, set corresponding interest rates range according to capital uses and limits, to prevent capital demanders' foreclosure because of high interest rates. Sixthly, standardize capital suppliers or intermediary institutions and make clear rules for them, which can protect the legitimate and reasonable capital suppliers or intermediaries, combat criminal individual and institutions activities by using the folk finance loan. Lastly, supervise capital demanders' behavior strictly, prevent them from cheating capital suppliers or institutions.

4.2.2 Strengthen the supervision and management of the informal finance

The informal finance activities have the characteristic of wide range and strong degree of freedom, if you don't take charge of it, the risk conduction effect triggered by low degree of information will happen from time to time. Therefore, in order to control the risk conduction in informal finance under asymmetric information, it is necessary to carry out effective supervision management for informal finance loan, and establish the corresponding risk prevention measures. Firstly, the state should set up the specialized informal finance supervision departments, record and track the loaning information, update it regularly, stop the source risk timely, all of which can prevent the risk transmission. Secondly, encourage all capital demanders to register loan information in supervision departments actively; the large amount of credit should be consulted about the risk prevention measures in the departments, in order to guarantee the safety of the funds. At the same time, we should set up a cross-country informal financial supervision network, establish a unified informal financial supervision network system, control

a serious of processes and punish the illegal procedures strictly.

5 Conclusion

Under asymmetric information, informal finance risk conduction effect happen from time to time, analysis on the domino effect, broken window effect, butterfly effect and coupling effect generated by informal finance is a new topic, and has a certain practical significance on the informal finance management. This paper analyzed asymmetric information incentives of informal finance risk conduction from three aspects. Then studied the informal finance risk conduction effect in depth and put forward the control measures of informal finance risk conduction. This paper studied the informal finance risk conduction effect in theory, the next research direction will be to collect relevant data and prove the correctness the above theory from the quantitative aspects.

Evaluation of Public Satisfaction Towards Governmental Public Sectors Based on SEM

Gong Kelan, Liu Guolong

School of Arts & Law, Wuhan University of Technology, Wuhan, P.R.China,430070

(E-mail: 5552544@qq.com, 510993667@qq.com)

Abstract: With the deeply development of government performance evaluation, the research of evaluation of public satisfaction towards governmental public sectors draws more and more attention. By using structural equation modeling, this paper investigates the factors which affect public satisfaction and the relationship between them. The research results show that: public expectations directly influence public satisfaction, and through the mediating variables, public satisfaction, public expectations indirectly affect the behavior of the public. Meantime, public expectation will affect public satisfaction through the mediating variables, perceived value, ultimately affecting public behavior and proposing the management mode of governmental public sectors, in order to improve public satisfaction.

Key words: Governmental public sectors; SEM; Public satisfaction; Factor analysis

1 Introduction

Government performance evaluation is the result which is jointly promoted by the development of western society, new public management and public administration theoretical research. As the government is regarded as an agency that provides public goods or services entrusted by the public, the subjective criteria of performance evaluation is to check whether the public is satisfied or not. Therefore, when evaluating government performance, we should not only inspect how many costs and resources the government has put in and how much work is been done, but also investigate how large the extent that all it has done can meet the needs of society and the public, and receive public recognitions. Only has the government gets public recognition and satisfaction, its behavior can be considered to be the most performing. Based on this concept, since the 1970s, the value orientation of western governments' performance evaluation has gradually shifted from the pursuit of economy, efficiency and effectiveness to the pursuit of the quality of public goods or services provided by the government and the citizen's satisfaction (Qi, 2011). This paper takes public satisfaction as the starting point, to build the causal relationship mode of public satisfaction and do empirical research, putting forward the corresponding countermeasures and suggestions.

After a review of literature from home and abroad, the author finds that the related research of the evaluation of public satisfaction towards governmental public sectors at abroad is more mature. Welch (2005) studies the relationship between government information construction and public satisfaction, pointing out that the transparency and interaction of government information construction are the important factors which have an impact on public satisfaction. From the perspective of the public, Hao (2013) holds the view that the improvement of public satisfaction is the important method and vector of government management, and an open, transparent, efficient and information sharing government management mode needs to be built. In order to improve public satisfactions, Hsu thinks that we should effectively enable and expand the construction of public sector information technology and improve the efficiency of government public sectors and people's satisfaction towards the government through social influence and perceived performance. Because of the successful use of customer satisfactions in the enterprises, since 2000, domestic scholars began to use the satisfaction in government departments, and conduct extensive related researches, obtaining a wealth of research results. Zeng (2006) considers that evaluating government performance by regarding public satisfaction as the orientation is the inevitable requirements to build a modern and efficient government. In our country, because the assessment model is oriented to public satisfaction, the content, subject, objectives and principles of the performance evaluation of the government public sectors will suffer the obstructions from awareness, institution and technology in reality. In regard to the difficulty of public satisfaction of the government's public services, Liu (2008) uses the fuzzy multiple attribute decision making method which is based on the expectations and the interval evaluation matrix combining quantitative indicators with qualitative indicators to measure public satisfaction of the government public services, providing a more scientific and feasible mode for quantitatively evaluating public satisfaction of the government public services. Xin (2008) builds a government evaluation index system

based on the public from five aspects which are information disclosure, online work, public participation, website design and customer awareness. And she evaluates the government website performance from the perspective of public satisfaction by using F integral comprehensive evaluation model. Taking public satisfaction of Shenzhen municipal government information opening as the evaluating object, Duan (2010) collects information about public satisfaction, obtains various structural correlation coefficients between the variables and overall satisfaction towards government information opening of the public in the mode of public satisfaction of Shenzhen municipal government and its departments' information disclosure, and he puts forward the corresponding countermeasures. Through the literature from home and abroad, we can find that most of the present studies are descriptive researches but lack of targeted researches, and there are few empirical studies of the relationship between the factors which will influence public satisfaction. Even though Jiang (2009) studies the relationship between public satisfaction and public behavior, his research is only from the perspective of public psychology, starts to study the behavior intention from negative emotions, and does not contain the study of specific public expectations, perception and the public perceived value. This study adopts the Structural Equation Model, conducting empirical analysis of the relationship between the factors of public satisfaction. What's more, from the relevant theory, this research has designed questionnaire survey and builds the structural equation modeling between the public satisfaction factors.

2 Data Collection

First of all, in order to guarantee the reliability of the questionnaire, the author conducts interviews with the relevant people to determine the main part and specific questions of the questionnaire. Subsequently the questionnaires are distributed to the experts in the related field. The experts are expected to propose amendments, then the author modifies and improves the questionnaire according to the feedback information. Second, the author conducts the pre-test questionnaire survey in a small-scale, to carry out work to further amend and improve the questionnaire. At last, the relationship scale of the relation between public satisfaction and behavioral intention is generated. The entire scale is divided into five subscales which are respectively named service expectations (4 questions items), service aware (5 questions items), perceived value (5 questions items), public satisfaction (5 questions items) and public behavior (3 questions items), total including 22 questions items. The questionnaire adopts Likert's standard five-point scale which shows that 1 for very dissatisfied, 2 for not very satisfied, 3 for ordinary, 4 for quite satisfied and 5 for very satisfied. Questionnaires are distributed to those objects who are government staffs and people who keep close contacting with government staffs. The questionnaires mainly focuses on government staffs, business executives, small private businessmen and so on. There are total 220 questionnaires being distributed, of which 183 questionnaires are validly collected, and the effective rate is 83.18%. From the gender of the research objects, it can be seen that the proportion is basically in 1:1. The objects' qualifications are in tertiary education level and above, and they are around the age of 40 years old. Overall, the samples of the survey are broad and representative, and the research results have strong reliability and persuasiveness.

3 Empirical Analysis

3.1 Exploratory factor analysis

Before analyzing the questionnaire survey data, we must first carry out the testing of reliability and validity of the scale. We can use SPSS16.0 for testing the reliability of the scale. The analysis of the entire scale's reliability shows that, the Cronbach's α value is 0.806, indicating that the scale has high reliability. The Cronbach's α values of subscales' are respectively that perceived value is 0.835, public behavior is 0.793, service awareness is 0.751, public satisfaction is 0.938, and service expectations is 0.829 which all meet the requirements of being greater than 0.70. What's more, the correlation coefficient of all the questions and potential variables is relatively high. Therefore, the scale has higher consistency and reliability. Because of the good reliability of measuring the latent variables, exploratory factor analysis needs to be further expanded. Exploratory factor analysis is aimed to identify the main factors affecting the number of observed variables as well as the relevance degree of each factor and each observed variable (Zhu, 2011). By using SPSS16.0, the author analyzes all the 15 factors. Through the statistical results, we can see that the value of KMO is 0.844 and the test of Bartlett's sphericity value is 1573 which reaches the highest point, indicating that there are common factors existing between the correlation matrix and it is suitable for us to conduct factor analysis. The author uses the maximum likelihood method as the factor extraction method, chooses the varimax rotation method to obtain a

clearer factor solution, and adopts the maximum variance orthogonal rotation. After rotation, the load intercept point of the factor is 0.5. The author removes the question items whose load on any factor is lower than 0.5 or whose load on multiple factors is more than 0.5. After analyzing the iterative rounds of principal component factor, the author finds that there are 5 eigenvalues that are greater than 1, and the cumulative contribution rate reaches 85.46%. The analysis shows that the remaining 15 variables can use these five common factors (respectively are the common factors of public perceived value, the common factors of public behavioral intention, the common factors of public service awareness, the common factors of public satisfaction and the common factors of public expectations) to explain, and the structural design between the variables of the questionnaire is reasonable.

3.2 Model hypothesis

After using the exploratory factor analysis to identify the factors, the author establishes the structural equation modeling, conducts confirmatory factor analysis and path analysis towards equation model, to obtain the equational analysis of model, validity, goodness of fit index and other indexes. When undergoing the structural model fit, the author takes the sample which is less than 500 into account. Because of the use of the method of generalized least squares (GLS) to estimate will obtain better results (Wu, 2009), the author selects GLS method to estimate and uses AMOS7.0 to conduct model parameter fitting towards hypothetical model. The results show that in the eight model fit indices, $\chi^2/\text{freedom}$ index is more than the standard (<3), SRMR index is slightly higher than the standard value (<0.05), RMSEA is greater than 0.05, and GFI is less than 0.9, indicating that the fitting of the model and observational data are in the general level, and the further model optimization and correction are needed. In order to get a better model, it is necessary for the initial model to be amended. What's more, the author finds that the public perceived value's influence to public behavioral intention is not very notable, so its path needs to be deleted. Considering that public expectations may affect the perceived value of public's expectations, the author, therefore, increases the paths from public expectations to perceived value. Furthermore, through the actual operation, the author finds that chi-square value is reduced a lot, and each fit index has also been improved, but there is still a gap between the current fit index and the ideal fit index. Further amending the model through modified index, in Amos, the author uses the maximum likelihood to estimate the running model's parameter estimates. The results are presented in Table 1 and the modified model is displayed in Figure 1.

Table 1 Revised Model Fitting Indicator Parameters

Indicator	chi-square	df	chi-square /df	GFI	AGFI	SRMR	RMSEA	CFI
Result	100.179	78	1.28	0.944	0.914	0.042	0.036	0.935

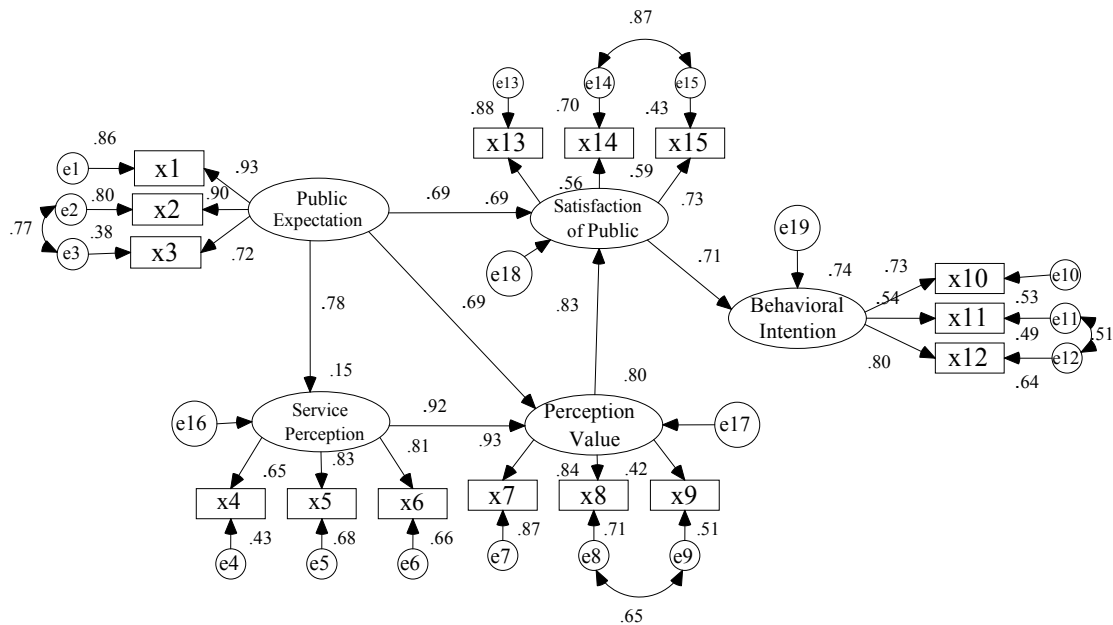

Figure 1 Modified Route Map of Public Satisfaction Structural Equation Modeling

From the results of the related fit index assessment, the modified model chi-square statistic is 100.179, freedom degree is 78 and chi-square / freedom degree = $1.28 < 3$, indicating that the model fit is good. The approximation error RMSEA is $0.036 < 0.05$; absolute goodness of fit index GFI is 0.944, and the relative fit index CFI is 0.935. All the modified model indicators have reached the acceptable range, indicating that the structural equation model fit is better. From Figure 1, we can see that in the information construction of government's public sectors, public expectations directly influence public satisfaction, indicating that public expectations are the foundation of public satisfaction, and public satisfaction is the embody and destination of public expectations. Meantime, through the mediating variables, public satisfaction, public expectations indirectly affects the behavior of the public, showing that in the information construction of the government public sectors, if the public have a high expectation of government staffs, but the staff's attitudes and behaviors do not satisfy the public, then the expectations turning into disappointment which will finally lead to the public's behaviors out of control. At the same time, the author finds that public expectations will also affect the value of public perception. Through the intermediary variables, the perceived value affect the public, and ultimately affect the public's behaviors. Public expectations also affect public's service perception, and then through the mediating variables, public perceived value and satisfaction will ultimately affect the public's behaviors.

4 Conclusions

As for the influencing factors of the satisfaction of the government public sectors, according to the research results, this paper proposes the service management model for the purpose of improving public satisfaction. On the one hand, because through the mediating variables, public satisfaction, public expectations indirectly affect the behavior of the public, the government should adopt the service management model that is consistent with public expectations. With the development of the process of political democratization, the values of the public own department will be more and more obvious during the government reform. The status of the public own department and the relationship between the public and government are undergoing profound changes. Therefore, the type of democratic and open government is becoming a basic requirement of the public. The democratic ideals of modern government is presented that government behaviors must reflect the public will. Embodying the public will is the basic connotation of democracy, requiring government activities to respect citizens' interests and needs. Therefore, public satisfaction will become the ultimate indicator of the performance of government public sectors.

Research on Distribution Model Innovation of the Fresh Agricultural Products*

Li Shihua

School of Management, Wuhan University of Technology, Wuhan, P.R. China, 430070

(E-mail: lionlee007@aliyun.com)

Abstract: Within the fresh agricultural products distribution industry, it's an absolute trend that distribution model for fresh agricultural products have been constantly evolving from traditional ones to supply chain management style. Based on the analysis of the evolution mechanism of fresh agricultural products distribution model, differential models on those models have been constructed, the model evolution under government subsidies system has been analyzed and recommendations on policies for innovative development of fresh agricultural products distribution have also been made.

Key words: Fresh agricultural products; Evolution mechanism; Model innovation; Supply chain management

1 Introduction

With the development of urbanization, some big or media-sized cities suburb vegetable plots and retail outlets being running down steadily, increased links of commodity distribution and cost, “sells difficultly and buy dear” and so on the questions are going prominent. On December 13, 2011, the State Council office of the People's Republic of China has enacted a report about strengthening the fresh agricultural products distribution system^[1], which points out that China is the world's fresh agricultural products and consumption of power, so we must focus on strengthening the connection between production and marketing, strengthen the construction of infrastructure of fresh agricultural products distribution models, innovate the model evolution, meanwhile increase the degree of distribution organization, the distribution chain and market position must be perfected, further reduce the links of distribution, reduce the cost of distribution, through building the perfect, efficient, unblocked, safe and ordered fresh agricultural products distribution system, keep market supply and price stability of fresh agricultural products.

2 The Evolution Mechanism

With the development of modern logistics theory and practice, the practice of introduce the industrial product's new ideas and methods has been tried in the field of the fresh agricultural products logistics. In China, the fresh agricultural products' filed of production, distribution and consumption has undergone earthshaking changes, which pushing the economic development is being fostered and formed.

2.1 Practice of supply chain management

Logistics, as the third profit-point for enterprise, in order to achieve value-added logistics, it has cut the cost of logistics, improve customer care through various logistics rationalization. The practice of supply chain management is the most significant. By operating just-in-time strategy, rapid-response strategy, lean strategy and automation replenishment strategy and so on in the whole supply chains, it has advanced the performance of logistics, mean while minimized the cost of stock. The achievement of modern logistics in the filed of manufacturing industry and trade produced a profound effect on fresh agricultural products logistics, on one hand, it was perfectly possible that fresh agricultural products as the industrial stuff can integrate the manufacturing industry chain, on the other hand, fresh agricultural products as consumer goods start to try to supply chain management.

2.2 Specialization and commercialization of agriculture products

From the perspective of history, fresh agricultural products logistics promoted agriculture produce specialization and commercialization, meanwhile, the deepening of agriculture produce commercialization also raised higher requirements for fresh agricultural products. When the fresh agricultural products achieve commercialization, it must obtain value by realizing time and scope

* This paper is supported by Humane and Social Science Fund Project of Education Department for Hubei Province “Analysis of feasibilities and research of countermeasures of logistics outsourcing for agricultural products in Hubei province” (Project No.: 2010q055).

effectiveness created by the process of fresh agricultural products. Farmers who make a living on agriculture commercialization need not only to make their products shipped out, but also need to get accurate guidance from balanced and steady logistics activities, and get a steady income, so they need effective logistics activities.

2.3 Intervention of new retailing format

Supermarket chains have profound effects on fresh agricultural products management and fresh agricultural products management logistics. Based on the Supply Chain Management practice of other commodities, supermarkets are more accessible to the faith of fresh agricultural products management and put it into practice very quickly, such as the link between farmers and supermarkets model [2]. However the demands on fresh agricultural products’ standard, quality, levels and replenishment way managed by supermarkets become a new thing in fresh agricultural products logistics chain, which is being studied, delivered and applied in the whole chain.

2.4 Change of customer’s consumption structure and model

The changing of city consumption models make the tendency of current fresh agricultural products consumption packaging, super marketing, processing and ecological becoming more and more obvious, it creates conditions for fresh agricultural products logistics promoting to become modern, and provides a firm customers base for practicing fresh agricultural products logistics[3].

2.5 Application of the modern information technology

Because of the imbalance of the urban-rural dualistic structure, production and consumption matching shows a cyclical fluctuations for a long time, and information asymmetry, lags in information transmission, the whole fresh agricultural products logistics activities is habitual and traditional which is one of the reason why the fresh agricultural products distribution system’s coverage always be limited in a certain area. However the development of modern information technology completely changed this tradition, especially the application of Internet. Nowadays farmers can also view the international prices and domestic prices, so they could be confident to logistics market and have a support on measuring costs and benefits of logistics. The using of the modern information technology widens the range of logistics and promoted value added logistics formed. As shown in Figure 1:

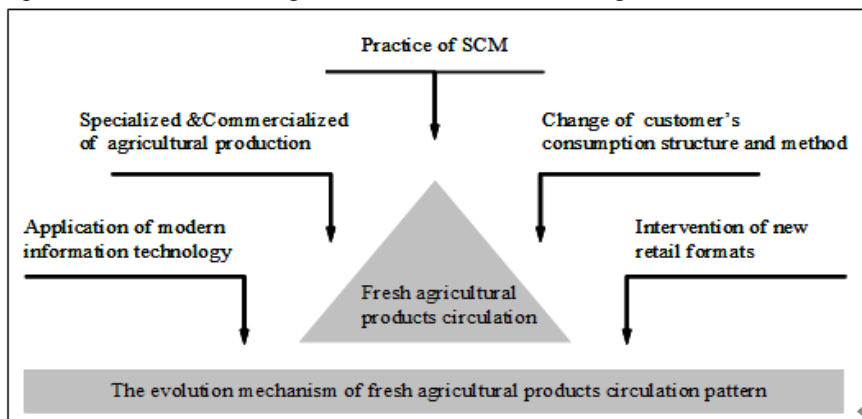

Figure 1 The Evolution Mechanism of the Distribution Model for Fresh Agricultural Products

3 Innovation of the Evaluation Model

3.1 Set up a model

In the fresh agricultural products differentiation market, A is the fresh agricultural products circulated through the supply chain management style, its safety degree is higher; B is the fresh agricultural products under the traditional style, its safety degree is lower. Supposing that consumers have different preferences for different degrees of fresh agricultural products safety, X is product security of consumer preference parameter, X in the interval [0, 1] obey uniform distribution. If the consumer only have the unit demand to the product, and dealers only have two options strategies: A and B. The definition of X for the consumer utility function is [4]:

$$U(x, s) = xs - p \tag{1}$$

Here s is safety, security refers to the products meet the food safety standards level, safety degree is high, the safety performance of fresh agricultural products is higher. Let A’s safety degree is s_1 , B’s safety degree is s_2 , $0 < s_2 < s_1$, and s_1, s_2 are fixed constant; p is price, let A’s price is p_1 , B’s price is p_1 (p_1 ,

p_2 are decision variables); x_0 is the preference parameter when consumers have no differences in consuming B and no consuming. So, $x_0s_2 - p_2 = 0$, then:

$$x_0 = \frac{p_2}{s_2} \tag{2}$$

Here x_1 is the preference parameter when consumers have no differences of A and B, so:

$$x_1s_1 - p_1 = x_1s_2 - p_2 \tag{3}$$

Then:

$$x_1s_1 - p_1 = x_1s_2 - p_2 \tag{4}$$

When $0 < x_0 < x_1 < 1$, we can get: the demand function of A and B is:

$$D_1(p_1, p_2) = 1 - \frac{p_1 - p_2}{s_1 - s_2} \tag{5}$$

$$D_2(p_1, p_2) = \frac{p_1 - p_2}{s_1 - s_2} - \frac{p_2}{s_2} \tag{6}$$

Supposing the relation between the fresh agricultural products safety and the distribution fixed costs is:

$C(s) = s^a, a > 1$, so

$$C'(s) > 0, C''(s) \geq 0 \tag{7}$$

This shows that the cost of improving fresh agricultural products' safety degree is increasing. This cost shows that quality and safety of fresh agricultural products is fixed costs, such as the equipment investment for fresh agricultural, technology investment and so on). Which have no connection with marginal cost, and without any consideration of the variable costs, so the profit function of A and B are:

$$\pi_1 = p_1 \left(1 - \frac{p_1 - p_2}{s_1 - s_2}\right) - C(s_1) \tag{8}$$

$$\pi_2 = p_2 \left(\frac{p_1 - p_2}{s_1 - s_2} - \frac{p_2}{s_2}\right) - C(s_2) \tag{9}$$

Combine:

$$\frac{\partial \pi_1}{\partial p_1} = 0, \quad \frac{\partial \pi_2}{\partial p_2} = 0 \tag{10}$$

We get the equilibrium price:

$$p_1^* = \frac{2s_1(s_1 - s_2)}{4s_1 - s_2} \tag{11}$$

$$p_2^* = \frac{s_2(s_1 - s_2)}{4s_1 - s_2} \tag{12}$$

The associated equilibrium quantity is:

$$q_1^* = \frac{2s_1}{4s_1 - s_2} \tag{13}$$

$$q_2^* = \frac{s_1}{4s_1 - s_2} \tag{14}$$

The corresponding maximum profit is:

$$\pi_1^* = \frac{4s_1^2(s_1 - s_2)}{(4s_1 - s_2)^2} - C(s_1) \tag{15}$$

$$\pi_2^* = \frac{s_1s_2(s_1 - s_2)}{(4s_1 - s_2)^2} - C(s_2) \tag{16}$$

Therefore, comparative profit between the fresh agricultural product distribution models and associated costs constitute the determinants of the distribution mode selection. In the course of the game, two kinds of distribution models between the profit margin larger, more conducive to the development of fresh agricultural product supply chain management mode, and vice versa.

3.2 The model evolution under government subsidies system

Considering the different product market, let:

$$y = \frac{s_1}{s_2} \tag{17}$$

Meanwhile assuming that the government paying subsidies to A according to its price, the subsidy rate is t , $0 < t < 1$, let $x=1+t$, right now profit function of the two models change to:

$$\pi_1^{**} = \frac{4xy(y-1)s_1}{(4y-1)^2} - C(s_1) \tag{18}$$

$$\pi_2^{**} = \frac{4s_1(y-1)}{(4y-1)^2} - C(s_2) \tag{19}$$

According to the first order conditions, dealers decide the standards of quality and safety for fresh agricultural products to obtain maximize profits. At the same time, in order to simplify the calculation process, take $\alpha=2$ (the different value of α depends on actual situation of fresh agricultural products distribution enterprises), so:

$$2s_1 = \frac{4xy(4y^2 - 3y + 2)}{(4y-1)^3} \tag{20}$$

$$2s_2 = \frac{y^2(4y-7)}{(4y-1)^3} \tag{21}$$

Depending equation 21, $4y-7 > 0$, divides the two postures we can get:

$$y = \frac{4x(4y^2 - 3y + 2)}{y(4y-7)} \tag{22}$$

With respect to X, one gets:

$$\frac{dy}{dx} = \frac{4(8y-3)(4y^2 - 3y + 2)^2}{y[y(16y^2 - 24y + 19) + 4y(4y-7)]} \tag{23}$$

$4y-7 > 0$, one gets as well:

$$\frac{dy}{dt} > 0 \tag{24}$$

This shows that the implementation of government subsidies for A will increase the differences between the two kinds of fresh agricultural products that is to say that the government subsidies help improve the enthusiasm of dealers for fresh agricultural product, to make them gain more profits, and then promotes distribution models for fresh agricultural products from traditional ones to supply chain management style^[5].

4 Results

Through the above analysis, we draw the following results: For one thing, the social and economic background, industry and Commerce in the field of modern logistics practice achievements and characteristics of fresh agricultural products logistics combination, provides analysis framework for these modern fresh agricultural products logistics strategy choice. Within the fresh agricultural products distribution industry, it's an absolute trend that distribution models for fresh agricultural products have been constantly evolving from traditional ones to supply chain management style.

For another thing, in the evolution of different distribution model of fresh agricultural products in the process, the government mechanism is positive and effective. Through the implementation of government subsidy mechanism can make the evolution process of fresh agricultural products distribution smoothly.

5 Conclusions

In view of the current practice of fresh agricultural products in China have channel disorder, delivery time, many links, high cost, high cost, low efficiency problems^[6], the traditional fresh agricultural product distribution is still mainly distribution models of households, we wish to make the following proposals and conclusions:

First of all, further improve the agricultural product distribution organization and modernization level, focus on cultivating a number of third party logistics enterprises engaged in large fresh agricultural products distribution.

Second, strengthen marketing docking, reduce the circulating link, actively try to take “farmers + company”, “agriculture super direct supply” of fresh agricultural products supply chain collaborative management mode.

Third, increase policy to the fresh agricultural product distribution system support, increase financial input, carry out targeted subsidies, encourage the innovation and development of the fresh agricultural products logistics mode.

Coupling Mechanism Between Sports Industry and Ecological Environment in the Low-Carbon Economic Era

Zhao Ying

Sports Department, Wuhan University of Technology, Wuhan, P.R. China, 430070
(E-mail: chenhuilin0127@163.com)

Abstract: The double restraint of resource and environment has made low-carbon economy a global trend, which will become a new way of production and life style. As two independent systems, only the sports industry and ecological environment keep coordinated with each other can they ensure their own good operation and realize common development. Under the background of low-carbon economic era, this article comprehensively analyzes the relations between sports industry and ecological environment, studies the coupling mechanism between them, and gives some policy recommendations to improve their coupling, which has important realistic meanings.

Key words: Low-carbon economy; Sports industry; Ecological environment; Coupling mechanism

1 Introduction

Low-carbon economy is becoming a new trend of the global economy. Guided by sustainable development concept, it is a kind of economic mode which can be best characterized by low pollution, low energy consumption and low emission, using technological, institutional and organizational innovation to minimize the carbon emission. The ecological environment preservation is a global social issue in the low-carbon economy era; therefore, the relation between social development and ecological environment has become a hot topic that has been studied by different disciplines. Sport is a special kind of cultural phenomenon that lies in the whole sociocultural environment. It is a kind of subculture, playing an important role in coordinating society and environment. The sport industry affects the city environment and in turn, the city environment restricts the operation and development of sport industry. Therefore, fully developing the function and potential of sport, revealing its mediate function, and exploring a way of boosting the synergetic development of society and environment is a topic that has important theoretical significance and practical value, needed to be taken seriously.

2 Correlation Analysis between Sport Industry and Ecological Environment in Low-carbon Economy Era

Sport is an intermediate system, whose function of coordinating the society and ecological can be reflected in two ways: one is to improve health and the other is to promote the productivity. The coordinated development of society and environment is not a once-for-all thing but a dynamic process that conflicts constantly engender and get solved.

2.1 Influence of sport on ecological environment

During the process of sport, people would acquire goods and materials from the ecological environment directly or indirectly, such as the place or information that sport may need and those things have great impact on the development of sport. The ecological environment varies a lot between countries and regions, but the pursuit of sport and the use of ecological environment is the same.

(1) Influence of sport on natural environment. Natural environment means those natural conditions such as topography, location, climate etc. which can directly influence the life of people. During the process of development of sport, the choosing of specific items, contents and scales is restricted by the natural environment. In recent years, with the prosperity of large-scaled sporting events like Olympic Games, the status of sport in socioculture is rising; the passion of exploiting natural environment has been stimulated; emerging sports such as golf, bathing place, surfing, water items, and alpine skiing etc. are becoming popular gradually; and dramatic changes have taken place in sports and geographical features. In addition, the constant emerging of sport facilities, stadiums, advertising and logos is changing the human geography.

(2) Influence of sport on biological environment. All the outdoor sports get started under some certain kind of biological environment. Sport relies heavily on the spatial conditions that biological environment provides, such as green screen of physical fitness activities, and the grassland etc. In other words, if biological environment were to be spoiled, sports activities would be affected. So during the process of developing sports activities, biological environment should be protected properly. We should

ensure that people's subjective initiative be brought into fully play and in the same time, should not go against nature, which means sport should get as much coordinated with natural environment as possible. When carrying out activities like sport tourism, sport facilities and sport entertainment, we should fully consider the surrounding biological environment and prevent to seek quick success and instant benefits to develop sport activities by sacrificing the biological environment such as plants and lakes that we human rely on for living. Otherwise, modern sport activities can hardly get sustainable development. A case in point is that Denver (USA) gave up the opportunity of holding the 12th Winter Games in 1972 because of the strong resistance from the local ecological organization. And for the same reason, Vancouver (Canada) dropped out from holding of the 13th Winter Game in 1974 as well.

2.2 Influence of ecological environment on sport

Sport activities are restricted by natural environment such as climate, geography and locations, and the types and forms of sport differentiate because of the natural environment, therefore, the performance of sport competition relates closely to the natural environment. Besides, the constant pollution of air, water, earth and noise will endanger athletes' health as well. For instance, photochemical smog will stimulate respiratory mucosa and eyes, which cause great damage to those eyesight-required activities such as archery, shooting and ping-pong. Another case in point is that currently the water pollution is serious, in which there is phenol and oil that may cause damage to kidney, liver and nervous system, or even endanger health. In addition, the damage of noise should not be overlooked as well. It will harm the athletes' cardiovascular system, cause disorders of autonomic nervous system, lead to disfunction of energy supply system and nervous system, affect the rest and sleep quality of the athletes, and finally result in the disordered performance. As a result, here comes the concept of "green sport", which advocates the accord development of sport and nature—only a pollution-free environment can promote the sustainable development of sport.

Anyway, there is a correlation between the sports industry and the environmental protection in China. In one way, sports industry brings huge pressure and threat to environmental protection; in another, it spreads the green concept and environmental culture, promoting the continuous development of environmental protection. In the meanwhile, the improvement of ecological environment not only is the driving force and foundation of sports industry, but also provides resources to support it. Therefore, sports industry should integrate with environmental protection and finally we can achieve the harmonious development of both.

3 Coupling Mechanism Between Sports Industry and Ecological Environment in Low-Carbon Era

3.1 The connotation of coupling between sports industry and ecological environment

As one of the basic concept of physics, coupling is a phenomenon of mutual interaction of two or more modes of motion or systems. It is a dynamic correlation of inter-coordination, interdependence and mutual promotion by positive interaction of each system. Similarly, in low-carbon era, coupling apparently lies in sports industry and ecological environment. They affect each other, and form a good interactive internal relationship. Therefore, the coupling between sports industry and ecological environment is just the interaction between sports and environmental protection, meaning as followed:

(1) Emphasis on combination of sports and natural environment. When developing sports industry, we should guide people to gradually change the traditional psychology of seeking knowledge, pleasure and innovation to the psychology of returning to nature. Exercising is no longer the only demand of sports, but the pursuit of sports environment such as nature, comfort, spaciousness and brightness is more and more valued.

(2) Constant exploration of ecological value of national sports. Most of the national sports have inherent connection with nature, and they pursue the concept of "from nature" and "into nature". Therefore, in today's society whose sports industry is boosting, it is necessary to rebuild the national sports which are closely connected to nature, and actively build a coexisting ecological environment.

(3) Advocacy of ecological sports development concept. When developing sports industry, we should not only pay attention to the sports own functions and values, but also need to focus on the mutually beneficial coexistence and the harmonious development among "people- nature- society-sports", that is a comprehensive sustainable development of sports benefit, social benefit and ecological benefit. To advocate the concept of ecological development is a trend for human race's own development and perfection, and is also a necessity for harmonious development with nature.

3.2 The process of coupling between sports industry and ecological environment

The coupling between sports industry and ecological environment is a process of both systems from disorder to coupling to disorder and to coupling again and this kind of constant recycling has constituted a spiral movement of the social system. Actually it is an evolution and development of a large-scale complex system, which is altogether made up by slow and sudden changes, just as shown in figure 1.

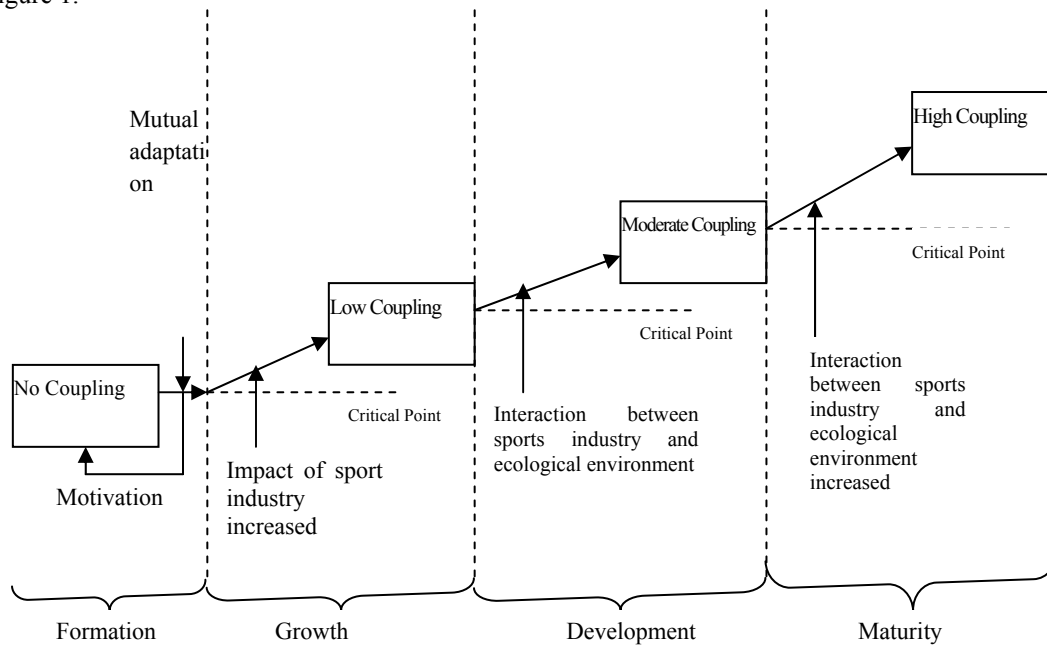

Figure 1 Coupling Progress of Sports Industry and Ecological Environment

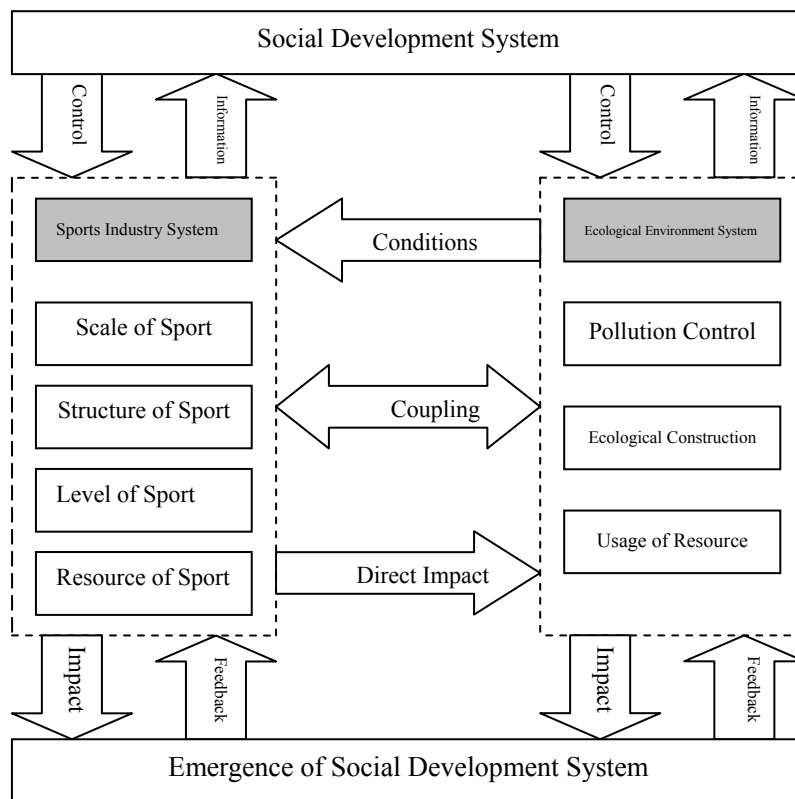

Figure 2 Coupling Model of Sports Industry and Ecological Environment

From figure 1, the coupling progress can see four stages: formation, growth, development and maturity. Every leap from to lower stage to the higher one requires some driving force to complete the transition from slow changes to sudden changes. Meanwhile, the coupling level of sports industry and ecological environment is rising and the relationship between them is becoming more coordinated. When the coupling system has reached a certain stage, there would be a sudden change of the system owing to a tiny disturbance; therefore, it would finally lead to a truly highly coupling stage. It is just because of this kind of sudden change that we need to establish a matching sports industry by using the operation rules of the social system. In addition, after the early coupling, by interfering with the related factors, we should create an ecological environment which is suitable for the high-degree coupling to finally achieve the emerging of the system and promote the sustainable development of sports industry, shown as in figure 2.

The system of sports industry and ecological environment can be divided into the following four parts: first of all, the coupling of the sports industry's scale and the endurance of ecological environment, that is the coupling of scale; Secondly, the coupling the structure of sports industry and the status quo of ecological environment, that is the coupling of structure; thirdly, the level of sports which can meet the requirement of the development and the upgrading of ecological environment, that is the coupling of ability; lastly, the facilities of sports which can adapt to the ecological environment, achieving reasonable allocation, that is the coupling of resources.

4 Conclusions and Policy Suggestions

4.1 Conclusions

(1) All the sports activities should start from the harmonious relationship between human and environment, looking for the balance between environment and development- only environmental protection can ensure the sustainable development of society.

(2) There is a close correlation between the development of sports industry and environmental protection. We should explore the function and potential of sport to improve the construction and development of ecological environment and in turn, make good use of environment to better develop the sports industry.

(3) In the low-carbon era, the coupling of sports industry and ecological environment is apparent. They affect each other and form a positive internal interaction between them. The coupling process needs to go through four different stages- formation, growth, development and maturity, which can be realized in the aspect of scale, structure, ability and resource.

4.2 Policy suggestions

(1) Establish the concept of ecological sports. Actively cater to the requirement of low-carbon, saving energy and reduce emission. Use the ecology awareness of people and the ecological construction around the facilities and during the events to evaluate the success of the events and the qualifications of the related administrative department.

(2) Optimize the structure. Pay attention to the upgrading of the structure and the mode of sports industry and highlight its advantages and characteristics, gradually achieving the reasonable allocation of industrial structure; attach importance to the ecological construction of the surrounding living area and its pollution governance.

(3) Pay attention to the guidance of function. Clarify the direction of sports industry according to the requirement of regional development and adapt to the impact that sports industry exerts on ecological environment, promoting each other.

Abstract: To better understand how collaborative learning in social networks affects the performance of natural resource governance, different characteristics of different social network structures should be determined. However, prior findings related to the impacts of structural differences of collaborative learning on the performance of natural resource governance are limited and obscure at both the level of whole network and the level of individual actors. Suitable forms of organization for collaborative learning in social networks are critical to acquire and share information, percept and adapt risk, absorb and create knowledge, which has not been comprehensively addressed in existing research literatures. In order to challenge the vacancy, this paper modifies the triple-loop collaborative learning model based on previous studies and then finds the most suitable organization forms for collaborative learning at different structures of social networks after practical investigation.

Key words: Collaborative learning; Social network structures; Organization forms; Natural resources governance; MANOVA test.

1 Introduction

Previous studies show significant differences in performances and processes of natural resource governance when social networks go through structural differences in terms of density of relations (Little and McDonald, 2007)^[1], degree of cohesiveness (Borgatti and Foster, 2003^[2]; Moller et al., 2004^[3]), subgroup interconnectivity (Davidson-Hunt, 2006)^[4]. Specifically, identification of alternative strategies and actions to resolve specific problems and to improve certain outcomes such as improved incomes and higher yields are typical characteristics of single-loop learning (Armitage et al., 2008^[5]; Huntjens et al.,2012^[6]). On the contrary, double-loop learning involves challenges of existing worldviews and underlying values, such as a shared reconsideration of the goals of a management process, which also changes stakeholder behaviors. The transparency required to test and challenge embedded values, active engagement with civil society, a willingness to take risks in order to extend learning opportunities, and a high degree of citizen participation are characteristics of double-loop learning encouraged by institutional and organizational frameworks (Diduck et al.,2005)^[7]. The triple-loop learning starts to pay attention to the norms and protocols upon which single-loop and double-loop learning are monitored and learned. In order to stimulate the changes of the underlying governance system, learning provides a reflective mechanism when designing those norms and protocols (Keen et al.,2005)^[8]. Further study has found that relative credibility and legitimacy of information sources are the most important links between social network and perception of information, risk perception and adaptation (Frank et al., 2011)^[9].

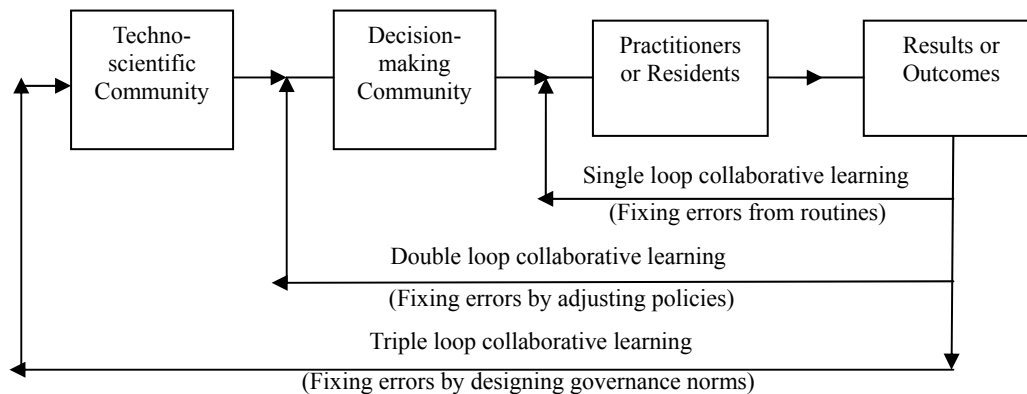

Figure 1 A Multiple-Loop Collaborative Learning Framework

From the mentioned above, Figure 1 describes the modified multiple-loop collaborative learning model within social networks for environmental and resource management. These outcomes are especially important because it consists of the intentions and actions which prompt changing routines, altering underlying policies, and developing innovative governance norms.

However, extensive studies have not discussed thoroughly about the suitable forms of organization for collaborative learning in social networks, which are critical to acquire and share information, percept and adapt risk, absorb and create knowledge (Dodgson, 1993^[10]; Song et al., 2006^[11]). In order to fill the gap in the existing literature, the rest of the paper is organized as follows: Section 2 makes some proposed hypotheses based on the modified triple-loop collaborative learning model. Section 3 analyzes the collected data and discusses results. Finally, conclusion is provided in section 4.

2 Proposed Assumptions

In general, the forms of organization for collaborative learning in social networks are divided into five categories including 1) a sequential function for collaborative learning: acquiring and sharing information, identifying and adapting risk, absorbing and creating knowledge within each stage, and then transferring knowledge to the next procedure automatically; 2) a central function for collaborative learning: a team of specialists headed by a chief officer is in charge of knowledge-related governance of natural resources in all development projects; 3) a project-decentralized task force for collaborative learning: a task force headed by a leader reporting to the project manager is in charge of knowledge-related governance of natural resources that are internal to each development project; 4) functionally located cells for collaborative learning: developing knowledge in support of projects development and disseminating knowledge to project groups, it is the responsibility of a cell within the specialized functional project; 5) a matrix function for collaborative learning: acquiring and sharing information, identifying and adapting risk, absorbing and creating knowledge automatically and simultaneously within all procedures (Brown and Duguid, 2000^[12]; Cooper et al., 2002^[13]; Chen and Pang, 2010^[14]). The interactive linkage among partners including scientists, policy-makers, and practitioners needs to be understood so as to effectively acquire and share information, percept and adapt risk, absorb and create knowledge, based on different stages. Thus, the following assumptions are carried out: Assumption (a), when building collaborative learning in social networks, the most suitable form of organization in the stage of scientific community is a central function. Assumption (b), when building collaborative learning in social networks, the most suitable form of organization in the stage of policy-making community is a project-decentralized task force. Assumption (c), when building collaborative learning in social networks, the most suitable form of organization in the stage of practitioners' community is functionally located cells.

3 Research Methodologies

3.1 Data collection

The purpose of questionnaire is to assess critical characteristics of social network for effective governance in the environmental change, and then select suitable forms of organization for collaborative learning. A self-administered questionnaire was distributed to scientific community (including researchers and scholars in research institutions and universities), policy-makers (including local and national development and reform commission, local and national environmental protection agency) and practitioners (including farmers, fishers and industrialists). Answered questionnaires were collected with a total number of 9348, including scientific community (23%), policy-making community (31%), and practitioners (46%). Meanwhile, the number of 5675 usable answered questionnaires reflecting a response rate of 60.71%. Respondents were from scientific community (32%), policy-making community (35%), and local practitioners (33%). After data collection, SPSS v19 software package was conducted to deal with multivariate statistical analysis.

3.2 Data analysis and discussion

In order to reduce the set of variables to a more manageable set of scales, this paper uses principal component analysis (PCA) to find out the underlying dimensions representing critical characteristics of social network. In the second step, MANOVA and post-hoc tests are adopted to compare different forms of organization with respect to scientific community, decision-making community and local practitioners at different structures of social networks.

3.2.1 Cluster analysis of the most important extracted factors:

9 questions about how important each named group of social networks for different network

structures, including low cohesive, high cohesive and core-periphery network structure, are asked using a 5-point Likert scale ranging from 1 = extremely unimportant to 5 = extremely important. Table 1 illustrates that respondents within different network structures have specific relationships with different characteristics of social networks. Except for “need to innovation”, “better enabling technology” and “improving performance” which show low cohesive network structure, high cohesive network structure and core-periphery network structure significantly differ at 5% level. In contrast, “dispersion” and “propensity to change” are the most important characteristics for network structure with low cohesiveness. The consequences are meaningful as actors who belong to this structure show low cohesion both in internal community and external communities. They hold different attitudes and pose challenges for joint action. Meanwhile, “regulation” and “minimizing uncertainty and risk” are the most important characteristics for core-periphery network structure. The results make sense because actors in the structure show high cohesion plus strong tying bond within internal actors, but high cohesion plus distant tying bond among external actors. So, they try to build regulation for governance of natural resources and transfer knowledge in order to reduce uncertain risk. Moreover, the most important characteristics are “mutual relationship” and “interdependence” for high cohesive structure. It is apparent that actors in high cohesive structure show high cohesion within internal and external actors. The results seem reasonable since subgroup is difficult to distinguish and the relational ties among groups are high in this structure.

The answered questionnaires are divided into three groups including low cohesive, high cohesive and core-periphery network structure for subsequent investigation. Then, 9 questions about suitable forms of organization for collaborative learning in different network structures also employed a 5-point Likert scale ranged from: 1 = ‘not highly recommended’, 3 = ‘no comment’, 5 = ‘highly recommended’.

Table 1 Respondents with Different Network Structures

The Most Common Structure & Most Important Factors	Low Cohesiveness	Core-periphery Structure	High Cohesiveness	F (or K)	
<i>Mutual Relationships</i>					
Cluster Mean	1.86 ^a (2,3) ^b	2.86(1,3)	4.08(1,2)	10.32 ^c	p<0.052
<i>Propensity to Change</i>					
Cluster Mean	3.86(2,3)	2.73(1,3)	1.83(1,2)	13.52 ^c	p<0.036
<i>Interdependence</i>					
Cluster Mean	2.09(2,3)	3.12(1,3)	4.23(1,2)	15.35 ^c	p<0.030
<i>Better Enabling Technology</i>					
Cluster Mean	2.41	2.63	2.92	5.52 ^c	p<0.103
<i>Need to Innovation</i>					
Cluster Mean	3.26(3)	2.98(3)	1.91(1,2)	7.32 ^c	p<0.076
<i>Regulation</i>					
Cluster Mean	2.40(2)	3.61(1,3)	2.51(2)	18.81 ^c	p<0.021
<i>Minimizing Uncertainty</i>					
Cluster Mean	1.93(2)	3.58(1,3)	1.86(2)	10.52 ^c	p<0.047
<i>Improving Performance</i>					
Cluster Mean	2.73(2)	3.47(1,3)	3.09(2)	4.39 ^c	p<0.128
<i>Dispersion</i>					
Cluster Mean	3.95(2,3)	2.81(1,3)	1.79(1,2)	12.27 ^c	p<0.039

Note a: Mean based on 5-point Likert scale comparing the data collected in the beginning of 2012.

Note b: Numbers in parentheses indicate the cluster groups from which this cluster is significantly different at $\alpha=0.05$ according to the Bonferroni, post-hoc pairwise comparison procedures.

Note c: F and corresponding p-values based on MANOVA test.

3.2.2 Cluster analysis of network structure with low cohesiveness:

Table 2 describes suitable organization forms for low cohesive network structure. In the first place, project-decentralized task force, followed by a central function, has been regarded as the best form of organization for scientific community. Although government in China has asserted that stricter environmental management is carried out, the actual situation is still far behind US or Europe countries. It is important for actors to improve the level of knowledge transfer among internal and external actors, and learn advanced knowledge from international leading scientific institutions. Therefore, suitable form with strong transferring of knowledge among actors and strongest alignment with the strategic policies can be regard as the most excellent one. Assumption (a) is proved to be partly held. Besides, project-decentralized task force is viewed as the best form of organization for policy-making community

and actors in this stage are required to transfer knowledge within internal and external actors actively. Thus, suitable form which provides the highest potential for supporting transfers and sharing of knowledge within internal as well as external actors is the excellent one. Assumption (b) is proved to be fully held. Furthermore, a project-decentralized task force followed by functionally located cells is the best form of organization for local practitioners. Experiences related to governance of natural resources equally come from external and internal actors. Then, the suitable form should be one which provides knowledge share among external actors, knowledge related to specific expertise and knowledge transfer within internal actors. Assumption (c) is proved to be partly held.

Table 2 Suitable Organization Forms for Low Cohesive Network Structure

Stages of low cohesive structure & Suitable Forms of Organization	Scientific Community	Policy-making Community	Local Practitioners	F (or K)
<i>A Sequential Function</i>				
Cluster Mean	1.76 (2,3)	1.97(1)	1.72(1)	3.79 ^c p<0.096
<i>A Central Function</i>				
Cluster Mean	3.34 ^a (2,3) ^b	2.39(1)	2.41(1)	10.37 ^c p<0.051
<i>A Project-decentralized Task Force</i>				
Cluster Mean	3.87(3)	4.04(1,2)	3.78(3)	11.49 ^c p<0.041
<i>Functionally Located Cells</i>				
Cluster Mean	2.33(3)	2.45(3)	3.43(1,2)	15.98 ^c p<0.024
<i>A Matrix Function</i>				
Cluster Mean	1.24(3)	1.80(3)	2.23(1,2)	3.82 ^c p<0.103

Note a: Mean based on 5-point Likert scale comparing the data collected in the beginning of 2012.

Note b: Numbers in parentheses indicate the cluster groups from which this cluster is significantly different at $\alpha=0.05$ according to the Bonferroni, post-hoc pairwise comparison procedures.

Note c: F and corresponding p-values based on MANOVA test.

3.2.3 Cluster analysis of core-periphery network structure:

Table 3 Suitable Organization Forms for Core-Periphery Network Structure

Stages of Core-periphery structure & Suitable Forms of Organization	Scientific Community	Policy-making Community	Local Practitioners	F (or K)
<i>A Sequential Function</i>				
Cluster Mean	2.36(2)	1.98(1,3)	2.73(2)	4.18 ^c p<0.095
<i>A Central Function</i>				
Cluster Mean	3.87 ^a (2,3) ^b	2.52(1,3)	1.94(1,2)	15.52 ^c p<0.031
<i>A Project-decentralized Task Force</i>				
Cluster Mean	2.41(2,3)	4.05(1)	3.79(1)	12.47 ^c p<0.043
<i>Functionally Located Cells</i>				
Cluster Mean	2.35(3)	2.31(3)	3.48(1,2)	10.46 ^c p<0.056
<i>A matrix Function</i>				
Cluster Mean	2.75	3.14	2.86	3.29 ^c p<0.107

Note a: Mean based on 5-point Likert scale comparing the data collected in the beginning of 2012.

Note b: Numbers in parentheses indicate the cluster groups from which this cluster is significantly different at $\alpha=0.05$ according to the Bonferroni, post-hoc pairwise comparison procedures.

Note c: F and corresponding p-values based on MANOVA test.

Table 3 illustrates suitable organization forms for core-periphery network structure. Firstly, it shows that a central function is the best form of organization for scientific community, and international leading scientific institutions have advanced knowledge for actors to learn from. Then, providing the strongest alignment with the strategic policies is the task for the suitable form. Assumption (a) is proved

to be fully held. Secondly, for the policy-making community, the best form of organization is a project-decentralized task force and actors in this stage need to actively transfer knowledge within external actors. After that, the suitable form is required to provide the highest potential for supporting transfers and sharing of knowledge among external actors. Assumption (b) is proved to be fully held. Thirdly, it points out that functionally located cells are the best form of organization for local practitioners. Exchanging knowledge with internal actors, they can obtain experiences related to governance of natural resources. Therefore, knowledge with specific expertise and strong transferring within internal actors are the key factors for a suitable form. Assumption (c) is proved to be held.

3.2.4 Cluster analysis of network structure with high cohesiveness:

Table 4 indicates suitable organization forms for high cohesive network structure. To begin with, it shows that the best form of organization for scientific community is a central function, followed by a project-decentralized task force. Actors in this stage need to learn advanced knowledge from international leading scientific institutions. Then, the suitable form should provide strongest alignment with the strategic policies. Assumption (a) is proved to be fully held. In addition, it shows that the best form of organization for policy-making community is a project-decentralized task force. The highest potential for supporting transfers and sharing of knowledge among external actors should be provided. Assumption (b) is proved to be fully held. Finally, it shows that the best form of organization for local practitioners is a project-decentralized task force, followed by functionally located cells. Experiences learning from external actors should be reinforced. Assumption (c) is proved to be partly held.

Table 4 Suitable Organization Forms for High Cohesive Network Structure

Stages of high cohesive structure & Suitable Forms of Organization	Scientific Community	Policy-making Community	Local Practitioners	F (or K)
<i>A Sequential Function</i>				
Cluster Mean	2.33	1.86(1,3)	2.27	4.29 ^c p<0.097
<i>A Central Function</i>				
Cluster Mean	3.79 ^a (2,3) ^b	2.83(1)	2.65(1)	11.27 ^c p<0.048
<i>A Project-decentralized Task Force</i>				
Cluster Mean	2.94(2)	3.54(1,3)	3.06(2)	10.04 ^c p<0.054
<i>Functionally Located Cells</i>				
Cluster Mean	2.46	2.32	2.86(2,3)	4.32 ^c p<0.092
<i>A Matrix Function</i>				
Cluster Mean	1.29	2.43	1.92	3.64 ^c p<0.108

Note a: Mean based on 5-point Likert scale comparing the data collected in the beginning of 2012.

Note b: Numbers in parentheses indicate the cluster groups from which this cluster is significantly different at $\alpha=0.05$ according to the Bonferroni, post-hoc pairwise comparison procedures.

Note c: F and corresponding p-values based on MANOVA test.

4 Conclusions

From a managerial point of view, a hierarchical structure of suitable organization form for collaborative learning in social networks should be proposed and shown in Figure 2 (modified from Chen and Pang, 2010^[14]). A hierarchical structure is important for the suitable organization form since actors may experience many projects related to governance of natural resources. In the first tier, the centralized structure provides the strongest guidance between strategic policy and collaborative learning initiatives, the best coordination and communication of collaborative learning activities, and the clearest understanding of responsibilities by actors. As to centralized structure, it not only offers a good overview of needs, but also has ability to quickly distribute knowledge about similar activities within internal actors and among external actors. In the second tier, with the executive and strategic needs, project-decentralized task forces enable rapid and pragmatic testing of the contributions of the collaborative learning initiatives. In the project-decentralized task, it shares inter-functional knowledge by providing the highest potential for transferring and sharing of implicit knowledge as well as explicit knowledge within internal actors and among external actors. In the third tier, the functionally located cells situated at the lowest level can focus on specific expertise and easily transfer knowledge within and between practical experiences. However, under the strategic alignment and operational management, the

functionally located cells may cause a vague vision and high uncertainty.

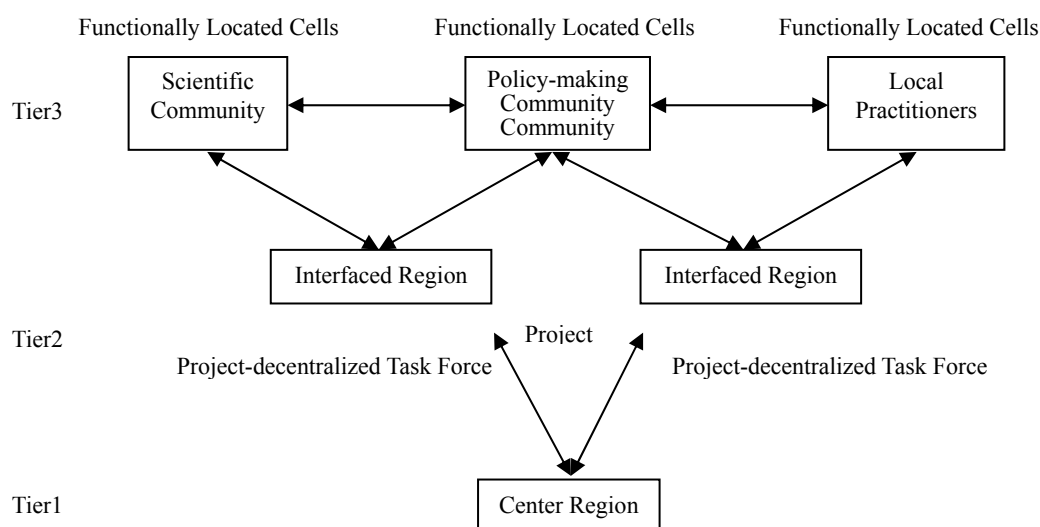

Figure 2 Suitable Forms of Organizations for Collaborative Learning

In fact, the hierarchical structure of suitable organization form for collaborative learning should be adjusted according to the change of environments actors may face. Specifically, characteristics of governance of natural resources like ecological threats, technological and scientific advancement, and social change are similar to the green area management. Then, in order to acquire and share information, percept and adapt risk, absorb and create knowledge, functions about the centralized structure should be reinforced in the low cohesive network structure, functions about project-decentralized task forces should be intensified in the core-periphery network structure, and functions about the functionally located cells should be reinforced in the high cohesive network structure.

(E-mail: jiangbinzhu@gmail.com, xddzzj@163.com, wangchong19901223@gmail.com)

Abstract: Perceiving the key elements and indices of emergency management capability properly is an important premise to government's ability building. This paper adopts literature method to summarize the key elements of Chinese government emergency management capability of major public health paroxysmal incident. Based on 168 responses from a survey distributed to five city of Hubei province of China, this study provides a confirmatory factor analysis. The findings suggest that the key indices of Chinese government emergency management capability lie in comprehensive decision-making, leading group command, resources allocation, diseases control and information-communication. In addition, the relations between elements and indices are discussed as well. This study provides theoretical references to the key contents of government emergency management capability building in China.

Key words: Major public health paroxysmal incident; Government; Emergency management capability; Key index; Confirmatory factor analysis

1 Introduction

Major public health paroxysmal incidents like SARS, the avian influenza and A (H1N1) have become a worldwide concern in recent years. Governments' role has long been considered a linchpin by acting as main subjects to respond to it, the strength of their emergency management capability is closely related to the control, relief and elimination of severe harm brought by public health paroxysmal incidents. As a result, perceiving the concept of government emergency management capability properly and figuring out its key elements and indices becomes significant questions.

The fundamental research on government emergency management capability of major public health paroxysmal incident mainly focuses on the connotation (George D. Haddow & Jane A. Bullock, 2003; Yang Qing, 2007), assessment indices (Bonnie Henry & Tomislav Svoboda, 2004) and ability building (Scott F. McClellan, 2004) of emergency management capability. However, there are two problems in the existing indices design: the lack of scientificness in the content of indexes; the challenge to the logicity of the framework. Research about measurement index based on elements is insufficient. This paper takes government emergency management capability as the object of study. According to the pertinent literature, it summarizes the key elements. Then a survey distributed to five city of Hubei province of China was conducted to collect data for refining the key indices of Chinese government emergency management capability by confirmatory factor analysis.

2 Elements of Government Emergency Management Capability

A number of scholars have discussed government emergency management capability of major public health paroxysmal incident from different perspectives. In the terms of decision-making, the decisions on emergency disposal need to be mainly made by departments in charge of the major public health paroxysmal incident, while others give assistance at the same time (JANIS I L, 1989). In addition, chief executive, as the commander, plays an absolutely important role in paroxysmal incidents. In the United States, Capability Assessment for Readiness put forward by FEMA consists of thirteen emergency management functions (James LW, 1997). Conducting is included. As for emergency resource, it is overall and adequate resource reserve that being the crucial foundation and element of emergency operation (Feng Baixia, 2006). Furthermore, different major measures should be taken to control the disease according to the different phases (Koji Wada, 2010), this paper summarizes it as diseases control capability. In these years, developed countries are attaching importance to the construction of emergency network. To increase network sustainability, emergency management collaborative networks should invest in information-communication technologies (Naim Kapucu & Vener Garayev, 2013). For international cooperation, with the deeper development of globalization, the

* This paper is supported by Natural Science Foundation of China "Measurement Evaluation System and Empirical Study on Government Response Capacity of Major Public Health Emergencies" (71003079).

cooperation between countries and international organizations tends to be mature. European Union, for instance, assessed the collaboration between its member states and international institutions during the period of A (H1N1) (Rory Watson, 2007).

In conclusion, on the basis of related literature on government emergency management capability, this paper takes Chinese government emergency management status quo into account and summarizes the six following key elements: comprehensive decision-making, leading group command, resources allocation, diseases control, information-communication and international cooperation capability.

3 Methodologies

To figure out the indices of the above key elements, a survey consists of blocks of questions which are measured on a 5-point Likert-type scale was implemented. Using project analysis, exploratory factor analysis and confirmatory factor analysis, this study got key indices of government emergency management capability.

3.1 Measuring tool

The government emergency management capability (GEMC) scale includes six constructs. There are five items belong to comprehensive decision-making capability, five to leading group command capability, eleven to resources allocation capability, five to diseases control capability, five to information-communication capability and one to international cooperation capability, thirty-two in total.

3.2 Data collection

Adopting convenience sampling, this study employs data derived from responses to the GEMC that was electronically mailed to agencies responsible for emergency management in Wuhan, Jinmen, Ezhou, Wuxue and Danjiangkou City, Hubei province of China. During the pretest, a total of 107 (130 total) responses were collected, among which 100 were eligible for analysis after data clearance. After the revise according to the pretest, 184 (200 total) responses were collected, 168 were eligible for analysis.

3.3 Project analysis

The first, all the indices passed through the descriptive statistics analysis, with no error value beyond 1-5. The second, in the confidence interval of 95%, the T value of government's taking advice from "the masses" (Sig.=0.144) and "others" (Sig.=0.326) were deleted for not reaching significant level. The third, during the homogeneity test with the total points, the correlation indices of taking advice from "the masses", "media comments" and "others", the existence of specialized command authority and good segregation and disinfection are less than 0.4, being rejected.

3.4 Exploratory factor analysis

Conducting exploratory factor analysis twice through different method, it extracted six common factors. After deleting the indices of "rapid information release" and "international coordination system", whose factor loadings are 0.447 and -0.404, respectively. This paper finally determined five common factors. The ultimate indices constructs utilized in the study have the Cronbach's alpha reliability values of 0.903, showing the high stability and consistency of the GEMC scale.

3.5 Confirmatory factor analysis

On the basis of the revised scale with five key elements and twenty-five variables, this study utilized confirmatory factor analysis through AMOS 21.0 to ensure the suitability between the data and model. As the estimate value less than 0.4 does not meet the standard, this paper deleted six items in sequence. Consequently, there are nineteen variables left for confirmatory factor analysis.

4 Findings

The analysis shows that the hypothesized model fit the sample data well. It not only indicates the relations between all the elements, but gives the key indices of government emergency management capability and their relevance.

4.1 Hypothesized model and sample data fitness

To modify the model, AMOS provides two kinds of solutions: modification indices (MI) for model extension and critical ratio (CR) for model trimming. As both of the CR value reaches significant level, this study chose to extend the model. Ranking MI value in descending order, this paper added path between e15 and e16, e7 and e9 successively. The improvements on model fit indices are reflected in Table 1. The value of CMIN/DF, NFI, PNFI and PGFI meet the standard, while CFI, RMR, GFI and RMSAE close to the standard. With half of the indices standard, the result of confirmatory factor analysis shows that the measurement model is relatively reliable.

Table 1 Model Fit Indices

Model fit indices	CMIN/DF	NFI	CFI	RMR	GFI	PNFI	PGFI	RMSEA
	548/142	.844	.878	.109	.757	.701	.566	.131
e15↔e16	530/141	.849	.883	.110	.760	.700	.564	.129
e7↔e9	516/140	.853	.888	.110	.763	.698	.563	.127

4.2 Relations of elements

Figure 1 shows that there are some relations between the five elements. To comprehensive decision-making capability, information-communication capability is the most dependent construct, with the estimate value of 0.32. Then it is leading group command and resources allocation capability, while there is no relation between comprehensive decision-making and diseases control capability. To leading group command capability, the order of influence is information-communication, diseases control and resources allocation capability. To resources allocation and information-communication capability, the estimate value is 0.19. And resources allocation capability is negatively associated with diseases control capability. In addition, the estimate value between diseases control capability and information-communication capability is 0.48.

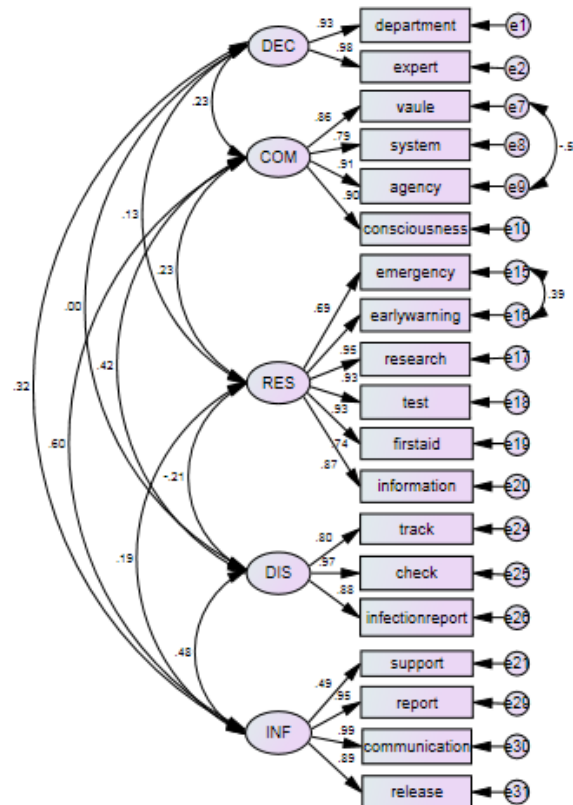

Figure 1 The Model of Confirmatory Factor Analysis

Note: DEC=comprehensive decision-making; COM=leading group command; RES=resources allocation; DIS=diseases control; INF=information-communication.

4.3 Key indices of elements

According to above analysis, the key indices of government emergency management capability of major public health paroxysmal incident in China are as follow, in descending order by factor loading: advice from the experts and departments in comprehensive decision-making capability; the agency and consciousness of coordination, leadership value and system in leading group command capability; the groups on the field of early warning, research, test, information report, first aid and emergency in resources allocation capability; morning check, infection report and tracking management in diseases control capability; communication, report and release of information, as well as resource support in information-communication capability.

4.4 Relations of measurement errors

The added path between e15 and e16, e7 and e9 has some implications. Training on groups of early warning and emergency is of great significance to the resources allocation capability building. The result shows the relation between early warning and emergency work, laying stress on their succession and intersection. Besides, leadership value is negatively associated with the coordination agency, which indicates if the government attaches importance to emergency management, the investment in specialized coordination agency as well as its workload will get relieved.

5 Conclusions

The study has several limitations, the most important of which is the sampling method would make the research result influenced by the sample size and public official's prejudice. Moreover, as the index of international cooperation capability failed to reach the statistical level, it was forced to be deleted, which should be taken into consideration.

This paper summarized five key elements of Chinese government emergency management capability of major public health paroxysmal incident from pertinent literatures, namely, comprehensive decision-making, leading group command, resources allocation, diseases control and information-communication capability, and analysed the relations of the elements. Furthermore, it got the indices of government emergency management capability by designing and verifying the GEMC scale empirically. The study contributes to the orientation of emergency management capability building in China. Future research will need to focus on the concrete suggestions to the government.

Abstract: With the questionnaire survey, this paper obtained 108 valid questionnaires and generalized 839 words representing the influencing factors of business model innovation, and then the words were classified into 45 keywords. Based on this classification, every keyword was encoded and the keyword network was formed. The method of social network analysis (SNA) and the software of Ucinet6 were used to draw the network diagrams of keywords, and got the value of network centrality including degree centrality, betweenness centrality and closeness centrality. Finally, the author got the key influencing factors of business model innovation.

Key words: Business model innovation; Network of keyword; Social network analysis

1 Introduction

Recently, the business environment is changing rapidly. And the sustainable competitive advantage is often derived from the business model innovation (Voelpel, Leibold & Tekie, 2004)^[1]. Research literatures also show that business model innovation has become the research focus of scholars who focus on strategic managements. The interest in business model innovation is growing (Aspara, Hietanen & Tikkanen, 2010; Zott, Amit & Massa, 2011)^[2,3].

But currently there is little study about the factors which effect the business model innovation. Most researchers believed that globalization, deregulation and technological change system (Casadesus-Masanell & Ricar, 2010)^[4], the growth of the Internet and e-commerce (Teece, 2010; Zott, Amit & Massa, 2011)^[5] are the main factors, but de Jong & Vermeulen (2005)^[6] pointed out that the influencing factors of innovation include five levels which are countries, industries, organizations, groups and individuals. However, there is lack of quantitative research about the influencing factors of business model innovation. This paper will explore the factors that affect business model innovation through questionnaires and social network analysis to provide a basis for future research of business model innovation.

2 Research and Design

2.1 Research Questionnaire

Since the questionnaire about the empirical research of business model innovation has not been found, we designed the questionnaire based on the research purpose. The research questionnaire obtains an open topic, "Which factors do you think influence business model innovation? (Please use words or sentences, fill in the following blank line)."

2.2 The Research Sample

We selected four chemical companies as the research sample. In order to improve the recovery rate of the questionnaire, we first communicated with relevant department managers of the four companies, and released the questionnaire after received the managers' consent. The time of the survey is from December 16 to 19, 2012.

2.3 Method

This study used the software of Ucinet6 and the method of social network analysis to study the network of keywords of business model innovation. Through the centrality analysis including degree centrality, betweenness centrality and closeness centrality, we can identify important keywords, determine the key influencing factors of the business model innovation and lay the foundation for future research.

3 Results

3.1 Keywords Statistics of the Influencing factors of Business Model Innovation

This study recovered 108 valid questionnaires; each questionnaire extracts some words, the number is from 3 to 19, and finally received a total of 839 influencing factors words of business model innovation with an average of 7.77 words per questionnaire. At last, we get 45 keywords by adjusting and classifying. The 10 highest frequency words were showed in Table 1.

Table 1 The 10 Highest Frequency Words of Influencing Factors of the Business Model Innovation

No.	Code	Keyword	Frequency	No.	Code	Keyword	Frequency
1	C52	organizational culture	114	6	C16	self-motivation	50
2	C11	innovation legitimacy	83	7	C38	staff thinking	34
3	C41	staff absorption capacity	77	8	C40	external environmental pressures	34
4	C27	employee entrepreneurship	56	9	C33	personality traits	33
5	C54	organizational resources	56	10	C37	market demand	26

According to Table 1, the influencing factors of business model innovation basically are divided into two categories. One category is the organizational-level factors including organizational culture, innovation legitimacy, organizational resources, external environmental pressures and market demand; the other one is staff-level factors including the staff absorption capacity, employee entrepreneurship, self-motivation, staff thinking and personality traits.

The descriptive statistics can only test the frequency of each keyword, but could not verify the relationship of these high frequency keywords with other words, and can not analyze the effect of these high-frequency words in the overall keywords system. However, the method of social network analysis can test the effect of these high-frequency words in the overall keywords system. So, we constructed a network diagram of all of these keywords in order to reveal and analyze deeply.

3.2 Keywords Network of Influencing Factors of Business Model Innovation

Figure 1 The Keywords Network of Influencing Factors of the Business Model Innovation

Firstly, coding the final 45 keywords and corresponds to the 839 words which were provided by 108 questionnaires. The keywords of each questionnaire constitute a small fully connected network, then 108 small networks connect into a large keyword network. The keywords network through the Netdraw in software Ucinet6 was drawn and showed in Figure 1.

The keyword network of the influencing factors of the business model innovation can determine the importance of each keyword by the analysis of degree centrality, betweenness centrality and

closeness centrality. Degree centrality is mostly used to measure the most important center of this group; and betweenness centrality is used to measure the ability of a keyword as the media (Luo Jiade, 2005)^[7]. According to the calculation of Ucinet6, the centrality of top ten keywords was showed in Table 2.

Table 2 Centrality of the Influence Factors of the Business Model Innovation Keywords Network(Top Ten)

Degree centrality			Betweenness centrality			Closeness centrality		
Coding	Keywords	Value	Coding	Keywords	Value	Coding	Keywords	Value
C52	organizational culture	100	C52	organizational culture	8.795	C52	organizational culture	100
C11	innovation legitimacy	90.909	C16	individual incentives	5.54	C11	innovation legitimacy	91.667
C16	individual incentives	86.364	C11	innovation legitimacy	5.005	C16	individual incentives	88
C41	employees' absorptive capacity	84.091	C41	employees' absorptive capacity	4.305	C41	employees' absorptive capacity	86.275
C54	organizational resources	84.091	C54	organizational resources	3.893	C54	organizational resources	86.275
C27	entrepreneurship	79.545	C27	entrepreneurship	2.285	C27	entrepreneurship	83.019
C32	enterprise strategy	75	C39	team cooperation	2.194	C39	team cooperation	80
C38	employees' thinking mode	75	C32	enterprise strategy	2.127	C32	enterprise strategy	80
C39	team cooperation	75	C33	Personality traits	1.834	C38	employees' thinking mode	80
C17	individual social capital	72.727	C38	employees' thinking mode	1.822	C33	personal characteristics	78.571

We can see from the Table 2 that, at the organizational level, the degree centrality values of “organizational culture”, “innovation legitimacy”, “organizational resources”, “corporate strategy” and “teamwork” are 100, 90.909, 84.091, 75 and 75; the betweenness centrality values are 8.795, 5.005, 3.893, 2.127 and 2.194; closeness centrality values are 100, 91.667, 86.275, 80 and 80. Centrality value is higher, which means these keywords are the important technical tool linking many research topics about influencing factors of the business model innovation.

We can also find from table 2 that, at the employee level, the degree centrality values of the “individual incentives”, “employees' absorptive capacity”, “entrepreneurship”, “employees' thinking mode”, “individual social capital” and “personal characteristics” are respectively 86.364, 84.091, 79.545, 75, 72.727 and 72.727; the betweenness centrality values are respectively 5.54, 4.305, 2.285, 1.822, 1.546 and 1.834; and the closeness centrality values are 88, 86.275, 83.019, 80, 78.571 and 78.571. The values are all high, and it means that the “individual incentives”, “employees' absorptive capacity”, “entrepreneurship”, “employees' thinking mode”, “individual social capital” and “personal characteristics” are in the core position of the keywords network, and they are the important technical tool linking many research topics about the influence factors of business model innovation.

4 Conclusion

This paper collects the influencing factors of business model innovation by designing the questionnaires. Based on word induction, keyword classification, encoding and network structure analysis, we obtained the front keywords which are organizational culture, innovation legitimacy, individual incentives, employees' absorptive capacity, organizational resources, entrepreneurship, enterprise strategy, employees' thinking mode, team cooperation, individual social capital and so on. These keywords can be divided into the level of organization (organizational culture, innovation legitimacy, organizational resources, enterprise strategy and team cooperation, etc.) and the level of employees (individual incentives, employees' absorptive capacity, entrepreneurship, employees' thinking mode, individual social capital and personal characteristics). The recognition of these factors is the important supplement of the research on business model innovation, and makes people know more about the factors of influencing the business model innovation.

In the practice, managers should focus on the multiple influencing factors of the level of organization and staff to promote the innovation of business model and to contribute to the development of enterprises. In future research, we not only need to further explore the influencing factors of business model innovation, but also need to test each factor's influence degree and mechanism so as to provide theoretical support for enterprise to carry on the business model innovation.

International Marketing: Innovative Strategies for Entering Foreign Market

Abdoulaye Oury Bah, Argelia Munoz Pahuamba

School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070

(E-mail: bahgio2008@hotmail.com, xkf@whut.edu.cn, argmuz@gmail.com)

Abstract: The current shift in the marketing strategy is working by international companies, nowadays, it is high-end rather than adaptive development that is being carried out by leading companies, and increasingly, other companies are finding themselves competing against or working with, new innovations, process and outcomes of globalization. Organization succeeds in a competitive marketplace over long run because they can create; do certain things their customer's value better than can their competitors. Strategy means planning and for me planning means getting ready to implement actions for our future, international marketing is a part of the process that keeping the benefit of international trade to the advanced sector at the top of the agenda and to keep its profile high and recognized. As the trend toward economic globalization increases, the internationalization of small and medium-sized enterprises (SMEs) has become an important topic. Research on the performance outcomes of foreign market entry strategies has been primarily considered from the perspective of the multinational corporations. However, a career in international marketing can be very challenging. Located far from their head offices, international marketing professionals have to make decentralized decisions, carry out different responsibilities, and deal with various risks. In fact they are frequently tasked to navigate political, economic, socio-cultural and technological conditions which they have never faced before.

Key words: International Competition; International Marketing; Strategies for Emerging Countries, Risks

1 Introduction

In recent years a number of economists have researched whether international trade has contributed to the ongoing rise in the U.S. relative price between more-skilled and less-skilled Labor. There is still no clear consensus, however, about how much international trade has mattered. Many people find this ambiguity difficult to reconcile with the large amount of anecdotal evidence that trade has been placing substantial "pressure" on labor markets. In this paper I look for pressure not in the prices for labor but rather in the elasticity's of demand for labor. I examine whether trade has been increasing firms' equilibrium own-price elasticity of demand for labor. In theory trade can change labor-demand elasticity's without changing labor prices. As will be discussed, trade can make labor demand more elastic in two main ways: by making output markets more competitive and by making domestic labor more substitutable with foreign factors. The global market has traditionally been the battlefield of large, multinational corporations (MNCs). However, the past 20 years has witnessed the evolution of a new global manufacturing environment, with firms of all sizes now competing globally in order to obtain new competitive advantages. Unfortunately, most global operational research has focused on the practices of MNCs and neglected the fact that small and medium sized enterprises (SMEs) and MNCs do not operate in similar ways. The global market has traditionally been the battlefield of large, multinational corporations (MNCs). However, the past 20 years has witnessed the evolution of a new global manufacturing environment, with firms of all sizes now competing globally in order to obtain new competitive advantages.

Unfortunately, most global operational research has focused on the practices of MNCs and neglected the fact that small and medium sized enterprises (SMEs) and MNCs do not operate in similar ways. Spurred by technological advances in transportation and communications, many strategists have used contingency theory to explain how an organization maximizes its alignment of strategy with its environment to achieve performance outcomes within a domestic strategy context ,the issue of strategic fit in an international context takes on additional complexities due to the problems of control and coordination, confounded by the actions of foreign market agents and the policies of foreign governments, particularly for SMEs. The theoretical precepts for a contingency model for SME international expansion therefore must consider the unique issues associated with resource commitment, as well as the relevant external factors associated with foreign markets. . . .

The Fair Trade movement seeks to transform international market relations, forging new

consumer/producer links based on trust, equity, and fairness. In the words of the major US Fair-Trade organization, “Our vision is nothing less than restructuring the relationship between producer and consumer—the trade inequalities between North and South”. Though the international trade in Fair Trade labeled products is quite young and represents only a minor share of the global market, this trade has grown dramatically in recent years...

2 Competing Internationally and Globally

As we know a company is international when just he selects one or few foreign market for his transaction either competing on a truly global scale comes later after a company established operation on several continents and is racing against rival willing to be a leadership. They opt to expand into foreign market cause that offers potential to increase them revenues, profits and long-term grown, sometimes to achieve lower costs and enhance the company competitiveness willing to sell more help and to capitalize on its core competencies and capabilities, to spread its business risk across a wider market base. Globalization is not a new phenomenon, it began in the late nineteenth century, but it slowed down during the period from the start of the First World War until the third quarter of the twentieth century. This slowdown can be attributed to the inward-looking policies pursued by a number of countries in order to protect their respective industries... however, the pace of globalization picked up rapidly during the fourth quarter of the twentieth century...

Managers must be conscious that markets, supplies, investors, locations, partners, and competitors can be anywhere in the world. Successful businesses will take advantage of opportunities wherever they are and will be prepared for downfalls. Successful managers, in this environment, need to understand the similarities and differences across national boundaries, in order to utilize the opportunities and deal with the potential downfalls. Essentially, globalization refers to growth of trade and investment, accompanied by the growth in international businesses, and the integration of economies around the world. The globalization concept is based on a number of relatively simple premises that I can mention as:

- Technological developments have increased the ease and speed of international communication and travel.
- Increased communication and travel have made the world smaller.
- A smaller world means that people are more aware of events outside of their home country, and are more likely to travel to other countries.
- Increased awareness and travel result in a better understanding of foreign opportunities.
- A better understanding of opportunities leads to increases in international trade and investment, and the number of businesses operating across national borders.
- These increases mean that the economies around the world are more closely integrated.

Managers must be conscious that markets, supplies, investors, locations, partners, and competitors can be anywhere in the world. Successful businesses will take advantage of opportunities wherever they are and manager in this environment, need to understand and look at the similarities and differences across national boundaries, in order to succeed. The globalization of business is easy to recognize in the spread of many brands and services throughout the world. For example, Japanese electronics and automobiles are common in Asia, Europe, and North America, while U.S. automobiles, entertainment, and financial services are also common in Asia, Europe, and North America.

Moreover, companies have become transnational or multinational—that is, they are based in one country but have operations in others. For example, Japan-based automaker Honda operates the largest single factory in the United States, while U.S. based Coca-Cola operates plants in other countries including France and Belgium with about 80 percent of that company's profits come from overseas sales. Unfortunately, this rapid growth was not without consequences the Seattle meetings of the World Trade Organization turned into a fiasco, with anti-globalization groups demonstrating against globalization on all fronts from animal rights to environmental concerns, poverty alleviation, and jobs for Americans.

In addition, the Asian Tigers suffered major economic setbacks in the late 1990s. In late 2002 Argentina's economy which had been one of the stars of the 1990s, crashed, when the country could no longer maintain its currency at par with the U.S. dollar. Further problems occurred in the Triad economies Japanese economy went into a severe period of recession and deflation in the late 1990s, and in 2001 both the European and the U.S. economies took a downward turn as well. In turn, the rest of the world was negatively affected by the economic situation in the Triad. The terrorist attacks in the United States in September, 2001, exacerbated this already negative economic situation. In developing appropriate global strategies, managers need to take the benefits and drawbacks of globalization into

account. A global strategy must be in the context of events around the globe, as well as those at home. International strategy is the continuous and comprehensive management technique designed to help companies operate and compete effectively across national boundaries.

Manager should perform some of these following processes to avoid troubles.

Study the political, economical, socio-cultural and technological situation of the foreign country. Also use strategies on segmentation, targeting and positioning the company, determining the international product life cycle at the same time branding the product in accordance with the country. Therefore should implement the marketing mix in accordance with the need of the foreign country by determining the price of the product on one hand set up the distribution system for the international trade and in the other hand study and follow the advertising standardization in the country. Some rudimentary aspects of international strategies mirror domestic strategies in that companies must determine what products or services to sell, where and how to sell them, where and how they will produce or provide them, and how they will compete with other companies in the industry in accordance with company goals. The development of international strategies entails attention to other details that seldom, if ever, come into play in the domestic market. These other areas of concern stem from cultural, geographic, and political differences. Consequently, while a company only has to develop a strategy taking into account known governmental regulations, one language (generally), and one currency in a domestic market, it must consider and plan for different levels and kinds of governmental regulation, multiple currencies, and several languages in the global market.

2.1 Overview of International Strategy Development

Generally, a company develops its international strategy by considering its overall strategy, which includes its operations at home and abroad. We can consider four aspects of strategy: scope of operations, resource allocation, competitive advantage, and synergy. The first component encompasses the geographic locations countries and regions of possible operations as well as possible markets or niches in various regions.

Since companies have limited resources and different regions offer different advantages, managers must select the markets that offer the company the optimal opportunities. The second component of the global strategy focuses on use of company resources so that a company can compete successfully in the chosen markets. This component of strategy planning also determines the relative importance of various company functions and bases the allocation of resources on the relative importance of each function. For instance, a company may decide to allocate its resources based on product lines or geographical locations.

2.2 Strategy–SWOT Analysis

SWOT is an abbreviation for **Strengths, Weaknesses, Opportunities and Threats**. SWOT analysis is very important and successful tool for a manager to help them auditing the overall strategic position of a business and its environment, more to take advantage over its rivals or competitors. Once the key strategic is set, issues have been identified, they can now feed into business objectives, particularly marketing objectives. SWOT analysis can be used in conjunction with other tools for audit and analysis, such as PEST analysis and PORTERS five-force analysis. It has been mentioned that is also a very popular tool for business to grow and marketing students should focus on it to have better understanding of the market and I believe it is quick and easy way to learn because help you to develop or expand your company.

2.2.1 The Key Distinction - Internal and External Issues

Strengths and weaknesses are internal factors. For example, strength could be your specialist marketing expertise. Indeed manager expertise in the major items of its portfolio almost is the key to the success of the products in the market. Expertise spans a wide range of graphic design, new media, advertising and digital marketing etc...

A weakness could be the lack of a new product or product innovation such kind of issues can affect the company benefit. Opportunities and threats are external factors. Let's say an opportunity could be a developing distribution channel such as the Internet, web distribution channel as the current scenario, a distribution

channel plays an important role in the smooth supply of the products and its customers satisfaction, or changing consumer lifestyles that potentially increase demand for a company's products. A threat could be a new competitor in an important existing market or a technological change that makes existing products potentially obsolete. It is worth pointing out that SWOT analysis can be very subjective - two people rarely come-up with the same version of a SWOT analysis even when given the same information about the same business and its environment. Accordingly, SWOT analysis is best used as a guide and not a prescription.

Adding and weighting criteria to each factor increases the validity of the analysis.

Table 1 SWOT Analysis

		Positive	Negative
		Strengths	Weakness
I N T E R N A L	Positive	<ul style="list-style-type: none"> • Technological Skills • Leading Brands • Distribution Channels • Costumer Loyalty/Relationship • Product Quality • Scale • Management 	<ul style="list-style-type: none"> • Absence of Important Skills • Weak Brands • Poor access to Distribution • Low Customer Retention • Unreliable Product/Services • Sub-Scale • Management
	Negative	<ul style="list-style-type: none"> • Changing Customers Tastes • Liberalization of geographic Market • Technological Advanced • Changes in government politics • Lower personal Taxes • Change in population age structure • New distribution channels 	<ul style="list-style-type: none"> • Changing Customers Tastes • Close a geographic Market • Technological Advanced • Changes in government politics • Tax increases • Changes in population age structure • New distribution channels
E X T E R N A L	Positive	<ul style="list-style-type: none"> • Changing Customers Tastes • Liberalization of geographic Market • Technological Advanced • Changes in government politics • Lower personal Taxes • Change in population age structure • New distribution channels 	<ul style="list-style-type: none"> • Changing Customers Tastes • Close a geographic Market • Technological Advanced • Changes in government politics • Tax increases • Changes in population age structure • New distribution channels
	Negative	<ul style="list-style-type: none"> • Changing Customers Tastes • Liberalization of geographic Market • Technological Advanced • Changes in government politics • Lower personal Taxes • Change in population age structure • New distribution channels 	<ul style="list-style-type: none"> • Changing Customers Tastes • Close a geographic Market • Technological Advanced • Changes in government politics • Tax increases • Changes in population age structure • New distribution channels

2.3 Competitive Advantage

The goal of much of business strategies is to achieve sustainable competitive advantage. Differences in wages rates, worker productivity, inflation rates, energy costs, tax rates, government regulations and the like create sizable variations in manufacturing costs from country to country. Michael Porter identified two basic types of competitive advantage: Cost Advantage and Differentiation Advantage, a competitive advantage exists when the firm is able to deliver the same benefits as competitors but lower costs (cost advantage) or, deliver benefits that exceed those of competing products (differentiation advantage) thus a competitive advantage enables the firm to create superior value to its customers and superior value to itself. The following diagram combines the resources-based and positioning views to illustrate the concept of competitive advantage:

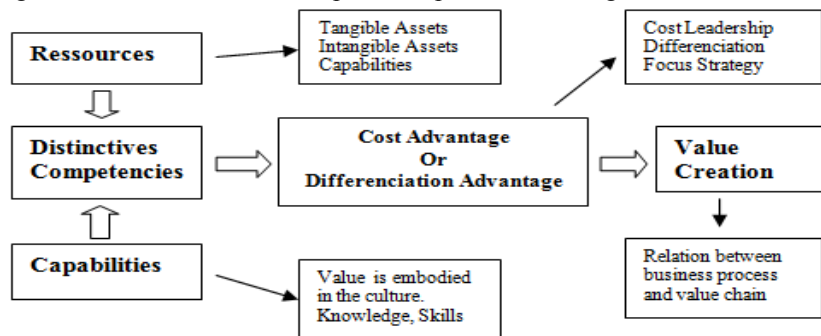

Figure 1 A Model of Competitive Advantage

2.3.1 Resources and Capabilities

According to the resources-based view, in order to develop a competitive advantage the firm has resources and capabilities that superior to those of its competitors. Without this superiority, the competitors simply could replicate what the firm was doing and any advantage quickly would disappear. Resources are the firm-specific assets useful for creating a cost or differentiation advantage and that few competitors can acquire easily. The following are some examples of such resources:

- ✓ Patents and trademarks
- ✓ Proprietary know-how
- ✓ Installed customer base
- ✓ Reputation of the firm
- ✓ Brand equity

2.3.2 Capabilities

Refer to the firm's ability to utilize its resources effectively. An example of a capability is the ability to bring a product to market faster than competitors. Such capabilities are embedded in the routines of the organization and are not easily documented as procedures and thus are difficult for competitors to replicate. The firm's resources and capabilities together form its distinctive competencies. These competencies enable innovation, efficiency, quality, and customer responsiveness, all of which can be leveraged to create a cost advantage or a differentiation advantage.

2.3.3 Cost Advantage and Differentiation Advantage

Competitive advantage is created by using resources and capabilities to achieve either a lower cost structure or a differentiated product. A firm positions itself in its industry through its choice of low cost or differentiation. This decision is a central component of the firm's competitive strategy. Another important decision is how broad or narrow a market segment to target. Porter formed a matrix using cost advantage, differentiation advantage, and a broad or narrow focus to identify a set of generics strategies that the firm can pursue to create and sustain a competitive advantage.

2.3.4 Value Creation

The firm creates value by performing a series of activities that Porter identified as the value chain. In addition to the firm's own value-creating activities, the firm operates in a *value system* of vertical activities including those of upstream suppliers and downstream channel members. To achieve a competitive advantage, the firm must perform one or more value creating activities in a way that creates more overall value than do competitors. Superior value is created through lower costs or superior benefits to the consumer (differentiation).

2.4 Build Company Competitive Advantage Based on Customers Value Delivery Strategy, Sustainable Marketing Systems

Sustainable marketing is a new concept put forward by Philip Kotler in his book *Rethinking Marketing: Sustainable Marketing Enterprise in Asia*. Sustainable marketing is a strategic conception. Its aim is to make three main stakeholders-consumer, employees and stockholders to get sustainable satisfaction. In the 2004, Philip Kotler put forward company sustainable marketing system in his latest composing, and made further interpretation of the sustainable marketing”.

The company sustainable marketing system is composed of three main strategic parts: strategy (S), tactics (T), and value (V), which are described as strategic business triangle. This system comprises three dimensions:

- Strategy-how to win the strategic share,
- Tactics-how to win the market share, and
- Value-how to win the sensation share.

The sustainable marketing system is dynamic process of identifying customer value, offering customer value and communicating customer value from outside.

Firstly, the company determines STV strategy through market segmentation, selecting target market and making market position. In this way, the company could confirm which products to offer and which target consumer to serve, as well as which customer value to satisfy. Then the company should determine the differentiated tactics aiming at target market, and supply customer value through marketing mix and selling. Meanwhile, the company could try to build up brand image, improve service quality, and provide additional service to communicate customer value. Therefore, we could use company sustainable marketing system--STV triangle to build company competitive advantage based on customer value delivery strategy, shown as figure:

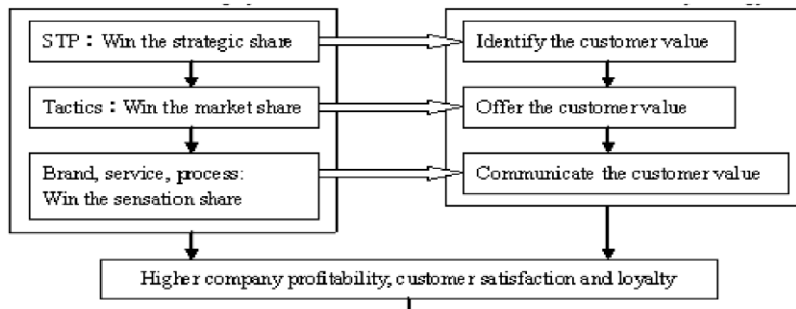

Figure 2 The framework of Company Competitive Advantage Based on Customers Value Delivery Strategy, Sustainable Marketing Systems.

3 International marketing Strategies That Fit Emerging Markets

Companies racing for global leadership have to consider competing in emerging markets like China, Brazil, India, Indonesia, Mexico and South Africa countries where the business risks are considerable but where the opportunities for growth are huge (example: Coca Cola has focused its marketing effort in China and India on making drinks attractive to status seeking young people in urbanized areas). It's no easy task to identify strategies for entering new international markets or to decide which countries to do business with. Many firms simply go with what they know and fall far short of their goals. Part of the problem is that emerging markets have "institutional voids": They lack specialized intermediaries, regulatory systems, and contract-enforcing methods. These gaps have made it difficult for multinationals to succeed in developing nations; thus, many companies have resisted investing there. That may be a mistake. If Western companies don't come up with good strategies for engaging with emerging markets, they are unlikely to remain competitive. Many firms choose their markets and strategies for the wrong reasons, relying on everything from senior managers' gut feelings to the behaviors of rivals. Corporations also depend on composite indexes for help making decisions. But these analyses can be misleading; they don't account for vital information about the soft infrastructures in developing nations. A better approach is to understand institutional variations between countries. The best way to do this is by using the five contexts framework. The five contexts are a country's political and social systems, its degree of openness, its product markets, its labor markets, and its capital markets. By asking a series of questions that pertain to each of the five areas, executives can map the institutional contexts of any nation. When companies match their strategies to each country's contexts, they can take advantage of a location's unique strengths. But first firms should weigh the benefits against the costs. If they find that the risks of adaptation are too great, they should try to change the contexts in which they operate or simply stay away. How does the experience of the emerging markets compare with that of the developed markets? In the developed markets, sector influences are more pronounced and they appear earlier in the data. This can be seen when you are entering the market, where, and overlay with developing markets it is not easy things to deal with.

Is It All Due to tech Stocks? An increased role of sector influences can be rationalized as the result of greater integration across markets by investors who have an increasingly global outlook.

4 Risks to Competing in Foreign Markets

The foreign exchange business is by natural risky, because it deals primarily in risk—measuring it, pricing it, accepting it when appropriate, and managing it. The success of a bank or other institution trading in the foreign exchange market depends critically on how well it assesses, prices, and manages risk, and on its ability to limit losses from particular transactions and to keep its overall exposure controlled. Broadly speaking, the risks in trading foreign exchange are the same as those in marketing other financial products. These risks can be categorized and subdivided in any number of ways, depending on the particular focus desired and the degree of detail sought. Here, the focus is on two of the basic categories of risk—market risk and credit risk (including settlement risk and sovereign risk)—as they apply to foreign exchange trading. Note is also taken of some other important risks in foreign exchange trading—liquidity risk, legal risk, and operational risk. The risk of an investment's value changing due to changes in currency exchange rates is one fact for internationalization.

However the risk that an investor will have to close out a long or short position in a foreign currency at a loss due to an adverse movement in exchange rates. This also known as "currency risk" or "exchange-rate risk". This risk usually affects businesses that export and/or import, but it can also affect investors making international investments. For example, if money must be converted to another currency to make a certain investment, then any changes in the currency exchange rate will cause that investment's value to either decrease or increase when the investment is sold and converted back into the original currency

5 Conclusion

After examining the prospective markets in this manner, managers are ready to evaluate the advantages and disadvantages of each potential market. One way of doing so is the determination of costs, advantages, and disadvantages of each prospective market. The costs of each market include direct costs and opportunity costs. Growth through foreign market expansion has become an increasingly popular strategy, as previously closed foreign markets open and as economies around the world globalize. Spurred by technological advances in transportation and communications many

strategists have used contingency theory to explain how an organization maximizes its alignment of strategy with its environment to achieve performance outcomes within a domestic strategy context. There can be various ways through which a business organization can achieve success in the market, but all those ways can be comprised into as above, then it can be rightly said that it revolves specifically around three parties or more; the triangular linkages or the relationship between these three parties (company, customers and competitors) determine the success and failure of business organization. Supply Chain Managers can provide considerable value to their companies by understanding the customers' delivery requirements. A very powerful tool for understanding these requirements is account segmentation. A company can use account segmentation to identify market segments Such as Acute & Chronic therapy market.

Abstract: Informal finance serves as an important complement to the finance system, which can provide private, small and medium-sized enterprises the necessary financial support as well as promote agriculture development while bringing enormous financial risks that cannot be ignored. For the timely discovery and risk prevention, considering its theoretical value and practical significance, this paper sets up an informal finance risk early warning index system by applying early warning system construction principles, integration with Analytical Hierarchy Process and Experts Scoring Method. In addition, this paper chooses data of Hubei Province of China as the empirical analysis object.

Key words: Informal Finance Risk; Early Warning Index System; Analytical Hierarchy Process; Weight

1 Introduction

In retrospect of the past 30 years, China's informal finance has grown from small to big, from surplus capital to industrial capital and financial capital. Take Wenzhou as an example, among the overall capital of SME (small and medium-sized enterprises), there are only 24% coming from the state-owned commercial financial institutions; and the other 76% are coming from informal finance. Till 2012, the scale of informal finance in Wenzhou has reached 500 billion RMB. On one hand, informal capital is the beneficial supplement of formal finance, gradually becoming the important financial income of SME, rural areas and farmer, which will further boost the local economy. However, lacking the supervisions of laws and regulations, risk control measures of civil finance is hard to be involved into the supervision of formal finance, which will further cause many problems during its development, and even affect the stability of the society.

Scholars from home and abroad have conducted abundant research in theory and practice. Hangzhou Branch of Central Bank of China research group (2008) has illustrated the innate risk, regarding different informal finance activities. Li Wei (2007), Pan An'e (2008), designed risk evaluation index system from different viewpoint^{[1][2]}. Ni Jian (2009) has come up with the control measures for informal finance^[3]. Looking back to the research home and abroad, there are few comprehensive analyses for the informal finance risk warning regarding risk levels, risk warning index, and risk prevention. Therefore, to strengthen the research of informal finance risk early warning control and management and to find and prevent warning position, are of great significance in theory and practice, for promoting a virtuous circle of national economy and informal finance.

2 Methods of Constructing the Risk Early Warning Index System

2.1 Analytical Hierarchy Processes

Analytical Hierarchy Process (AHP) was proposed by Professor Thomas L.Saaty of Pittsburgh University in the nineteen seventies which provided a Multi-objective decision analysis method from both qualitative and quantitative aspects. According to the dominant relation, it decomposes the complex problem into a number of factors, these factors will be further decomposed, then line up on the basis of hierarchy of objectives, criteria, indexes, forming an Orderly hierarchical structure with multi-objective and multi-level. To calculate the relative importance of each factor by comparing in pairs, to evaluate the judgment matrix in a comprehensive way, finally there can be a total order arranged by the importance of each factor. Since informal financial risk early warning index system contains four first-level indicators, 13 secondary-level indicators and 30 third-level indicators which are obvious multi-level structure, this paper adopts AHP to modeling.

2.2 Expert Scoring Method

Expert Scoring Method: First consult the related experts anonymously; after the comprehensive

* This paper is supported by “the Fundamental Research Funds for the Central Universities” (2012-IB-070) and Wenzhou Science and Technology Bureau.2013R2:2013R7

and objective summary, process, analysis and conclusion of most experts' experience and subjective judgment, make a reasonable estimate for those large number of factors which is difficult to make quantitative analysis in technique method; after several rounds of consultation, feedback and adjustment, analyze the data value index and value realization degree. Since the method need brainstorming, which can give full play to the collective wisdom of experts, to avoid subjectivity and one-sidedness, this paper selects the method for scoring the various early warning indicators, which were quantitatively analyzed.

3 The Construction of Informal Finance Risk Early Warning Index System

3.1 Construction Principles

Informal finance risk early warning index system should obey the following principles: a. The principle of combination of Comprehensiveness and Representativeness Principle. b. The principle of combination of Scientific and Operability Principle. c. The principle of combination of Adaptability and Complementarities Principle. d. The principle of combination of Sensitivity and Vigilance Principle. The subtle changes in the chosen index should reflect the situation of informal finance risk in time so as to adopt the related countermeasures to prevent the risk.

3.2 The selection of indicators and weighting

Table 1 Informal Finance Risk Early Warning Index System

	First-Level Indicator	Second-Level Indicator	Third-Level Indicator	Informal Financial Risk position				
				Level I (scores 0)	Level II (scores 1)	Level III (scores 2)	Level IV (scores 3)	
Informal Financial Risk Early Warning Index System B	B ₁ External Economic Environment Indicators (5.58)	B ₁₁ Macroeconomic Conditions (3.12)	B ₁₁₁ GDP Growth Rate (1.57)	>12	(8,12]	(4,8]	≤4	
			B ₁₁₂ Inflation Rate (0.94)	≤3	(3,6]	(6,9]	>9	
			B ₁₁₃ Real Estate Investment Growth Rate(0.38)	≤20	(20,30]	(30,40]	>40	
			B ₁₁₄ Unemployment Rate (0.23)	≤4	(4,6]	(6,8]	>8	
		B ₁₂ Government Regulatory Capacity(0.68)	B ₁₂₁ Fiscal Revenue to GDP Ratio (0.45)	>24	(20,25]	(15,20]	≤15	
			B ₁₂₂ Expenditure to GDP Ratio (0.23)	≤40	(40,45]	(45,50]	>50	
		B ₁₃ Business Conditions (1.78)	B ₁₃₁ Return on Assets (1.34)	>2	(1,2]	(0.5,1]	≤0.5	
			B ₁₃₂ Enterprise Loss Rate (0.44)	≤15	(15,20]	(20,25]	>25	
		B ₂ Risk of Informal Financial Institutions in Supervised System (53.79)	B ₂₁ Capital Adequacy (4.38)	B ₂₁₁ Capital Adequacy Ratio (2.92)	>12	(8,12]	(4,8]	≤4
				B ₂₁₂ Core Capital Adequacy Ratio (1.46)	>5	(3,5]	(2,3]	≤2
	B ₂₂ Asset Quality (25.50)		B ₂₂₁ NPL ratio (11.90)	≤5	(5,10]	(10,15]	>15	
			B ₂₂₂ Non-performing Loan Ratio (7.08)	≤1	(1,2]	(2,3]	>3	
			B ₂₂₃ Overdue Loans Ratio (4.09)	≤4	(4,8]	(8,12]	>12	
			B ₂₂₄ Top Ten Customers Loan Ratio (2.43)	≤40	(40,50]	(50,60]	>60	
	B ₂₃ Profitability (8.75)		B ₂₃₁ Interest Rate Receivable(2.92)	≤5	(5,15]	(15,25]	>25	
			B ₂₃₂ Return On Capital (5.83)	>12	(8,12]	(4,8]	≤4	
	B ₂₄ Liquidity (15.16)		B ₂₄₁ Cash Reserve Ratio (10.11)	>7	(5,7]	(3,5]	≤3	
			B ₂₄₂ Loan-deposit Ratio (5.05)	≤65	(65,75]	(75,85]	>85	
	B ₃ Risk of Pawn (24.95)	B ₃₁ Profitability (4.07)	B ₃₁₁ Pawn Capital Margin (2.71)	>10	(5,10]	(0,5]	≤0	
			B ₃₁₂ Synthetic Cost Rate (1.36)	>4	(3.5,4]	(3,3.5]	≤3	
B ₃₂ Liquidity (7.41)		B ₃₂₁ Mortgage Rate (5.56)	≤60	(60,70]	(70,80]	>80		
		B ₃₂₂ Forfeited Realizations (1.85)	>95	(80,95]	(65,80]	≤65		
B ₃₃ Capital Security (13.46)		B ₃₃₁ Forfeited Rate (8.97)	≤5	(5,15]	(15,25]	>25		
		B ₃₃₂ Discount Rate (4.49)	≤50	(50,75]	(70,80]	>80		

B ₄ Risk of Guarantee agencies (15.68)	B ₄₁ Profitability (1.91)	B ₄₁₁ Main Operation Margins (1.27)	>30	(15,30]	(0,15]	≤0
		B ₄₁₂ Asset-liability ratio (0.64)	≤75	(75,85]	(85,95]	>95
	B ₄₂ Credit Risk (5.01)	B ₄₂₁ Guarantee Reserve Adequacy Ratio (3.76)	>25	(10,25]	(0,10]	≤0
		B ₄₂₂ Non-performing Asset Ratio (1.25)	≤1	(1,10]	(10,20]	>20
	B ₄₃ Encumbered Assets Condition (8.77)	B ₄₃₁ Compensatory Loss Rate (2.92)	≤5	(5,10]	(10,15]	>15
		B ₄₃₂ Compensatory Rate Guarantee (5.85)	≤3	(3,4]	(4,5]	>5

(Note: The values in parentheses signify the indicators' weight relative to total target.)

Practice shows that there are two kinds of the forms of informal finance institutions. One is the institutions in supervised system; the other is out of being controlled by the supervised system. Among them, informal finance institutions in supervised system including rural credit cooperatives, urban credit cooperatives and rural cooperative foundations, institutions outside the supervised system contains private lending, underground banks, RCAs, pawn shops and guarantee agencies. This paper chooses pawn shops and guarantee agencies as representatives to study the risk of institutions outside the supervised system for data easily obtained.

Applying the multi-level indicator system and "The New Basel Capital Accord", this paper calculates each indicator's critical value by referring to widely recognized early warning values and principles of financial risk early warning interval criteria. And based on these, this paper divides all the indicators into four levels demonstrating. Each level with different colors and points illustrated as follows: level I means security scores 0, with "Blue Light", while level II stands for basic security scores 1, with "Green light". Besides, level III represents warning scores 2, with "Yellow light". level IV signifies dangerous scores 3, with "Red light". Therefore, the informal finance risk assessment system has formed (as shown in Table 1).

3.3 To weight each indicator

3.3.1 To construct judgment matrix

After considering the different importance of each indicator in the first-level of informal financial risk early warning index system, using a 1-9 ratio scale method to assign its importance by AHP and Experts Scoring Method, the result is shown in Table 2.

Table 2 The Assignment of level I indicators' importance

First Level Indicators	B ₁	B ₂	B ₃	B ₄	W
External Economic Environment B ₁	1	1/6	1/5	1/4	5.58%
Risk of Informal Financial Institutions in Supervised System B ₂	6	1	3	4	53.79%
Risk of Pawn B ₃	5	1/3	1	2	24.95%
Risk of Guarantee institutions B ₄	4	1/4	1/2	1	15.68%

Therefore, obtaining a judgment matrix of indicators' importance

$$A = \begin{bmatrix} 1 & 1/6 & 1/5 & 1/4 \\ 6 & 1 & 3 & 4 \\ 5 & 1/3 & 1 & 2 \\ 4 & 1/4 & 1/2 & 1 \end{bmatrix}$$

3.3.2 To calculate the weight of each indicator at same level.

(1) Multiply the elements of each row in matrix A.

Obtained: $B_1=1/120, B_2=72, B_3=10/3, B_4=1/2$.

(2) Calculate n-th Root of B_i , order $C_i = \sqrt[n]{B_i}$ (i=1,2,3,...,n)

Obtained: $C_1=0.3021, C_2=2.9130, C_3=1.3512, C_4=0.8490$.

(3) Normalize Vector $C=(C_1, C_2, C_3, \dots)^T$, order $W_i = \frac{C_i}{\sum C_i}$ (i=1,2,3,...,n).

$W = (W_1, W_2, W_3, \dots)^T$, W_i is the weight of each indicator.

Obtained: $W_1=0.0558$, $W_2=0.5379$, $W_3=0.2495$, $W_4=0.1568$ (see table 2).

3.3.3 Consistency test

After calculating the weight of each indicator, it does not mean that the process of setting target weight has finished. Since effected by strong subjective sense of human beings, the assignment of judgment matrix need to be verified its consistency, as to evaluate the reliability.

(1) To calculate Consistency Index CI, $CI = \frac{\lambda_{max} - n}{n - 1}$. λ_{max} is the maximum Eigen values of

the judgment matrix. N is the order. The larger value CI the greater deviation from consistency. In contrast, the value of CI is smaller(close to 0)CI smaller value (close to 0), indicating that the better degree of consistency. By using the Mat lab software to calculate data, we obtain:

$$\lambda_{max} = 4.1389, CI=0.0463.$$

(2) To calculate Consistency ratio CR, $CR=CI/RI$. For the value RI, you can direct look-up table 3. When $n = 1,2$, $RI = 0$. For $n \geq 3$, if $CR < 0.1$, accept consistency, that means judgment matrix consistency test passed; if $CR \geq 0.1$, then appropriate adjustments to the corresponding judgment matrix.

Table 3 Average Random Consistency Index Value

n	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
RI	0	0	0.58	0.90	1.12	1.24	1.32	1.41	1.45	1.49	1.51	1.54	1.56	1.58	1.59

In this case, $n=4$, look-up table 3 shows, $RI = 0.90$, $CR = CI / RI = 0.0514 < 0.1$, pass the consistency test.

By applying expert scoring method, we make assignment of the importance of the level II and level III indicators of the informal financial risk early warning index system, in accordance with its affiliation to the higher indicators. After using the same method validation mentioned above, which proved that all the indicators have better consistency, we finally obtained the weight of indicators at all levels.

3.3.4 To calculate the indicators' weight relative to the target.

After weighting each indicator at the same level by Analytical Hierarchy Process, we may calculate the indicator relative to the total weight of the target.

$$\text{Equ: } W_{ijk} = W_{B_i} \times W_{B_j} \times W_{B_{jk}} \tag{1}$$

$$W_{ij} = W_{B_i} \times W_{B_j} \tag{2}$$

Where W_{ijk} is the total weight of the target of indicator B_{ijk} . W_{ij} is the total weight of the target of indicator B_{ij} . W_{B_i} is the weight of indicator B_i in the first level, W_{B_j} is the weight of indicator B_j in the second level, $W_{B_{jk}}$ is the weight of indicator B_{jk} in the third level. According to these steps, we can obtain all the indicators' total weight of the target. (As shown Table 1).

3.4 Comprehensive warning model

To calculate the risk of the comprehensive evaluation value Z, according to the following formula.

$$\text{Equ: } Y_{ij} = \frac{\sum X_{ijk} \times W_{ijk}}{\sum W_{ijk}} \tag{3}$$

$$Y_i = \frac{\sum Y_{ij} \times W_{ij}}{\sum W_{ij}} \tag{4}$$

$$Z = \sum_{i=1}^n W_i Y_i, (i=1,2,3,4; j=1,2,\dots,n; k=1,2,3,\dots, n) \tag{5}$$

W_{ijk} is the total weight of the target of indicator B_{ijk} . X_{ijk} is the score of the indicator B_{ijk} . By Experts Scoring Method. Y_{ij} is the score of the indicator B_{ij} in the second level. Y_i is the score of the indicator B_i in the first level. Z is the comprehensive evaluation value.

When calculating Z, look up Table 1 to determine the overall operation situation of informal financial institutions and express warning instructions.

4 Empirical Analysis of Informal Financial Risk Warning System

4.1 Establishing original database of the warning index of financial risk

To regulate, evaluate and early warning risks, this paper adopts external economic environment data of Hubei Province of China from the year 2007 to 2011 to test the results (shown table 4).

Table 4 The original data of the external economic environment index of Hubei province of China(%)

Indicator	2007	2008	2009	2010	2011
GDP Growth Rate	14.60	13.40	13.50	14.80	13.80
Inflation Rate	4.80	6.30	-0.40	2.90	5.80
Indicator	2007	2008	2009	2010	2011
Real Estate Investment Growth Rate	28.10	23.30	34.50	34.80	27.70
Unemployment Rate	4.21	4.20	4.21	4.18	4.10
Fiscal Revenue to GDP Ratio	6.33	6.27	6.29	6.33	7.78
Expenditure to GDP Ratio	13.65	14.57	16.13	15.67	16.37
Return on Assets	5.35	5.89	5.68	7.99	8.06
Enterprise Loss Rate	16.89	14.33	13.02	10.62	8.18

Data resource: the Office for Hubei statistics and data from other related regulators.

4.2 To score the indicators

According to the data above and corresponding with index critical value in Table 1, the scores of each indicator can be achieved. Take data of 2011 as an example.

Firstly, scoring the third-level indicators:

- [1] GDP Growth Rate= 13.80%, fall into the first interval of the warning zone, scores 0.
- [2] Inflation Rate=5.80%, fall into the second interval of the warning zone, score 1.
- [3] Real Estate Investment Growth Rate= 27.7%, fall into the second interval of the warning zone, scores 1.
- [4] Unemployment Rate=4.10%, fall into the second interval of the warning zone, scores 1.
- [5] Fiscal Revenue to GDP Ratio=7.78%, fall into the fourth interval of the warning zone, scores 3.
- [6] Expenditure to GDP Ratio=16.37%, fall into the first interval of the warning zone, scores 0.
- [7] Return on Assets=8.06%, fall into the first interval of the warning zone, scores 0.
- [8] Enterprise Loss Rate=8.18%, fall into the first interval of the warning zone, scores 0.

Then calculate the comprehensive assessment of the external economic environment condition:

- (1) The calculation of third-level indicator system:

$$\text{Macroeconomic Conditions}=(0 \times 1.57\%+1 \times 0.94\%+1 \times 0.38\%+1 \times 0.23\%) \div 3.12\%=0.50$$

$$\text{Government Regulatory Capacity}=(1 \times 0.45\%+3 \times 0.23\%) \div 0.68\%=1.68$$

$$\text{Business conditions}=(8.06\% \times 1.34\%+91.82\% \times 0.44\%) \div 1.78\%=0$$

- (2) The calculation of External Economic Environment Indicators

$$\text{External Economic Environment Indicators}=(0.50 \times 3.12\%+1.68 \times 0.68\%+0 \times 1.78\%) \div 5.58\%=0.48$$

Finally, correspond the composite scores with table 1, it shows that the informal financial external economic environment of Hubei province of China in 2011 is generally in a state of financial security.

Similarly, we can calculate the scores of other sub-systems and the composite value of the informal financial risk system of Hubei province of China, then evaluate its safety.

5 Conclusion

To detect and prevent informal finance risk in time, this paper constructs an informal finance risk index system featuring relatively comprehensiveness, simplicity but effectiveness and also collects the data of Hubei province of China as an example to analyze, as to show practicality of the system. This system can contribute to proving theoretical supports for regulators' decision-making as well as effectively reducing and avoiding the risk of a regional financial crisis. For the purpose of more accuracy evaluation of warning system, all the indicators need to gradually perfect in the future.

Acknowledgment

The author is grateful to "the Fundamental Research Funds for the Central Universities" and

Wenzhou Science and Technology Bureau for their financial supports for the paper. And the author wishes to express their most sincere appreciation to those who give help and suggestion for the paper.

Diversity and Innovation: Empowering Women Fosters Innovation

Yuko Hayashi

Graduate School of Innovation and Technology Management, Yamaguchi University, Yamaguchi, Japan,
755-8611

(E-mail: hayashiy@yamaguchi-u.ac.jp)

Abstract: Women’s participation in labor market is required to utilize diverse variety of talent. In Japan, females are not participating in the labor market yet, especially in policy/decision making positions although the legislation has progressed slowly. There are many potentials that might achieve a remarkable improvement in terms of innovation growth and productivity by incorporating the female labor force in the Japanese economy. Women’s active participation to economy is one of the pivotal economic growth strategies of Japanese government in 2013. The government is aiming to attain the target of 30% of women’s participation in policy/decision making process by year 2020. However, only two categories attained that target number, pharmacists and member of the councils for national government. In order to win the objective in seven years, more positive actions will be needed. This paper explores why females are needed in the Japanese labor market, how extent women improve corporate performance and economy, and how women’s diversity fosters product innovation and process innovation. Materials used for analysis are related government papers, books, and journals. Some interviews with business executives were conducted.

Key words: Diversity; Women’s matter; Innovation; Positive action; Gender gap,

1 Introduction

World economy moves quickly and market changed day by day. To survive through the bustling world, diverse human resource should be utilized appropriately as a human capital portfolio. The then U.S. Secretary of States Hillary Clinton said at APEC Women and the Economy Summit 2011 “Unlocking the potential of women by narrowing the gender gap could lead to a 14-percent rise in per capita incomes by the year 2020.” Christine Lagarde, director of the international Monetary Fund, delivered the speech during the annual meetings of the IMF & the World Bank Group held in Tokyo 2012, “Women could save Japan’s economy if more of them went to work.” Women’s participation is essential in order to boost economy in a short term and a long term.

2 Why Does Economy Need Women?

2.1 A declining birth rate and work force

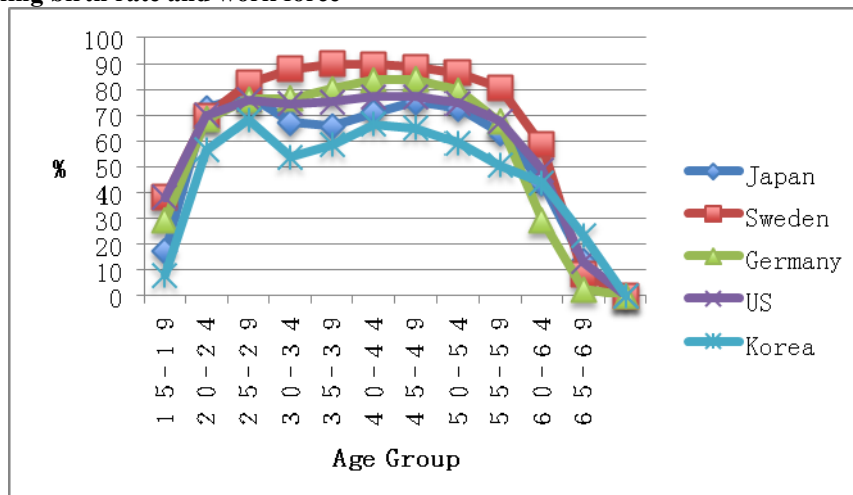

Figure 1 Female Work Force Participation Rate by Countries

(Source: Statistics Bureau, Ministry of Internal Affairs and Communication (2011) and ILO LABORSTA)

Exhibit 1 shows female work force participation rate by some OECD countries. Japanese women’s work force participation rate in age group from 25 to 54 years old ranks 22nd among 30 OECD countries.

In Japan and Korea, in age group from 30-34 years old, the female work force participation rate declines sharply. In this age group, women tend to give birth after marriage and retire their jobs and raise their children at home. After children are raised up, mothers go back to jobs or try to find new jobs so that a job participation rate increases again around age 40-49 though it is difficult to take good occupations as before they retired. Consequently, the line graph forms M-shaped. This tendency cannot be seen in other countries below. In Sweden, during the age group 30-34, female work force participation rate increase in contrast.

Recently, Japan’s work force decline about a million people per year because of a low birth rate and retiring the baby boom generation. Total population is declining since 2011 due to the diminishing birthrate so that demographic structure in Japan changes to the ageing society. 2.6 people in working generation are supporting the one elderly person now. Declining work force might give a good chance for non-working women. As about 3.42million female from 25-to 49 years old want to have jobs,^[1] they have a possibility to compensate for the reduction of the labor, if they could.

Among the OECD countries, there are some countries, such as Italy, Korea, and Japan that have a low birth rate. Those countries tend to face the serious concerns of falling birth rate and rapid aging population coming with demographic changes.

Consequently, some worry when female goes to work and does not stay home, birth rate might diminish more. However, as Exhibit 2 shows, it is not true in OECD countries.

Relations between women’s employment rate and birth rate have not been studied profoundly. There are some hypothesis why a birth rate does not decline when women have jobs in developed countries. First, when a husband and wife work together, total income of the family increases so that they can have more stable finance plan for raising children.

Figure 2 Women’s Employment Rate and Birth Rate in OECD Countries
(source: Calculated with OECD statistics data 2010)

At the same time, when the one loses a job, the other partner support family expense. Second, a country which is able to provide substantial public supports for working women, could provide supports for raising childrens so that working woman would have more children.

2.2 Some economic indexes show women’s contribution to improving business performance

Countries and companies should deploy people effectively in order to obtain a sustainable competitiveness. However, it is not certain that how extent the profit would expand when the employment of women is expanded. A report of Goldmansachs says “in many countries where there is already a high proportion of educated women who are not working, the potential economic boost from employing more of them does not necessarily come at a significant cost.Greater female employment has direct implications for household disposable income and savings, which have a trickle-down effect in terms of higher spend on education and health.”^[2]

Exhibit 3 shows when the women’s employment rate goes up, the GDP per capita goes up in OECD countries. When a woman works, total income per family increases and disposable income increases as well.

Figure 3 Women's Employment Rate and GDP
(source: calucrated with OECD statistics data 2010)

Mckinsey's report "Women's matter 2010" suggested the top-quartile companies in terms of share of women in executive committees from 2007 to 2009 show higher financial performance of this top-quartile companies with all-male executive committees. As for return on equity, the top-quartile group with companies exceeds by 41 percent the group with zero women. In terms of earnings before interest and taxes, the top-quartile companies exceeds by 56 percent.

Exhibit 4 Companies with a Higher Proportion of Women in Their Executive Committees have Better Financial Performance^[3]

- Companies in the top quartile for the women representation in executive committee vs. sector
- Companies with Zero Women in Executive committee in that specific sector

Source: Women's Matter 2010

TSE (Tokyo Stock Exchange) and METI (the Ministry of Economy, Trade and Industry) tackled jointly to designate enterprises that are encouraging women's success in the workplace as "Nadeshiko-brand" in February, 2013. 17 companies was selected as a Nadeshiko-brand. ^[4]

Figure 5 Performance of the Nadeshiko Brand in Tokyo Stock Excnage

Note: the excess rate of return was calculated by subtracting the rate of return on the TOPIX index of 72 stocks on the basis of the April 1, 2009 in the same period.

Source: Japan Cabinet Office Kyodo-Sankaku Number 56 April-May 2013 pp10

The Exhibit shows the performance of the top three enterprises (in total 72 stocks) that have high Nadeshiko index among 33 each industry in Tokyo Stock Exchange. "Nadeshiko index" is designated in order to promote the visibility to what extent companies would encourage women to play active role in the workplace. Compared with the TOPIX (:Tokyo Stock Price Index), high Nadesiko index enterprises tend to exceeds the performance of the TOPIX and their excess return expands almost consistently year by year.

Through the Nadeshiko Brand and index, METI is aiming to accelerate the efforts of listed companies for encouraging women's success showing that the investors who are interested in improvement of corporate value over medium to long term would like to invest the value added companies that promoting women's success.

The analysis shows the more gender diverse companies tend to have a higher performance than the companies with less gender diversity.

2.3 diversity triggers some innovation

Companies should utilize the variety of gender, age, ethnic, social and carriers so that they would obtain competitive advantages, foster innovation, minimize risks, and acquire productivity improvement.

In Japan, women are not participating in the labor market well or management positions in workplaces so there is a significant potential that should be pulled out.

By including in the female labor force, the Japanese economy might achieve a remarkable improvement in terms of innovation growth and productivity.

Japan, however, ranked at the bottom of the table of women senior management among 40 economies with just 7 percent occupied by the women according to the report of Grant Thornton.^[5] . Global average of women as percentage of senior management is 24 percent. China is the highest at 51 percent followed by Poland at 48 percent and Latvia 43 percent. The report says countries at top of the table for women in senior management such as China, Latvia, Vietnam, Thailand and the Philippines have high GDP growth for 2012 between 7-8 percent while the bottom eight countries for women in senior management such as Japan, the UK with 19 percent and the USA with 20 percent are also experiencing low levels of growth, with GDP in Japan (1.9%), the UK (-0.1%) and the USA (2.2%) in 2012. In terms of the company's board, G7 countries have just 16 percent of female board members while 26 percent occupied by women in the BRIC economies and 38 percent in the Baltic states.

According to "Equal Employment Opportunity Survey (Equity Research) of Japanese Ministry of Health, Labour and Welfare " in 2011, among the Japanese companies with 10 or more regular employees, 78.7% of the companies have more than one divisions with no or less than 10% female managers. 48.9% of the companies answered as a reason to no/less female managers "at the moment, there are no women with the knowledge, experience and ability of judgment." In addition, 16.3% answered "No one meets the enough job tenure", 15.0% answered "Women tend to have low seniority and retire before they become managers".^[7]

Figure 6 Equal Employment Opportunity Survey

Source: Equal Employment Opportunity Survey, Japanese Ministry of Health, Labour and Welfare, 2011

Why diversity is necessary to the current economy is stemming from the techno-paradigm shift.

Gibbons suggested in his thesis production of knowledge shifted from “Mode1” to “Mode2”

“The old paradigm of scientific discovery (‘Mode 1’) – characterized by the hegemony of theoretical or, at any rate, experimental science; by an internally-driven taxonomy of disciplines; and by the autonomy of scientists and their host institutions, the universities – was being superseded by a new paradigm of knowledge production (‘Mode 2’), which was socially distributed, application-oriented, trans-disciplinary, and subject to multiple accountabilities.”^[6]

Kodama indicated that innovation patterns shifted from technology breakthrough to technology fusion. “Recent innovations in mechatronics and optoelectronics make it more appropriate to view innovation as the fusion of different type of technology rather than as a series of technology breakthroughs.”^[8] The techno-paradigm shift requires different abilities from the past. Not only specialized knowledge but also interdisciplinary one will be needed to achieve innovations. Ways of thinking has been changed from Homo to Hetero, from uniform and standardized to diversity.

Valleys of Death or Darwinian Seas is a metaphor which separates research from product development. How to interlock two separated areas where asymmetry of information exists would be important for innovation.^[9] Among the institutional gaps and variety of stakeholders, management of diversity plays a pivotal role as well.

There are some examples of successful patterns of innovation incorporating management of diversity especially for women. Some product innovation and process innovation have been created by women from the female point of views.

Examples of Product Innovation

- Nissan motor company, after made an alliance with Renault S.A. of France, the diversity inside the company has increased ethnically and genderly. The company has promoted diversity management as a business imperative. For instance, one manager becomes in charge of two sections that interests conflict each other. To manage two different contradict business activities, managers would be trained for management of diversity. The company succeeded in developing new car incorporating female’s idea. Domestic market is shrinking because of low birth rate and aging society. 74 percent of wives are the decision maker to buy somethings in the family. When you decide to buy a car, 60 percent of decision makers are women, which is more than half. So, the company formed a woman team for to car product development in order to reflect women needs to the design.

For instance, Nissan Note adopted the rear seat doors open to 85 degrees so that it is easy to get in and out with children or children in a buggy. You can carry children very quickly and safely. This car achieved the best sales for five consecutive months sales among gasoline cars.^[10]

- A Japanese electronics maker, Toshiba corp. started a female managers development program. Ms Fukushima, the member of the inaugural class, was successful in the development of world first glasses free 3D televisions. The company is developing consumer electronics series from female point of views. For instance, capability of refrigerators in retention of vegetables’ freshness has been improved well.

- Kirin holdings company involved female staffs in liquor product planning. The staffs hit an idea of non-alcoholic beer women could drink during pregnancy and breast-feeding. Thanks to meet the needs of women, new markets has been successfully developed and replaced the shrinking beer market.^[11]

Process innovation

- Tenhiko launched web site for steel sales for overseas making use of female employees who have good English language skills but working as clerical work before. International sales have increased through the internet and a casual type of web design attracted people. The company’s amokestack image have changed and people regarded the company as a place that is easy to work. A number of applicants for the company has increased for both men and women from 20 applicants before web site started to exceeded 2000 in fiscal year 2011.

- Start Today Co.Ltd., the company running internet fashion and clothing mall called “Zozotown”, introduced 6-hour work (9:00 to 15:00) for all employees and it contributed to increase a productivity 25% year-on-year improvement. Women employees raising up their children came to feel easy to pick them up at nurseries. Some employees go and visit shops to search something in fashion after work which contribute to their business marketing knowledge.

Women engineers who came back to work after childcare leave organized “Customer Care Group”. During the daytime, they visited customers to understand market needs with sensitivities.

This activity contributed to the business development after that.

3 Conclusions, implications and actions

The analysis suggested that any companies and enterprises with gender diversity show higher performance than those with less diversity. It is said that diversity might boost economy and many economic indexes show them. Companies in Japan are providing many cases that female employees contributed to product innovation and process innovation. So that incorporating gender diversity might contribute to create innovation. However, rate of the Japanese women who are in the labor market is still low in Japan comparing to world average and rate of the women who are in senior management is still low as well and glass ceilings remain almost all the countries although the number of the female management is increasing in total. In order to enhance the gender diversity, many policy should be accelerated including positive actions.

Research on Passenger Satisfaction and Behavioral Intention under the Situation of Flight Delay Based on SEM

Wang Zheng¹, Liu Xiaoping²

1 School of Marxism, Wuhan University of Technology, Wuhan, P.R.China, 430070

2 School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070

(E-mail: liuxiaoping_0301@163.com, 43177305@qq.com)

Abstract: Based on the survey data from passenger satisfaction questionnaire in the context of flight delay and using structural equation model, the factors impacting passenger satisfaction and their relations are investigated in the paper. The results show that: the travelers expect directly impact their satisfaction. The passengers want to affect the passenger behavior indirectly by the mediating variable called the passenger satisfaction. At the same time the expectation will also affect the passenger satisfaction through the mediating variable named perceived value and ultimately affect the passenger behavior. In this paper a service management model aiming to improve passenger satisfaction is proposed, including that the airlines and airports should take measures to meet the travelers' expectation, raise the service quality comprehensively to improve the passenger satisfaction and so on, to reduce and avoid the irrational behavior of travelers.

Key words: SEM; Flight Delay; Factor Analysis; Passenger Satisfaction

1 Introduction

With the development of Chinese economy, the civil aviation industry of China has seen rapid development. According to statistics, the number of registered civil aviation planes in China exceeded 600 in 2003, with the number of airplanes being about 1000. By the end of 2009, the total number of registered civil aviation airplanes increased to 1400, and the number of scheduled airlines was 1.5 times as many as it previously had been^[1]. Because of the increase of people's livelihood and the acceleration of living rhythm civil aviation has become one of the main transportation methods owing to its comfort ability and fast speed. While civil aviation is in its fast development phase, flight delay often occurs due to the lack of transportation capacity of airline companies and other reasons such as weather, traffic control in the air, air safety and so on. "Survey report of Air service consumer in 2011" which was released by China Consumers Association shows that complaints on airline service have become the biggest service complaints industry. 76.5% of consumers encounter delays which show that flight delay is widespread. Flight delay causes mismatch of transport service resources, and affect travel plans of passengers, service quality of air transport and enterprise image of air transport. Because of flight delay information lack of transparency and sharing, no emergency disposal and timely guidance scheme which lead to passenger group incident and bring negative effects to aviation safety. This article begins with the degree of satisfaction of passengers and conducts demonstrative research, in the end comes up with responsive suggestions.

2 Reference Overview

Through looking up in domestic and foreign references, it is found that researches on emergent conflicts between passengers and airline companies caused by flight delay are rarely seen abroad. This is mainly because although some European and American countries have different ways to regulate compensation for flight delay, most of them doesn't have compensation regulations for passengers. They only regulate in transportation conditions that airline companies should provide communication, transportation, food and accommodation and so on for passengers if a flight is delayed. Few of them specifically require compensation for flight delay, emergent conflicts between passengers and airline companies caused by flight delay have been hardly reported. Since 2000 emergent conflicts have gradually increased in China. Many researchers have conducted a number of studies, which have gained plenty of results. Lu Rong (2006) argued from the policy aspect that since China Civil Aviation Bureau released "Instruction for economic compensation caused by flight delay" in 2004, mass emergencies under circumstances of flight delay had gradually increased, and even become more drastic in recent years. The main reason lay in the discrepancy of compensation standards^[2]. Li Xiong believed that after flights were delayed, airports, air control authorities and airline companies have not properly exchanged related information, and that led to dissatisfaction of passengers, which further evolved to irrational

behavior such as beating related staff, sabotaging security facilities, jamming security entrances and soon^[3]. Zhou Haibin (2010) studied passengers' service remedy after flight delay. These literatures have too many descriptive studies which are lack of empirical studies on the influencing factors' relationship of passengers' satisfaction^[4]. Although Zhang Li (2006)^[5] studied the relationships of passengers' satisfaction and behaviors, he studied passengers' behavior intentions from passenger s' psychology and from negative emotions and he didn't study passengers' expectations, passengers' perception and passengers' perceived value. This study adopt structural equation model to analyze the causal relationship between passengers' satisfaction and behavior intention, according to actual situation of passengers' behavior when flight delay, from the related theory, the design of questionnaire, the construction of passengers' satisfaction and behavior intention of causal model.

3 Research Methods

Linear correlation analysis shows statistical relationship between two random variables which are in equal status and have no differentiation on independent and dependent variables^[6]. Although the traditional regression defined independent and dependent variables in models which can only provide direct effect between variables and cannot display possible indirect effects, appear the analysis results of overall and individual index negative which were unable to interpret because the reason of co linearity. Structural equation model is a causal method which constructs latent variable estimation and testing of latent variable which contains not only the latent variables which cannot be measured directly, but also the dominant variables which can be measured directly, which can handle multiple dependent variables, and compare and evaluate different theory model^[7,8]. Structural Equation Model is a method that establishes estimation of latent variables and proves the cause-effect relation between latent variables. It consists of Measurement Model and Structural Model. As for the relation between latent variables and exogenous variables, namely is called as Measurement Model.

4 Designation of Scales, Correlation of Data and Statistics of Samples

In order to secure the reliability of the questionnaires, we firstly had an interview with related people, and identified the main part of the questionnaires as well as the specific questions. Then we sent the questionnaires to experts in related fields, and asked them to give some suggestions, after that we modified the questionnaires based on feedbacks; secondly we had a test on the questionnaires among a small circle, further modifying the questionnaires; at last we came to a relation chart which describes the relation between satisfaction of passengers and their behavioral intention in case of flight delay. The whole chart consists of five sub-charts, and they are service expectation, service conception, conceptive value, satisfaction of passengers and passenger behavior respectively. The questionnaires adopted Linker five-point scale, 1 signals very unsatisfied, 2 refers to not very satisfied, 3 refers to normal, 4 refers to relatively satisfied and 5 refers to very satisfied. In this survey 220 questionnaires have been sent out, from which 183 questionnaires have been effectively returned, the rate of effective return is 83.18%.

It can be seen that the ratio is about 1:1 in terms of the gender of interviewees, educational level of them is above college degree, their age is about 40; 61.8% of them encountered flight delay occasionally, 21.7% of them often encountered flight delay. As a whole, the samples surveyed have universality and representativeness, and the results of the survey have strong reliability and persuasion.

5. Empirical Analysis

5.1 Exploratory Factor Analysis

We have used SPSS16.0 to analyze all 15 factors. Validity reliability analysis shows that Cronbach's alpha value is 0.806, indicates that the scale with good reliability. Each subscale reliability: perception value, passengers' behaviors, service perception, passengers' satisfaction, service expectation, Cronbach's alpha= 0.835, 0.793, 0.751, 0.938 and 0.829, all more than 0.70 and meet the requirements, and correlation coefficient of each item and latent variable is relatively high. Therefore, the scale has good reliability and consistency. Due to the latent variable measurement has good reliability which need expand further exploratory factor analysis. Exploratory factor analysis find out mainly degree of correlation^[9] which affect numbers of observed variable factor, each factor and observed variables. Using SPSS16.0 analyze all of 15 factors. From the results of the statistics we know KMO value is 0.844, the value of KMO and Bartlett's Test is 1573, so the sample data have passed test. This indicates that it is suitable for factor analysis. We use the Maximum Likelihood method as a factor extraction method and select the maximum variance rotation Varian method to obtain clearer factor solutions using the

variance maximization orthogonal rotation, Using Maximum Likelihood method as extracting method, we extract those shared factors whose factor loadings are bigger than 0.5 through Varian. After Several rounds of iterative principal component factor analysis, we find out that there are 5 eigenvalue that are bigger than 1, accumulative contribution rated has reached 85.46%. This indicates that the remained 15 variables can be explained through these 5 shared factors (passenger perception value, passenger behavioral intention, passenger service perception, satisfaction of passenger and passenger expectation respectively). Therefore the structural design of the variables in the questionnaire is reasonable.

5.2 Model fitting

While undergoing structural model fit, we must take into account the sample is less than 500, estimated using Generalized Least Squares (GLS) will get better results^[10], and the fitting indicators are shown in Table 1. Figure 1 is the initial path graph on passengers’ satisfaction when flights delay and behavior intention structural equation model.

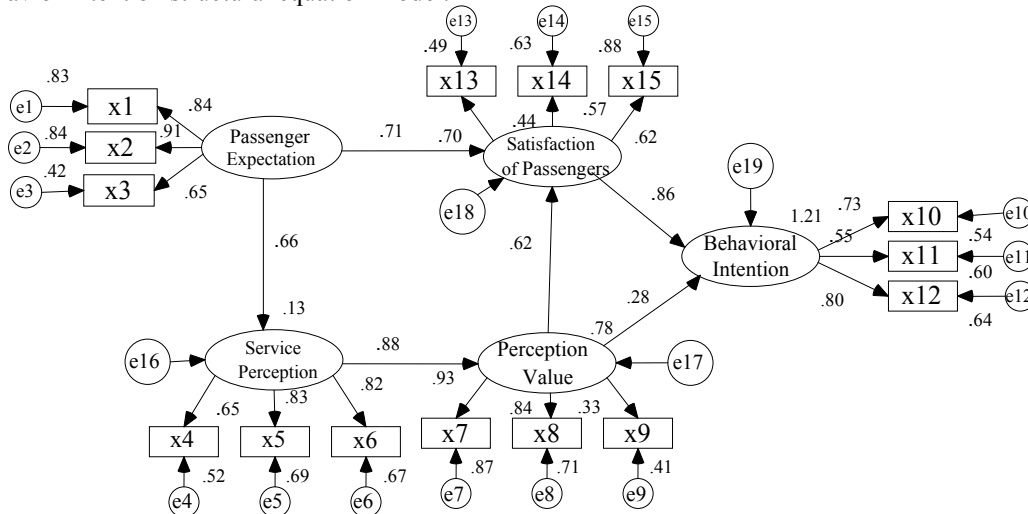

Figure 1 Flight Delays Initial Path Diagram of the Structural Equation Model

Table 1 The Parameter Values of the Initial Model Fitting Indicators

Indicator	chi-square	df	χ^2/df	GFI	AGFI	SRMR	RMSEA	CFI
Result	313	84	3.73	0.840	0.772	0.06	0.112	0.653

Exploratory Factor Analysis:We have used SPSS16.0 to analyze all 15 factors. From the results of the statistics we know KMO value is 0.844, the value of KMO and Bartlett’s Test is 1573, so the sample data have passed test. This indicates that it is suitable for factor analysis. We use the Maximum Likelihood method as a factor extraction method and select the maximum variance rotation Varian method to obtain clearer factor solutions using the variance maximization orthogonal rotation, Using Maximum Likelihood method as extracting method, we extract those shared factors whose factor loadings are bigger than 0.5 through Varian. After Several rounds of iterative principal component factor analysis, we find out that there are 5 eigenvalue that are bigger than 1, accumulative contribution rated has reached 85.46%. This indicates that the remained 15 variables can be explained through these 5 shared factors (passenger perception value, passenger behavioral intention, passenger service perception, satisfaction of passenger and passenger expectation respectively). Therefore the structural design of the variables in the questionnaire is reasonable.

Model modification:The further modified exponential model correction use Maximum Likelihood estimation method. Results of the model estimated parameters shows in Table 2. The modified model is shown in Figure 1.

Table 2 The Modified Parameter Values of the Initial Model Fitting Indicators

Indicator	chi-square	df	chi-square /df	GFI	AGFI	SRMR	RMSEA	CFI
Result	100.145	78	1.23	0.845	0.914	0.042	0.023	0.834

Based on the results of the assessment from the relevant fit index, the revised model chi-square statistic value is 100.145, df is 78, the chi-square / DF = 1.23 <3, indicating a better model fit. RMSEA 0.023 <0.05; GFI is 0.845, and the relative fitting index CFI of 0.834. The modified model indicators have reached the acceptable range, better fitting the structural equation model.

5 Conclusions

We have the following conclusions: (1) through factor analysis we get 5 shared factors: passenger behavior factor, service awareness factor, passenger satisfaction factor, service expectations. (2) We confirmed that visitors expect not only a direct impact on passenger satisfaction and passenger satisfaction through the mediating variables indirectly affect the behavior of passengers, but also find that the expectations of travelers will affect travelers perceived value and perceived value affect passenger satisfaction through the mediating variables ultimately affect the behavior of visitors, service perception perceived value and passenger satisfaction ultimately affect the behavior of visitors through the mediating variables.

According to the conclusions of this study, we propose service management model to improve passenger satisfaction. On one hand, traveler expectation indirectly affects passenger behavior through the mediating variable passenger satisfaction, after flight delays, airlines and airports should adopt management model that is consistent with travelers expect service. The civil aviation passengers select civil aviation as travel transport due to the improvement of living standards and a decline in ticket prices, different travelers face the same kind of service failure, and the intended purpose may be significantly different. For example, when flight delays, some travelers hope to get free tickets or discounts and other compensation, other travelers hope the airline can contact other flights to leave as soon as possible. For the different expectations of different travelers, airlines should treat differently. On other hand, airlines and airports want to improve all-round quality of service in order to improve passenger satisfaction. For example, provide human services in the transfer flight, waiting and flight delays. Due to the special nature of the civil aviation, flight delays are inevitable, it is necessary to establish the emergency response mechanism to refine service.

The Construction of Quality Management System of Commissioned Audit in Higher Education Institutions' Construction Projects

Zhou Yuan

Audit Office of Wuhan University of Technology, Wuhan, P.R.China, 430070

(E-mail: hbzhouyuan@126.com)

Abstract: Commissioned audit in higher education institutions' construction projects has become a main form of project audit, so as to realize specialization, socialization and refinement. But there still exists the problem on the assurance of audit quality. Based on the agency theory, this paper proposes the concept of the whole process management and constructs a quality management system of project commissioned audit in the process of early, middle and later phase of management, which covers the selection of agent, the design of optimal incentive contract, interim regulation and the afterwards evaluation.

Key words: Construction projects; Quality management; Commissioned audit; Agency

I Introduction

With the development of higher education in China, higher education institutions increased the investment in infrastructure construction. In order to save construction funds, standardize management, prevent corruption, the construction audit as an extension of the Internal Audit has developed rapidly. The report of university internal audit qualification audit issued is lack of engineering qualification, cannot meet the audit requirements of construction projects. To resolve this contradiction, university construction projects commissioned audit emerged. Chinese Ministry of Education issued "the Opinions on Strengthening the Whole Process of Auditing on Standardized Construction Project" on January 3, 2008, which officially includes the commissioned audit for university construction projects by using of the university audit approach. Social audit in construction projects is implemented by means of entrusting the construction project audit services to the engineering cost consulting companies and other institutions, which has become the university's general audit mode.

The university construction project audit provides the fresh blood for traditional internal audit, so as to realizing specialization, socialization and refinement of the construction project auditing. The driving force of social audit institutions entrusted with auditing is to make profit. From the university's standpoint, commissioned audit is facing a major problem of strengthening audit quality control and management to ensure the qualities of audits for university construction projects.

As to the current audit market of commissioned Chinese construction projects, engineering cost consulting companies and other social auditing institutions varies greatly. As the qualification requirement for practitioners is not high, who employed different levels of expertise, so it is difficult to ensure the quality of the audit commission. Construction projects commissioned audit was commissioned by the typical agency relationship, and exists the problems of information asymmetry and moral hazard; the immaturity of construction projects commissioned audit market, lack of credibility of the system of monitoring and surveillance, and so on. At present, the research on construction project commissioned audit quality control, is mostly discussed in the special aspect. For example, Zhu Feng (2007) studied the incentive contract arrangements and external oversight mechanisms on unique features, the inherent limitations and the role of both the law and the internal mechanism, which plays an important role in promoting audit quality and auditor independence^[1]; Ren Liang (2008) analyzed the interactive relationship between audit parties based on the game theory, and provided the countermeasures of the fraud audit quality control^[2].

Through in-depth study and practice, the author believes that construction management and control of project commissioned audit quality during the whole process of commissioned audit formed a system. Based on this point of view, under the early, middle, late management context of construction project commissioned audit, the author uses some idea of the principal-agent theory and game theory, and try to build construction projects commissioned audit system.

2 The Reference of Principal-Agent Theory

Principal-agent theory is the one of the main theory of institutional economics contract. The main research agency relationship refers to one or more actors designate, hires some actors servicing for them, while the latter must be granted the right decision, and according to the quantity and quality of services the corresponding reward is provided to pay under an express or implied contract. The one who authorizes is the principal, who is authorized is the agent.

Agency relationship is originated in the existence of "professional". "Professional" may occur a relationship that the agent may take the action because of the relative advantage. The modern sense of agency concept was first proposed by Ross: "If the parties, in which an agent acting on behalf of the interests of the principal party to exercise certain decision-making powers, then the agency relationship may formed." Unlike the traditional principal-agent theory from the perspective of microeconomics, analyzing the agency relationship in enterprises and between different enterprises, which explains some of the organizational phenomenon, and the general microeconomics construction projects commissioned audits are typically commissioned - - agent relationship, which involves two principals- the principal (university) and agents (fiduciary audit unit). Since the existence of specialization, compared with principal, agent has more relatively professional advantage in the exercise of agency business on behalf of the principal duties of the audit.

Agency relationship is a contractual relationship, and the contractual relationship is built on the premise of asymmetric information. In the process of project audit, audit unit entrusted has a more comprehensive grasp of the audit of the whole project, with more information and control, however, as the principal, higher education institutions has incomplete information, which means they need to take more risks. According to the principal-agent theory, for asymmetric information of both sides, and the different target in the project, the audited entity entrusted makes decisions following the principle of maximizing their own interests that may harm the interests of higher education institutions. As to the audit of the business project, discreditable behavior audit unit entrusted mainly lies in following several aspects: (a) the irresponsible and inefficient audit process. (b) fraud in audit process, instead of rigorous practice. (c) more worse thing is that the entrusted and the audit of the audited entity conspired to deceive the delegator to reach the purpose of making profit. In dealing with these risks, the establishment of an effective monitoring mechanism is particularly important.

Principal-agent relationship cannot avoid supervision. In fact, with the asymmetric information, the principal level of understanding of the agent's information can be selected by the principal himself. For example, by hiring supervisor or spending more time and energy, the principal may get more information about the agent to some extent. Thereby, it is necessary to strengthen incentives and supervision of agents. However, the acquisition of information will cost, so the client is facing problem of selecting the optimal supervision[3].

The classical economists thought marginal productivity depends on the worker's wages. But the development of the economists found that, in developing countries, the relationship between the two appears to be just the opposite: marginal productivity depends on the wage. And this phenomenon also exists in the developed countries. Solow(1979) and Shapiro and Stiglitz(1984) regarded higher wages as incentive approach to prevent laziness. When companies can not fully monitor the behavior of workers, wages become an opportunity cost of a lazy worker who is identified and dismissed. The higher wages, the greater opportunity cost. Therefore, higher wages help to reduce the tendency of workers' laziness. On the other hand, as to discussing the supervision problems in incentive wage model, we found that the higher the marginal productivity of agents, the higher the marginal revenue brought by supervision, and the higher principal motivation to supervision; The higher the marginal cost of the agent's effort, the lower supply of the given stimulus efforts under, and the lower of observing the behavior of the given information agents under the variance optimal incentive to monitor, the lower the marginal revenue, naturally, the principal supervision enthusiasm is lower; In addition, the more difficult supervision, the higher marginal cost, and supervision of the principal motivation is also lower..

3 The Choice of Agent

3.1 Adequate market research

The market of current construction project audit is basically controlled by the commissioning party audit, there are many cost consulting company, project manage companies and units with engineering audit qualifications. Enterprises compete fiercely with various means to contract business. Some reduced costs, some proposed to reduce audit time, and some contacted higher education institutions'

audit department through a variety of channels with the hope of providing commercial rebates. How to select best fiduciary audit unit fair, merit while limiting the risk of internal audit department, is becoming a problem that the university construction projects commissioned audit should face. As the saying goes, “seeing is believing”, the choice of agents should be based on sufficient investigations and studies, with a clear awareness of the proposed participation in competitive agent.

3.2 Bidding option

Selecting an agent bidding is necessary for an open, fair and just competition. Bidding determines the finalists units and establishes agent qualification library. Constructing project commissioned audit was commissioned by the service class, the price is an important factor in competition, but not the decisive factor, so it can take the qualification of storage, classification alternatives. The project cost consulting unit library is established through bidding. In the bidding process, technical standards are mainly focused on appraisal agencies, corporate reputation, performance, registered professional personnel, quality management system, financial condition, etc. All construction projects audit work shall be borne by the intermediary staff in the library. According to the scale of audited project, small projects commissioned are decided by the rotation, medium-sized projects by lottery number, large projects by fully understanding of advisory body’s cost of the qualification, credit status, results, business expertise and operational personnel composition, etc. Inviting reputable audit intermediary bank, and capable engineers of the Commission to participate in the bidding, means taking two finite invitations for public bidding in order to choose the best cost consulting company. Such ways are shown in the following table:

Table 1

Commissioned audit project amount	Entrustment
Below 2 million yuan	Rotation
2 million yuan to 5 million yuan	Determined by lottery
Above 5 million yuan	Secondary bidding

4 The Optimal Incentive Contract Design

According to principal-agent theory, in the environment of interests’ conflict and asymmetric information, the client should design the optimal contract incentive agent. The construction project implements audit entrusted audit contract according to the benefits of contract pay standard received from client. In modern economic activities, economic leverage should be the core of the optimal contract incentive agent, namely the pay standards.

When information is asymmetry, agent of income with the likelihood ratio varies, so the reasonable must fully embody the incentives of the agency contract, find appropriate likelihood ratio. Construction project commissioned audit the likelihood the ShenJian rate. Set ShenJian rate for B, are:

$$(1) B = S \text{ (amount) submitted} - D/S \text{ (authorized amount)}$$

ShenJian rate B can be viewed; its value can measure agent’s ability and working effort. Contract for construction project commissioned audit standards should be associated with ShenJian rate B [4]. Set the amount to be paid F settlement entrust audit contract, we can get pay with incentive factor model:

$$(2) F = B * b + M$$

Type: b for incentive factor (fixed or interval), and each additional unit increase in unit B, F b embodies the incentive role of agent. M for fixed payment, only related to the project scale and should change with engineering scale, authorized amount D reflects the engineering scale, namely, $M = f(D)$. Make M starting values for, a corresponding to the D value of D, when $0 < D \leq D_0$ or less when $M = a$; When $D > D_0$, M should be with the increase of D. The author believes that through practice D's positive contribution in the M should decline, diminishing ln function can be used to describe this relationship. (1) can be formulated as:

$$(3) F = B + a * B = 1 + (\ln - \ln D) D > D (D)$$

Type: According to the regional actual situation, b, a, d values should be, generally speaking, in 4% to 6% advisable, b d according to the requirement of the public bidding for 2 million yuan, is a value of ten thousand yuan(0.5 0.8).

Values of a and b, should reflect the cost of agents. And agent cost can neither be estimated beforehand, nor observed accurately afterwards. But as a general rule, engineers with high level can conduct a high quality audit, so the pay will also be higher accordingly, i.e. the

agent cost will be corresponding one, d, b should also be high correspondingly only for reasonable values.

5 Tracking and Monitoring

First, conduct the management under the principle of the program contract. Audit commission contract is the foundation of university construction project audit work. The rights and obligations are regulated by audit contract, so the responsibility is born by higher education institutions and the audit units, and is mainly based for final submission of audit results and audit fees. Special provisions in the contract must make it clear that who is responsible for audit, who is the trial cost engineers, what are audit schedule requirements, auditing and audit quality issues punitive measures proposed after the audit recommendations.

Secondly, combine the work content and delegate fees with quantitative management. Provincial price administration departments have developed a construction cost consulting services fee standards. Such as the Hubei Provincial Price Bureau in 2000 document No. 81 provides a standard for construction of the first audit-related fees, and changed in 2011 document No. 23. According to the specific implementation scope and its corresponding work content of the commissioned audit on the construction project, it should be paid one by one

Again, the special person is involved in supervision and management. Determine the specific involvement of internal audit staff to track the entire delegate audit work. Remand the whole process of quality control from the data, which transferred to the process management and coordination, report re-examination. Selected internal audit staff should handover the written project settlement information to advisory body first. At the same time, introduce the general situation of the construction project and project management, and put forward some problems in the engineering settlement audit; accomplish the supervision, inspection and control in the process of work. On the one hand oversight the schedule time according to the contract; on the other hand to check audit working papers irregularly and supervise the quality and quantity to complete its audit of the project. Questions raised by the audited entity entrusted, answered by the internal audit department staff contact the school site personnel infrastructure management, on-site person in charge of the construction unit representatives to the audit department. Ensure that all key aspects of internal audit were participated by universities' staff, to fully understand the situation and prevent the audited entity entrusted contact closely with the audited entity, and help to maintain interests of the school.

6 Regulatory Discipline

At the same time, strengthen government supervision. Such as national audit institutions audit periodically checks each dispatch various social audit advisory report issued by the agency. And regard the sampling results as the evaluation of social audit institution which can be continued to engage in construction projects based on project audits, or should be punished by penalties in accordance with sampling results. Increase government oversight force.

7 Conclusions

After the audit for large construction projects, the audit unit will handover outcome document. The internal audit department will evaluate the project, such as: the professional ability of engineer, the audit team's work attitude of the audit units, cooperation, audit time, communication and coordination ability, the reducing rate; The following measures can be taken: if failed to complete the audit of the quality requirements of the contract audit content, they should no longer be engaged in auditing business entrusted for 2 years; and if causing some economic loss to the university or universities, they should also be investigated due to their respective responsibilities.

Establish institutional repositories annual appraisal system. At the end of each year, the university organized internal related units to make a special audit assessment evaluation for the consulting audit company. According to survey results at the end of the year, the poor assessment units will be eliminated, then the secondary invite bidding units will be decided. If social intermediary organizations in the assessment are determined to be ineligible, they shall not be entrusted to engage in audit operations for 3 years. Those who violate the state laws and regulations, professional ethics, principle of avoidance, or have fraud, collusion, or tell secrets and other major violations, or obtain commissioned audit by the business through improper means, as well as have other problems spotted by departments in afterwards audit inspection, causing loss to the school and having adverse effects, will not allowed to entrust their

business in auditing, and will be notified to relevant authorities.

The quality of construction project audit can only be ensured by constructing the model, the construction of commission audit system, global management, effective supervision and coordination .

Employee Motivation and Satisfaction in Niger: An Application of the Job Characteristics Model

NABA Boukari Moctar, Luo Fan

School of Management, Wuhan University of Technology, Wuhan, P.R. China, 430070

(Email: mocnaba@yahoo.fr, Sailluof@126.com)

Abstract: The study examined the role of job dimension in determining the motivating potential score of the employees and compared the motivation of different sectors in Niger and also compared Niger employee's motivation and other place employee's motivation level. A sample of 120 employees of 3 sectors in Niger was surveyed using the job diagnostic survey and the scores were compared with the normative data established by Oldham, Hackman and Stepina using nine job families. The study revealed that the job dimensions highly influenced the motivating potential score. The study also revealed the presence of significant differences between the sectors and between Niger companies and Oldham, Hackman and Stepina normative data.

Key words: Motivation; Job characteristics model; Core job dimensions; motivating potential score.

1 Introduction

Employee motivation is one of the key variables that provide systematic opportunity for an organization success in all areas of its operation. Noteworthy is the fact that no matter how sophisticated an organization is (i.e. high degree of automation) it requires the services of human labor, therefore it is the human labor that serves as a locomotive engine for the attainment of organizational objectives. It is on record that organizations that perform excellently in the competitive market are those who have highly motivated staff; hence the ability of an organization to excel and perform well depends squarely on how it designed its motivational strategy.

This paper attempts to evaluates employee motivation in Niger through applying job characteristics model, Most studies on motivation were conducted in advanced countries with notable exception of the few, therefore this study will contribute to the stream of literature by focusing on small country with less managerial expertise. Three notable sectors namely; banking, telecommunications and mining industry were examined and the findings indicate high motivation potential score for the telecommunication sector followed by the banking sector and mining sector the last.

The rest of the paper is structured as follows; section 2 presents Hackman and Oldham theory, which describes job characteristics that promotes high performance. Similarly, this section presents motivating potential score (MPS) which serves as a basis of comparison between the sectors and even departments, section 3 presents methodology, section 4 presents the empirical results, while section 5 concludes the paper.

2 Presentation of the Theory and the Related Research

Hackman and Oldham developed the theory that the job itself should be designed to possess fundamental characteristics needed to create conditions for high work motivation, satisfaction and performance. The concepts of their Job Characteristics Theory are diagrammed in Figure 1.

Hackman and Oldham began by searching for the basic psychological states that promote high-performance motivation and satisfaction at work. The three conditions they suggested were: (a) a person must experience the work as meaningful, as something which is generally valuable and worthwhile; (b) a person must experience responsibility for the results of the work, that is, he /she must feel personally accountable and responsible for the work results; (c) a person must have knowledge of the final results of the work being done, that is, he/she must understand the effectiveness of his/her job performance. For the development and maintenance of strong internal work motivation, Hackman and Oldham (1975) assert that it is necessary for all three critical psychological states of experienced meaningfulness, experienced responsibility, and knowledge of results to be present^[1]. Since the three critical psychological states are, by definition, internal to persons, they cannot be directly manipulated in managing work. Therefore, the authors began with the question of how the critical psychological states could be created. They identified five core job characteristics of skill variety, task identity, task significance, autonomy, and feedback as reasonably objective, measurable and changeable properties of work, and that foster the desired psychological states, which in turn motivate positive personal/work

outcomes. They further suggested that skill variety, task identity, and task significance contributed to the experienced meaningfulness of the work while autonomy accounted for experienced responsibility, and feedback established knowledge of work results. A job high in motivating potential must be high on at least one of the three job characteristics that prompt experienced meaningfulness, and high on both autonomy and feedback, to create conditions which foster all three critical psychological states (Hackman and Oldham, 1980, p.81). The overall motivating potential of a job can be determined by the computation of a motivating potential score, which is calculated as illustrated below:

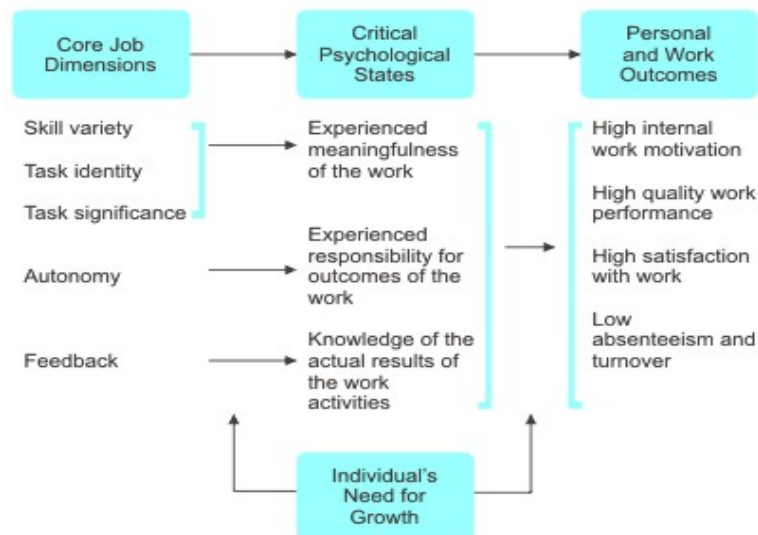

Figure 1 The Relationships among the Core Job Dimensions, the Critical Psychological States, Personal/Work Outcomes, and Moderators^[2].

2.1 Motivating Potential Score: $(\text{Skill Variety} + \text{Task Identity} + \text{Task Significance}) / 3 \times \text{Autonomy} \times \text{Feedback}$

The motivating potential score provides a quantitative diagnosis of the job situation in question by means of the scores obtained from the Job Diagnostic Survey. In summary, the Job Characteristics Theory of Hackman and Oldham asserts that a job will be meaningful to an employee to the extent that it requires a variety of skills, involves the completion of a whole and identifiable piece of work, and has significance for the lives of other people; it will foster feelings of personal responsibility to the degree that it provides the employee autonomy in selecting the methods for carrying out the work; and it furnishes the employee knowledge on which to judge the effects of his or her efforts if it is arranged to allow such feedback. Thus, the motivating potential of a job, as elaborated by the five core job characteristics, are said to affect the three critical psychological states, which, in turn, are essential ingredients of the employee's internal work motivation and other positive personal/work outcomes.

2.2 Definition of Terms: Hackman and Oldham provide the following definitions

Core Job Characteristics refers to objective properties of Skill Variety, Task Identity, Task Significance, Autonomy, and Feedback that contribute to the work effectiveness and satisfaction of employees. Critical psychological states refer to the Experienced Meaningfulness of Work, Experienced Responsibility for Work Outcomes, and the Knowledge of Work Results.

Motivating Potential Score refers to a single summary index of the degree to which the objective characteristics of the job will prompt high internal work motivation.

Skill Variety is the degree to which a job requires a variety of different activities in carrying out the work, which involve the use of a number of different skills and talents of the employee

Task Identity is the degree to which the job requires the completion of a "whole" and identifiable piece of work (i.e.; doing a job from beginning to end with visible outcomes).

Task Significance is the degree to which a job has a substantial impact on the lives or work of other people whether in the immediate organization or in the external environment.

Autonomy is the degree to which the job provides substantial freedom, independence, and discretion to the employee in scheduling his or her work and in determining the procedures to be used in carrying it out.

Feedback refers to the degree to which carrying out the work activities required by the job results

in the employee obtaining information about the effectiveness of his or her performance.

Knowledge of Results refers to the degree to which the employee knows and understands, on a continuous basis, how effectively he or she is performing his or her job.

In 2010, using the JCM in Chennai (India), Doms found that, the job dimensions highly influenced the motivating potential score [3] and also shown significant differences between his data and the normative data of Oldham, Hackman, and Stepina.

3 Methodology

Through the job characteristic model that we have presented, we analyze the employees' motivation and job satisfaction in Niger. The data for the study were based on a survey of 120 respondents from various departments of 3 sectors banking telecommunication and mining industry. These departments are: Professional or technical, managerial, sales clerical and machines trades. The respondents were asked to answer 23 questions about their job. For each question they give a score from 1 (very non descriptive) to 6(very descriptive). Then we use this information to calculate the score of the five core job dimensions we use to calculate the MPS for our analysis. We also use in the study data provided by Oldham, Hackman, and Stepina. The table 1 presents the data that we have collected.

Table 1 the 5 Core Job Dimensions the Internal Motivation Pay Satisfaction and the MPS of Different Department of the 3 Sectors

Variable	Banking					Telecommunication					Mining			
	Pr	Man	Sal	Ser	Clr	Pr	Man	Sal	Ser	Clr	Pr	Man	Clr	Mach
Skill Variety	5.4	5.8	4.2	4.9	3.8	5.2	5.6	4.3	5.0	3.6	3.0	5.5	3.5	3.2
Task Identity	3.9	5.1	4.4	4.0	5.0	4.9	4.3	4.3	4.1	5.2	2.8	4.7	5.4	5.3
Task Significance	5.0	5.9	5.5	5.7	4.2	5.7	5.8	5.9	5.8	4.2	4.9	5.7	4.0	4.2
Autonomy	4.8	4.2	4.3	4.8	3.8	5.2	4.2	4.2	4.9	3.8	4.7	4.2	3.7	3.0
Feedback	5.0	5.2	5.4	5.3	3.8	4.9	5.2	5.8	5.2	3.7	5.1	5.0	3.6	3.2
Internal Motivation	5.0	5.2	5.5	5.7	5.5	5.3	5.4	5.7	5.7	5.2	5.6	5.1	4.9	4.2
Pay Satisfaction	4.8	4.6	4.9	5.2	4.5	4.7	5.4	4.8	5.3	4.0	4.9	4.6	4.2	4.0
MPS	114.4	122.3	109.1	123.8	62.6	134	114.3	117.7	126.6	60.9	85	111	57.28	40.64

Man: Managerial; Clr:Clerical; Sal:Sales; Ser:Services; Pr:Processing; Mach: machine trades.Result

4 Result

4.1 Result 1

The comparison of the MPS score in the 3 sectors reveals that the MPS in telecommunication sector is the highest. It is just a little higher than the MPS in banking and they are both higher than the MPS in mining industries that is very low. The table 1 and figure 1 show these differences.

Table 2 MPS in the 3 sectors

Sector	Banking	Telecommunication	Mining
Mps	106.44	110.7	73.48

Figure 2 The MPS in the 3 Sectors

4.2 Result 2

The comparison between different departments in the 3 sectors shows that the MPS is higher for professional, sales and services in telecommunication than in bank. But it is higher in managerial and clerical in banking than in telecommunication. In the entire department Mps is higher in banking and

telecommunication than in mining industry. The figure shows these variations.

Figure 3 MPS of Deferent Department of the 3 Sectors

4.3 Result 3: Comparison with normative data

In an effort to establish a meaningful perspective of the data collected for this study, the means for the job were compared to normative data established by Oldham, Hackman, and Stepina (1979). The normative data are based on the results of studies involving 6,930 employees holding 876 jobs in 56 organizations. The jobs included in those studies were highly heterogeneous and divided into nine job groups established by the Equal Employment Opportunity Commission (EEOC) and defined in the Dictionary of Occupational Titles (DOT) published by the U.S. Department of Labor. Table 3 presents the core job dimensions and motivating potential score of the present study and that of the five job groups proposed (only five out of nine were considered for this study) by Oldham, Hackman, and Stepina as normative data.

Table 3 Comparison of the MPS Between the Job Dimensions of the Study and the Five Job Families Used by Oldham, Hackman, and Stepina^{[4]-[5]}

	Banking	Telecom	Mining	5 job families(Oldham et al)
Pr	114.4	134	85	105
Man	122.3	114.3	111	156
Sal	109.1	117.7		146
Ser	123.8	126.6		152
Clr	62.6	60.9	57.28	106

Figure 3 Variation of the MPS in Department of this Study and the Five Job Families Used by Oldham, Hackman, and Stepina.

The MPS of the study is higher in professional than in the normative data of Oldham, Hackman, and

Stepina. But in all the rest of the sectors the MPS of the normative data is higher.

5 Conclusions and Discussions

The following conclusions can be drawn from the results of this investigation:

1) Employees felt most strongly about their sense of work responsibility due to the autonomy experienced in doing the job.

2) Employees felt least strongly about the meaningfulness of their job due to the degree in which they felt the job required a variety of different activities, allowed for the completion of entire tasks, and the impact the job has on the lives of others.

3) Employees indicated a strong desire to experience stimulating work and the opportunity to exercise creativity and independent thought; however, their feelings towards the core job dimensions produced a low motivating potential score.

4) A job high in motivating potential must be high on at least one of the three job dimensions (skill variety, task significance, task identity) that prompt the psychological state establishing an employee's feelings of meaningfulness in his or her job.

5) A job high in motivating potential must be high on autonomy to instill the psychological state that establishes an employee's feelings of accountability and responsibility in his or her job.

6) A job high in motivating potential must be high on feedback to instill the psychological state that establishes an employee's awareness of how effectively he or she performs the job.

7) The professional of banking and telecommunication in Niger are more motivated than those in the normative data but in general employees of the normative data are more motivated than in Niger.

These variations can be explained by the cultural differences.

Study on Innovative Development Strategy for the Private Economy of Wuhan of China

Zhang Jun

School of Management, Wuhan University of Technology, Wuhan, P.R.China, 430070

(E-mail: 21137430@qq.com)

Abstract: Wuhan's private economy accounts for approximately 50% of the city's economic aggregate, but is facing unprecedented challenges and competition pressures against the backdrop of current economic globalization and the global financial crisis, insufficient development remains the biggest issue, this is most prevalently shown by the low economic aggregate, low proportion, small size, slow development, low degree of industrial agglomeration and imperfect social service system. This paper suggests that we shall tackle these problems by adhering to innovative development concepts, raising management ability, perfecting the service system, remedying the difficulties in financing, increasing policy support, optimizing the development environment and other measures, so as to promote innovative and sustainable development of Wuhan's private economy.

Key words: Private Economy; Scientific and technological innovation; Management innovation; Institutional innovation; Mathematical analysis

1 Introduction

The private economy is an important supporting strength for economic development in Wuhan. Since the "11th Five-Year Plan", Wuhan's private economy has been developing and growing stronger rapidly in terms of market competition, significantly contributing to the construction of Wuhan as a national central city. At present, research on the development of private economy countermeasures are more concentrated at the theoretical level, such as the significance of the development of private economy, strategy, corporate culture, and human resource management. Area studies are less, especially with regard to the development of private economy in Wuhan. In light of this, strengthening the study on innovative development of the private economy is fundamentally important in both theoretical and practical terms.

2 Theoretical Bases for Innovative Development

"Innovation" is a concept put forward by the economist Joseph Schumpeter, who thought that innovation is "to establish a new kind of production function", that is, introducing a "new combination" regarding production factors and production conditions which had never existed before into production system. Schumpeter thought that the main driver of innovation are entrepreneurs and the entrepreneurial spirit, his theory on includes two kinds of fundamental types, technological innovation and institutional innovation; the theory of technological innovation deems technological progress and innovation as the decisive factors for economic growth, while the theory of institutional innovation argues that technological progress plays an important role in economic development, however the theory that really plays a vital role is institutions, which exert an influence on economic development through property rights, benefit distribution, decision-making, coordination and other mechanisms. Peter Drucker (Peter F. Drucker) is also on the innovation theory, try to innovation and entrepreneurship as a purposeful, systematic knowledge to interpret its inherent law.

3 Main Results of Innovative Development of Wuhan's Private Enterprises

3.1 Continuous growth in size and strength

In the economic take-off stage, the accumulation of capital occupies the center position. In 2011, the private economic subjects registered in Wuhan were 548,700 households, with year on year growth of 14.9%. The private economy achieved an added value of RMB 277.68 billion Yuan, increasing by 12.8%, accounting for 41.4% of Wuhan's GDP, boosting GDP by 5%; private investment amounted to RMB 196.398 billion Yuan, increasing by 24%. Private investment accounted for 46.2% of the total investment in fixed assets, becoming an important force in the social investment in Wuhan.

3.2 Continual improvement of its comprehensive quality

The industrial field has been gradually expanding. From 2008 to 2011, the industries with obvious increases in terms of the proportion of actual private enterprises in Wuhan were communication and

transportation, warehousing and post services, information transmission and others, indicating that private economy made rapid development in the new fields (details are shown in Table 1).

Table 1 Sub-Sector Proportion of Actual Private Enterprises in Wuhan (2008-2011) Unit:%

Industry Classification	2008	2009	2010	2012
Agriculture, Forestry, Animal Husbandry, Fishing	0.93	1.01	1.07	1.20
Mining		0.03	0.03	0.03
Manufacturing	9.79	8.98	8.37	7.80
Production and Supply of Electricity, Gas and Water		0.11	0.12	0.12
Construction	8.13	8.34	8.65	9.24
Communication and Transportation, Warehousing and Post Services	2.57	2.66	2.78	2.84
Information Transmission, Computer Services and Software	3.83	4.06	4.17	4.34
Wholesale and Retail	35.36	34.36	33.85	33.25
Accommodation and Catering	1.68	1.62	1.53	1.48
Finance Industry		0.32	0.29	0.30
Real Estate	4.45	4.45	4.65	4.63
Leasing and Business Services	15.52	16.46	17.09	17.27
Scientific Research, Technology Services and Geological Surveys	11.94	12.34	12.48	13.07
Water Conservancy, Environment and Public Facility Management	0.54	0.50	0.44	0.38
Residential Services	3.47	3.30	3.02	2.58
Education		0.12	0.10	0.09
Health, Social Security and Social Welfare	1.03	0.18	0.18	0.19
Culture, Sports, Entertainment	0.74	1.15	1.17	1.19

Source of data: Edited by the Wuhan Municipal Statistics Bureau, Wuhan Statistical Yearbook-2012.

Year on year the number of listed companies are increased. By the end of 2011, the total number of private listed companies in Wuhan had reached 18, adding 8 to the total number in 2008; private listed companies accounted for 40% of the total listed companies, increasing by almost 10% from 2008.

3.3 Constant enrichment of innovation carriers

In 2011, the number of business incubators above the municipal level in Wuhan reached 65, 13 of which were national level business incubators, developing technological number 3,678, a large number of science-and-technology enterprises with good development prospects grew and developed into back-up listed enterprises. At present, 75 municipal engineering and technological research centers and 70 municipal enterprise research and development centers have been established, 80% of which depend on private science-and-technology enterprises.

3.4 Constant perfection of innovation policies

The speed of private economic development is closely related to national and regional systems and policies, the ideological preferences and policy orientation of the local government have a significant influence on private economic development and path selection. In recent years, the Wuhan Municipal Party Committee and the Municipal Government have introduced some policy documents in succession, including The Opinion of the Municipal People's Government on Further Supporting Construction and Development of Science-and-Technology Business Incubators and The Opinion of the Municipal People's Government on Further Encouraging and Supporting Development of the Private Economy, providing a strong guarantee for guiding and promoting innovative development of the private economy.

4 Problems in the Innovative Development of Wuhan's Private Economy

From a macroscopic view, the private economy of Wuhan has made great progress, but in recent years, the absolute value of the economic aggregate has not been big, its development speed is slowing

down, with its proportion in Wuhan's GDP stagnating. Especially compared with some areas of its kind, development speed, economic aggregate and economic aggregate proportion all lag behind relatively. (Details are shown in Table 2)

Table 2 A Comparison of the Development Situation of the Private Economy in 2009

Item	Wuhan	Guangzhou	Hangzhou	Chengdu
Private Economy Achieved GDP (RMB in hundred million yuan)	1852.43	3164.44	2676.8	2389.1
Proportion in Regional GDP (%)	40.60	52.6	64.5	53.1
Number of Private Enterprises (tens of thousands)	12.88	23.8	14.1	16.3
Individual Businesses (tens of thousands)	43.57	36.9	28.5	59.9
Gross Total of Taxes Paid in Private Economy (RMB in hundred million yuan)	192.05	491.2	370.77	236.5
Private Enterprise Average Registered Capital (RMB in ten thousand yuan)	202.09	224	267.5	222.1
Sales and Production Value of Private Industry above Designated Size (RMB in hundred million yuan)	1627.43	5978	4678.01	1411.5
Number of Private Industry Enterprises	10785	20335	18564	11653

Source of data: Wuhan Private Economic Development Report 2009

4.1 Economic aggregate is relatively low

In 2012, the private economy of Wuhan achieved added value of RMB 329.7 billion Yuan, while other cities at provincial or sub-provincial level were respectively: Shanghai RMB 488.37 billion Yuan, Tianjin RMB 517 billion Yuan, Chongqing RMB 562.29 billion Yuan, Chengdu RMB 474.5 billion Yuan, Hangzhou RMB 456.898 billion Yuan, Shenzhen RMB 410 billion Yuan, ranking approximately 10th in terms of proportion of private economy among the 15 sub-provincial cities.

4.2 Lack of size and strength

In 2012, among the top 100 enterprises in Wuhan, only 36 are private, with average operating revenue of RMB 5 billion Yuan, only 23.5% of that of state-owned enterprises. In 2012, among China's top 500 private enterprises, only 10 were from Wuhan, while in economically developed areas of Jiangsu and Zhejiang provinces, there were 24 from Wuxi, 23 from Suzhou and 21 from Wenzhou.

4.3 Economic structure is not optimal

In terms of market access, most private enterprises are centered on traditional labor-intensive industries such as manufacturing, commerce, catering, wholesale and retail industry, etc. with low entry threshold, low technology content, low added value, they are at the low end of the tertiary industry.

4.4 Industrial agglomeration is not concentrated

The private economy in Wuhan has not yet formed a relatively complete industrial chain or high-density industrial cluster. Industrial cluster features in urban industrial parks are not clear, industrial relevancy among enterprises in the parks is not high, manifesting as a kind of enterprise agglomeration with weak coordination and collaboration, the industry chain is neither complete nor strong.

4.5 Management levels are not high

In most private enterprises, management mode and corporate governance structure are a long way short of the requirements of the modern enterprise system, family-run management is popular and the rule of man phenomenon is common. Decision-making mechanisms involve a lot of arbitrary decisions made on a whim.

4.6 Financial mechanisms are not flexible

According to surveys, similar to other regions in the rest of the country, the most prominent "bottleneck" of private economic development in Wuhan is financing difficulties, insufficient capital is the biggest problem for private enterprises in Wuhan, which is prominently manifested through difficulty in obtaining bank loans, direct financing and financing guarantees.

4.7 Policy environment is poor

In the context of the market economy, the main way the local government plays a role in economic development is to provide institutional supply. The policy environment is an important impetus for innovative development of the private economy. Although in recent years the municipal government has introduced many policies to support enterprise development, but as far as execution is concerned, details

of operable implementation are still needed, so implementation of the policies is difficult. “Swinging door” and “glass door” phenomena still exist.

5. Main Strategy for Innovative Development of Wuhan’s Private Economy

5.1 Speeding up concept innovation for private economic development

First is promoting the strategic position of the private economy. It is suggested that the Wuhan Municipal Party Committee and the Municipal Government consider the development of the private economy as an important strategy to support the construction of Wuhan as a national central city, starting from the top-level design of the policy framework to boost the development of the private economy to the urban development strategy level, sparing no efforts in boosting the private economy to achieve breakthrough development. Second is encouraging the private economy to walk on the road of technological innovation. Use “professional, refined, special and new” as the important way for transforming and upgrading the private economy and transformation of the development mode. Third is to develop strategic emerging industries. Guide the private economy to participate in the development of strategic emerging industries including new energy resources, energy conservation and environmental protection, new materials, a new generation of information technology, and engage in development of modern service industries such as finance, logistics, cultural creativity, etc.

5.2 Speeding up science and technology and management innovation for private enterprises

The Local Government should promote the establishment of a market-oriented technology innovation system with private science-and-technology enterprises as the main bodies and close integration of enterprises, universities and research institutes. Small and medium-sized private enterprises can establish joint research and development institutions with universities and research institutes, or make joint efforts to build research and development institutions by way of investment holding, equity participation, etc.

First is to establish a modern enterprise system, perfect corporate governance structure and strengthen internal management. Second is to shape an enterprise culture with innovation as the internal core, making the employees form a sense of identity and a sense of belonging to the enterprise, thereby motivating employees and management teams to continually raise innovation awareness and enthusiasm for intelligent capital investment, making the enterprises constantly obtain new competitive advantages.

First is to train up a high quality team of private entrepreneurs. Entrepreneurs are the souls of enterprises; their character determines the rise or fall of the enterprise. It is essential to cultivate entrepreneurship with an innovative spirit as the essence, eternally preserving the vitality and vigor of the enterprises. Second is to perfect personnel mechanisms. Healthy private enterprises facilitate talent introduction, cultivation and employment, which creates a comfortable and harmonious innovation environment of fair competition for the majority of private enterprises.

5.3 Speeding up institutional innovation of development in the private economy

Private enterprises should make full use of the platform of national “new three board” pilot project in the East Lake Development Zone to get listed for financing. We should accomplish construction of a financial guarantee system. The local government should support the development of various forms of credit guarantee institutions, raise guarantee funds through various channels, share and manage security risks well, provide more credit guarantee and re-guarantee businesses for private investment projects.

First is to strengthen the construction of business incubators. Government departments should particularly attach importance to the construction of enterprise incubation platforms, leading to the establishment of different types of business incubation bases at different levels, funding a batch of potential and excellent entrepreneurial talents and projects. Second is to strengthen the construction of the public service platform. Further improve the service function of SME service supermarkets. Third is to establish and improve the social service system. Guide and integrate social resources, strive to develop accounting, auditing and other kinds of intermediary service agencies, providing quality social services for private enterprises. American psychologist Andy Clark believes that the system of people's choices and learning activities to provide "external stent," which coordinate people's activities and the establishment of confidence-building mechanism.

Policies are the biggest government actions. The municipal finance department should enhance the support to the private economy, increase special funds for development of private enterprises and include this in the management of the budget. The municipal tax department should earnestly implement various kinds of preferential tax policies for encouraging and supporting private economic development, carry out differentiated preferential tax policies for growing high-tech private enterprises. The municipal

human resource and social security department should give appropriate support to private enterprises on subsidy amount and payment methods regarding payment of social security fees.

The market is the main leader of innovation. The government's responsibility is to create a good environment for innovation. Therefore, it should firstly deepen the office working style; secondly, it should deepen the reform of administrative examination and approval system; thirdly, it should administer in strict abidance with the law; fourthly, it should create a positive atmosphere of public opinion, to develop and expand the spirit of innovation, creating a public opinion atmosphere conducive to innovative development.

6 Conclusion

Innovation is the power and the source of enterprise development. As a means of datas, the article indicates seven specific issues through the development of private economy in Wuhan . At the same time, the article proposes some suggestions in a targeted manner from the system and management recommendations for the relevant reference. Next, in order to make this research more practical, we will focus on innovation about resource elements, the main elements, structural elements, environmental elements and cultural elements.

Research on the Serious Transfer Path of Supply Chain Risk

Qiu Yinggui

Management school, Hubei University of Chinese Medicine, Wuhan, P.R.China, 430065

Chinese Medicine Development Centre, Wuhan, P.R.China, 430065

(E-mail: qiuyinggui@126.com)

Abstract: Cooperation among node enterprises of supply chain makes supply chain risk (SCR) transfer easily, while study on the transfer path of SCR can be helpful to the effective management on SCR. In this paper, based on theoretical analysis, the serious transfer paths of SCR are interpreted according to the transfer direction of SCR which are Positive serious transfer of SCR, Reverse serious transfer of SCR and cross serious transfer of SCR. Furthermore, the characteristics of every transfer path are deep explored correspondingly. When crisis occurs, the risk source in the supply chain can be found easily along the risk transfer paths of supply chain.

Key words: SCR; Risk transfer; Serious transfer paths

1 Introduction

The relationship of agency by agreement in supply chain makes SCR exist inevitably. The independence of the enterprise legal person and increasing cooperation among the supply chain enterprises promote the risk transfer in the supply chain^[1].

Researches on SCR transfer home and abroad mainly concern the following three aspects: the transfer mechanism of SCR^[2,3], the utility of SCR transfer^[4] and the control of SCR transfer^[5-7], among which studies on supply chain management by applying the adaptive system theory are in the majority^[8,9]. However, there are few researches studying the transfer paths of SCR. This paper attempts to analyze the different paths of SCR by adopting some concepts in physics as reference, thus explore the evolution rule of the SCR transfer, hoping to provide some reference for the effective management of risk of the supply chain enterprises.

2 Serious Transfer Path of SCR (SSTPSCR)

Supply chain refers to the value increasing chain from the initial supply to the final demand. One node enterprise transfers SCR to the next one, namely serious transfer of SCR, is the main path in SCR transfer. Defining the direction of SCR transfer from supply to demand as positive, the STPSCR can be divided into three types, namely positive serious transfer, reverse serious transfer and cross serious transfer.

2.1 Positive serious transfer of STPSCR

Figure 1 Positive Serious Transfer Path of SCR
